The virulence of the parasite from healthy individuals and when existing under pathogenic conditions.—The first point that had to be considered in studying the pathology of pneumococcic infection was whether the organism as it existed as a parasite of healthy individuals was endued with virulence in the same degree as when it was found as an actively pathogenic agent. Evidence on this matter could only be obtained by animal experiment. Micrococcus pneumoniæ although not found occurring naturally in the lower animals was actively pathogenic for many of them—the rabbit, wild and tame mice, wild and tame rats, the guinea-pig, the sheep, and the dog being all more or less susceptible to infection. The susceptibility was most marked in the rabbit least in the dog and in the other species according to their position on the list. Pigeons and poultry were according to Washbourn immune against this infection. And in testing the organism as obtained from healthy saliva its virulence for the rabbit would usually be found to be quite as evident as when isolated from, for instance, the sputum of a case of pneumonia. When, therefore, the parasite became pathogenic for its human host there was no reason to believe that infection had happened because of any sudden access of virulence to a previously harmless parasite but rather that the condition of the host had afforded opportunity which under the conditions of ordinary good health, had been wanting for the exercise of a natural pathogenic virulence. Netter, however, when studying the organism as it occurred in the sputum of cases of pneumonia found that it lost all its virulence during the fortnight immediately succeeding defervescence but regained it at the end of that time. Testing the cultures immediately after isolation from cases of recent infection in man Mr. Foulerton had found that the degree of virulence in a series of cases, including the organisms isolated from 11 cases of empyema in children one case of empyema in an adult from two cases of meningitis from three of pneumonia, from one of cellulitis, and from one case of a circumscribed abscess of the finger was fairly uniform for the rabbit. So far as man its natural host, was concerned, micrococcus pneumoniæ in its character as a normal and only occasionally pathogenic parasite resembled in some degree bacillus coli communis. The latter, although a universal and according to Burnstock, a useful parasite of the intestinal tract became nevertheless, like the pneumococcus, actively pathogenic when it found the opportunity of penetrating below the mucous membrane.

The pathogenicity of micrococcus pneumoniæ for man. The pathology of pneumococcic infection might conveniently be considered with special regard to the following points: (1) the general results of blood infection and those of the toxæmia produced by the absorption and circulation of toxins formed in the local foci of infection in the tissues or produced by cocci which had infected the circulating blood itself; (2) the direct action of the parasite on the various tissues in which it became located in the course of an infection; and (3) what might be termed the secondary results of the infection—that is to say, those results due not to any direct action of the infecting organism but arising from the new morbid conditions brought about by the infection. In the case of pneumococcic infection these last secondary effects were often of the greatest consequence; there was the effect on the right heart of the obstruction to the passage of blood through the infected area of the lung the result of sudden diminution of the surface available for the oxygenation of the blood the effect of interference with cerebral function in cases of meningitis, together with others which had no immediate bearing on the present discussion.

Toxæmia in pneumococcic infection.—With regard to the exact nature of the toxic substances produced in the course of a pneumococcic infection they knew very little, whether such were actually secreted by the cocci themselves or whether they were formed from the infected tissues by the action of the cocci. Klemperer had isolated a toxic albumose pneumotoxin from broth cultures of the coccus by precipitation with sulphate of ammonia and alcohol; formic acid was also produced in some quantity in such culture. Auld had isolated from the tissues of infected animals by precipitation with absolute alcohol an albumose and a residue soluble in alcohol and consisting mainly of an organic acid. The albumose when injected into the thorax of the rabbit set up a lobar pneumonia with pleural and pericardial effusions and when injected into the subcutaneous tissue a cellulitis; the acid residue soluble in alcohol, was innocuous. As to the action of the toxins on individual tissues so far as such action was manifested by histological changes but little was known. Carnot and Fournier described definite alteration in the cardiac muscle of the rabbit produced by the injection of small quantities of filtered toxic broth. The changes included an exaggeration of the transverse striation, with vacuolation, dissociation, and fragmentation of the muscle fibres. There was also some swelling of the connective tissue of the muscle, with a subsequent hyaline degeneration. Similar changes were to be found in the voluntary muscles. Carnot and Fournier had found in two cases of pneumonia in man changes in the heart muscle similar to those occurring in the rabbit. Maragliano, on the other hand believed that the changes found in the heart-muscle in pneumonia were not due to the direct action of toxins but were secondary to nerve lesions. There was a certain amount of evidence that changes in the motor ganglion cells might result in pneumonia. Campbell Thomson and himself when investigating the action of various bacterial toxins on the motor cells of the cerebral cortex found some indication of structural alteration in these cells, when stained by Nissl's method in pneumococcic infection. In the mouse the ganglion cells showed merely the appearance of uneven staining. In the rabbit the changes were more marked the cells were swollen and showed uneven staining irregular dark areas alternating with areas of lighter staining the nuclei were indistinct and the cell body generally had a blurred appearance. There was, however, no reason to suppose that these changes were specific or in any way peculiar to the particular bacterial toxin used such as the changes which they had found in experimental tetanus were. The changes in the pneumococcic infection nearly resembled in fact those which Campbell Thomson had found in a variety of morbid conditions in which the common factor of a high temperature came into play. Cases of post-pneumonic paralysis had been described in man, and Auld had observed paralysis of the extensor muscles of the fore-limbs occurring in rabbits at some long interval after the injection of the toxin.

The local action of the pneumococcus on the tissues infected.—The local action of the pneumococcus under the conditions of a natural infection varied according to the susceptibility of the individual infected and partly perhaps, although probably in a less degree on the virulence of the actual strain of coccus present. Carnot and Fournier had pointed out that the nature of the lesions produced by pneumococcic infection in man in the guinea-pig and in the rabbit presented a gradually ascending scale of severity, the exudation being sero-fibrinous, purulent and hæmorrhagic in the respective cases. This was, of course, only partly true. In man all three varieties of exudation might be met with; the exudation might be purulent from the first, sero-fibrinous and becoming purulent, and sero-fibrinous and remaining so; and occasionally hæmorrhagic lesions were seen. A case of extensive cellulitis of the forearm, following a wound of a finger when doing a post-mortem examination, was quoted as an example of a pure pneumococcic infection of a primarily pyogenic character. Other examples were seen in the acute but circumscribed abscesses which occurred on the fingers after cuts in the post-mortem room or the abscesses in the tonsil which were sometimes a result of pure pneumococcic infection.

Fibrinous lobar pneumonia.—The first point which had to be considered with regard to fibrinous lobar pneumonia was whether the pneumonia was merely a manifestation of a general pneumococcic infection or whether it was at first a local infection. Latterly the general tendency had been to the former view, the pneumonia being looked upon as an incident in the course of a general infective disease. Mr. Foulerton thought, however, that the usual sequence of events showed that the lung infection was the primary condition and that any general blood infection was secondary to this, and, moreover, not of such common occurrence as some had suggested. Whichever view was adopted, it was certain that it was only in a comparatively small number of cases of pneumonia that any proof, direct or indirect, of a general blood infection could be found. The most reliable statistics of the result of blood examination in pneumonia were those of Franklin W. White of Boston, U.S.A., who examined the blood in 19 cases, drawing off five cubic centimetres direct from a vein with a syringe. On transferring the blood to culture media a culture of micrococcus pneumoniæ was obtained in only three cases, and each of these three proved fatal. Two of these three cases were examined post mortem and in both evidence of general blood infection was found. In seven other cases out of the 19 which also terminated fatally and in which the blood drawn off during life had proved sterile there was no evidence post mortem of any general blood infection. Indirect evidence of general blood infection was found in a certain number of cases in which after pneumonia lesions, such as endocarditis, meningitis, or arthritis and the like, occurred in parts remote from the lungs. Amongst the more uncommon of such lesions a pure pneumococcic parotiditis must be mentioned. Fraenkel and Reiche had found the specific coccus in the kidney in 22 out of 24 cases of pneumonia examined post mortem. With regard to the causation of fibrinous lobar pneumonia, and looking upon the lesion as arising from a local infection of the lung, it was quite possible that the old belief as to "chill" or exposure to cold having some share in the causation was well founded. There was no doubt but that exposure to cold would produce some temporary congestion of the capillaries of the lungs, and under those conditions it was quite likely that there was just sufficient alteration in the cells lining the air vesicles to render them less efficient in resisting an invasion by any bacteria which might come to rest on them. The access of potentially pathogenic bacteria with the air was prevented under the conditions of normal respiration through the nostrils by the mechanism which provided for the freedom of such inspired air from bacteria. But given an attack of reflex coughing, due to the irritation set up by a congested state of the air-passages, it seemed possible that minute particles of mucus from the mouth charged with cocci, having been disturbed by expiratory efforts in coughing, might subsequently be inhaled directly into the lungs with the next deep inspiration taken through the open mouth. Another point of interest was as to the exact proportion of cases of fibrinous lobar pneumonia which were due to pneumococcic infection. Weichselbaum identified the pneumococcus in the exudation of 94 out of 129 cases examined, his results being verified by culture in 54; Netter gave the proportion at about 75 per cent. and other observers had found it to be still higher. With regard to "epidemic" pneumonia Mr. Foulerton thought that this was not usually due to a pneumococcic infection. During the last year he had examined material from cases of epidemic pneumonia then prevalent at Middlesbrough. The disease was certainly characterised by fibrinous lobar pneumonia, but none of the cases were due to pneumococcic infection and he had come to the conclusion that the causative parasite in these particular cases was a bacillus having all the characters of bacillus coli communis, a conclusion which corresponded with that arrived at by Klein and Ballard when investigating a similar outbreak of epidemic pneumonia at the same place some years previously. Fibrinous lobar pneumonia was not, of course, the only result of pneumococcic infection of the lung; there was a pneumococcic broncho-pneumonia, especially in children, and the pneumococcic perinodular pneumonia of cases of pulmonary phthisis.

Pneumococcic empyema.—The pleural effusion which occurred to a greater or less extent in probably every case of lobar pneumonia was in the majority of cases due at first to the irritation of toxins passing through from the neighbouring infected lung and not to the presence of the cocci themselves in the pleural sac. And, excepting one case which occurred in a child, he had never found the pneumococcus in a non-purulent pleuritic effusion which was sufficiently extensive to have required tapping. In adults empyema usually occurred as a complication of lobar pneumonia; in children the pleural lesion was, he thought, frequently the primary one. And considering how well cases of empyema in children did under surgical treatment it was difficult to believe that there was a lobar pneumonia underlying any large proportion of ther [illegible] s a marked difference in the [illegible] in children and adults. The two parasites which had caused a very large proportion of all the cases of empyema which he had examined were streptococcus pyogenes and micrococcus pneumoniæ; in his own cases the streptococcus had caused about 75 per cent. of the cases in adults and 25 per cent. of those in children, whilst the pneumococcus had caused about 75 per cent. of the cases in children and about 25 per cent. of the cases in adults; this was excluding a small minority of cases in which organisms other than these two were present.

Pneumococcic arthritis.—Cave had recently published an excellent paper on the Arthritic Manifestations of Pneumococcic Infection, giving details of cases in his own practice and of 30 other cases recorded. Of 31 cases 23 died and only eight recovered. In one case the symptoms of the arthritis preceded those of pneumonia, in 27 cases the pneumonia preceded the arthritis, and in three cases there was no history of pneumonia either antecedent or subsequent. In 19 cases only one joint was affected, in seven cases two joints were affected, and in two the arthritis was multiple—that is to say, more than four joints were affected. When the details of published cases were considered it was obvious that the joint affection might take one of three forms: it might be purulent from the beginning, it might be at first sero-fibrinous and then purulent, or it might remain sero-fibrinous throughout, in the last case assuming sometimes the type of an osteo-arthritis. Rendu had recorded a case of pneumococcic infection of the sterno-clavicular and knee-joints in which at the time of examination the fluid in both knees was still sero-fibrinous, whilst in the sterno-clavicular joint it was purulent. As examples of the less acute forms of pneumococcic arthritis the case recorded by Fernet and Lacapére was quoted in which an osteo-arthritis of the wrist with teno-synovitis followed an attack of pneumonia. In that case full bacteriological evidence of the nature of the joint infection was obtained. Fernet and Lorrain had previously recorded two similar cases of osteo-arthritis with teno-synovitis following pneumonia in which the diagnosis of pneumococcic infection was founded on clinical evidence only.

Pneumococcic meningitis.—A pneumococcic meningitis might be acute and purulent in character or more chronic and with a sero-fibrinous exudation. Details of an acute case were given and the rapidity with which these cases ran their course was pointed out. The sero-fibrinous form apparently occurred only in children; it was uncommon, but Levi had recorded two well-marked cases occurring in children after broncho-pneumonia, and Dr. Lazarus-Barlow would refer to two other cases. The lesions in this form might be exactly those of the basic meningitis described by Still, which was in his cases undoubtedly due to diplococcus intracellularis meningitidis of Weichselbaum. The points of differential pathological diagnosis between the forms of cerebro-spinal meningitis due to infection by streptococcus pyogenes, diplococcus intracellularis meningitidis, and micrococcus pneumoniæ were referred to. Streptococcus produced only a purulent meningitis, whilst the other two produced either a purulent or sero-fibrinous form. In the purulent form the lesions were very similar whichever organism was present; there was the same purulent infiltration of the pia mater extending over the base of the brain and most marked on the dorsal aspect of the cord. Councilman, Mallory, and Wright had pointed out that in the pneumococcic and streptococcic forms the inflammation did not tend to spread from the pia mater into the substance of the brain or cord, as in the case of infection by diplococcus intracellularis; in the first two forms there was, however, an amount of endarteritis of the pial vessels not found in the other. Epidemic cerebro-spinal meningitis was probably never due to micrococcus pneumoniæ, the diplococcus intracellularis meningitidis being the organism always present in such cases. Pneumococcic meningitis might be the only lesion present, or it might be secondary to pneumonia, to otitis media, or to fracture of the base of the skull passing through the middle ear.

Pneumococcic peritonitis.—This, like many of the other manifestations of pneumococcic infection, might occur under two forms, the sero-fibrinous and the purulent. It was most frequently met with in children, only two out of 17 cases quoted by Dieulafoy having occurred in adults. Ménétrier and Legroux had recorded two additional cases in one which illustrated the two types which the peritonitis might assume. In one case in which the patient died eight days after the onset of symptoms, the peritoneal exudation was found to be purulent; in the other in which the patient died some five weeks after the onset of symptoms the exudation was sero-fibrinous and the visceral peritoneum was covered with a layer of lymph. The latter case was remarkable also from the fact that embolism of the left brachial, the right popliteal, and the left Sylvian arteries had occurred. Amongst children peritonitis from this cause was most common in girls, whilst the cases recorded in adults had been in males.

The other manifestations of pneumococcic infection which were briefly referred to were pericarditis, endocarditis, salpingitis, keratitis, and otitis media. Mr. Foulerton concluded with a reference to the method of testing the serum reaction in pneumococcic infection, as devised by Bezançon and Griffon.

The PRESIDENT (*Dr. J. W.* WASHBOURN) *thought that the* pneumococcus might certainly exist outside the body, but in a non-virulent condition. He gave an account of several cases of pneumococcic pleurisy. He was not satisfied as to the isolation of toxic substances from cultures of the pneumococcus, having failed to isolate any toxic albumose himself. In conjunction with Dr. Eyre he had carried out experiments to test the value of the serum reaction in pneumonia but without any useful results.

Professor MICHELL CLARKE (Bristol) showed and commented on some cases of purulent pneumococcic meningitis; he also showed a specimen illustrating an uncommon complication of pneumococcic empyema, extensive thrombosis of the left axillary vein.

Dr. J. H. BRYANT (London) had had the opportunity of investigating three cases of pneumococcic peritonitis, two in young girls and one in an adult male. In the last case both pneumococci and streptococci were present.

Dr. E. J. CAVE (Bath) referred to his work on pneumococcic arthritis and recorded an additional case which had occurred in his practice since the publication of his paper.

Dr. LAZARUS BARLOW (*London*) referred to two cases of posterior basic meningitis in infants from which pure cultures of the pneumococcus had been isolated. Clinically and anatomically these cases had resembled those described by Still as due to infection by the diplococcus of Weichselbaum. His cases, however, showed that the condition of posterior basic meningitis in children might be caused by more than one organism.

Dr. J. W. EYRE (London) referred to the method which Dr. Washbourn and himself had elaborated for determining the virulence of cultures of the pneumococcus by diluting a loopful of culture from a solid medium and they had been able to establish a standard of normal virulence for the organism. Using their own method they found that there was considerable variation in the virulence of cultures from different cases.

Dr. GEORGE BATTEN (London) recorded a case of cerebral abscess from which a man died eight months after an attack of pneumonia. The abscess was of the size of a small orange and was situated in the anterior part of the right cerebral lobe. The symptoms produced had been very indefinite. The pus of the abscess contained the pneumococcus and some staphylococci.

Dr. THEODORE FISHER (Bristol) called attention to the occurrence of abscess of the lung in pneumonia; he did not think that this complication was as uncommon as was generally stated to be the case. He had met with such abscesses in five cases, in all of which a mixed infection was present, the pneumococcus with bacillus coli communis or with streptococci.

Mr. FOULERTON replied, referring to various points raised in the discussion.

Dr. R. H. STEEN (Chichester) gave a demonstration on a new Electro-thermal Paraffin Bath which had been found useful when a supply of gas for heating an oven could not be obtained. The temperature was kept remarkably constant and the range of variation was not appreciable with an ordinary thermometer.

Dr. J. W. EYRE read a paper, Further Notes on Media of Standard Reaction. Dr. Eyre described his methods in detail and laid especial stress on the necessity for a somewhat prolonged heating of the meat infusion employed, in order that a maximum acidity before the final standardisation might be obtained.

Professor GLEY (Paris) read a paper on Variations of Iodine in the Thyroid in Graves's Disease and principally in the Blood after Removal of the Thyroid.—Mr. WALTER EDMUNDS (*London*) *took part in the discussion which* followed on the reading of Professor Gley's paper.

Dr. WILLIAM HUNTER (London) read a paper on the Diagnosis of the Presence of Bacillus Coli Communis by Means of Neutral Red.

OPHTHALMOLOGY.

THURSDAY, AUGUST 1ST.

Mr. J. B. LAWFORD *(London), in opening the discussion on*

The Relation of Gonorrhœa to Diseases of the Eye exclusive of Purulent Ophthalmia,

said that although the gonococcus had been found in inflamed joints and serous membranes its presence had not been *demonstrated in the eye apart from gonorrhœal ophthalmia.* Modern observations tended to show that mild conjunctivitis sometimes came on during an attack of gonorrhœa not due to the gonococcus, although possibly due to inoculation with an attenuated virus. The association of iritis and irido-cyclitis with gonorrhœa had been long recognised. In many cases it occurred concurrently with arthritis, though not invariably. Both were liable to relapse without any fresh infection. Scleritis and episcleritis were not so frequent and still less so were retinitis and neuro-retinitis. In the former there was a possibility of embolic infection. One or two instances of bilateral infection of the lacrymal gland were on record.

Mr. E. J. HAMILTON (Liverpool) described a case of gonorrhœal iritis in which there was no arthritis.

Dr. R. A. YELD (London) had recently analysed 159 cases of iritis. In 28 patients there was a history of gonorrhœa and 26 had arthritis as well. In 13 cases there co-existed iritis, arthritis, and gonorrhœa. 8 per cent. were therefore attributable to gonorrhœa. Conjunctivitis was a common complication; the great difficulty was to exclude syphilis as a factor.

Dr. DARIER (Paris) had seen many cases of iritis associated with metritis and endometritis not proved to be gonorrhœal which subsided with the cure of the uterine trouble.

Mr. HENRY POWER (London) thought that cases of gonorrhœal iritis must be very rare.

Mr. RICHARDSON CROSS (Bristol) considered that there was no doubt about the occurrence of gonorrhœal iritis and had frequently met with it.

Major H. E. DRAKE-BROCKMAN, I.M.S., said that he had seen instances of gonorrhœal iritis complicating gonorrhœal ophthalmia.

Mr. SYDNEY STEPHENSON (London) said that he had recently seen two cases of gonorrhœal conjunctivitis with arthritis.

Mr. DEVEREUX MARSHALL (London) described the exudation in the anterior chamber in these cases [illegible] found the gonococcus present there.

Mr. L. V. CARGILL (London) drew attention to the numerous cases of rheumatic iritis in which there was no history of gonorrhœa.

Mr. G. W. ROLL (London) questioned Mr. Lawford on his *experience of the use of salicylate of soda in these cases.*

Mr. LAWFORD, in reply, said that he had not seen this form of iritis in females. He thought that in cases of gonorrhœal iritis complicating gonorrhœal conjunctivitis cro could not positively exclude a solution of continuity in the surface.

Dr. C. S. Blair (London) exhibited a New Portable Refractometer.

Mr. G. W. Roll made some observations on Hess's Operation for Ptosis suggesting some slight modification of the insertion of the sutures, placing them nearer to the edge of the lid.

Mr. R. J. Coulter (Bristol) described some interesting Visual Fields. He showed tracings taken from patients with various diseases of the optic nerve and other lesions, functional and organic. He strongly advocated the use of *black* spots for use with the perimeter.

Mr. G. Hartridge (London) thought that too large an object was used with the perimeter and that the size should be stated.

Mr. L. V. Cargill read notes on Ophthalmic Experience in the Imperial Yeomanry Hospital in South Africa, exhibiting specimens of eyes and projectiles which had injured them. He described the most frequent forms of injury, including some of the cervical sympathetic.

Mr. Henry Power pleaded for the

Occasional Employment of Depression for the Cure of Cataract.

The operation was universally adopted in days gone by and many native operators still used it, often with brilliant success, even in the absence of antiseptic precautions. In early days he had both witnessed its performance by others and practised it himself. The dangers of the operation were greatly exaggerated. He did not advocate its revival in ordinary cases or where there existed adhesions of the iris, but he thought it might be undertaken in very old and feeble people, in small and depressed eyes, in cases of incurable chronic conjunctivitis, in complete deafness where the patient could not be made to understand the details of after treatment, in lunatics, sufferers from chronic bronchitis, in cases of tremulous lens with fluid vitreous, in cases unsuccessfully operated upon, and, lastly, in cases of hæmophilia.

Lieutenant-Colonel J. L. Poynder, I.M.S., stated that he had seen a great many cases of couching, but usually the patients came to him on account of serious complications which had followed after the operation had been done by natives. He thought that in many cases in India it was justifiable. The puncture was usually made through the cornea.

Mr. Richardson Cross had tried the operation in tremulous irides with fluid vitreous.

Mr. Dykes Bower (Gloucester), Mr. G. W. Roll, Mr. Tatham Thompson (Cardiff), and Mr. G. Hartridge also spoke.

Mr. Power, in reply, said that he always punctured through the sclerotic, first tearing the posterior capsule and then passing the needle in front of the anterior.

Mr. R. J. Hamilton, in describing the

Treatment of Hypopyon Ulcers of the Cornea,

advocated the local division of blood-vessels near the ulcer and application of leeches to the outer canthus. The actual cautery was of the utmost value and gave the patient much relief: other local treatment he considered to be of little use.

Mr. Richard Williams (Liverpool) said that he only occasionally evacuated a hypopyon in severe cases, preferring a small linear incision to Saemisch's section. He approved of the use of quinine.

Mr. Tatham Thompson thought the influence of bad surroundings was very serious in infective ulcers of the cornea. 1 in 5000 formol was now his favourite remedy.

Mr. H. E. Jones (Liverpool) said that he saw the condition frequently in colliers. He had almost entirely given up the cautery.

Dr. Darier strongly advocated the galvano-cautery and in some cases the sub-conjunctival injection of cyanide of mercury.

Mr. Dykes Bower recommended the use of the galvano-cautery and fluorescin; a general anæsthetic was essential.

DISEASES OF CHILDREN.

Thursday, August 1st.

This section resumed its work (all its officials being present) by Dr. F. Foord Caiger (London) opening a discussion on

The Early Diagnosis of the Acute Specific Fevers.

He began by emphasising the necessity for early diagnosis in this class of cases so as to secure prompt isolation. His first group comprised those acute specific fevers associated with catarrh of the naso-pharynx, such as rubella, measles, feverish colds, and whooping-cough. In measles, besides the cold in the head and watery eye, there was often a blotchy condition of the face a day or two before the rash came out. In measles after scarlet fever the rash frequently came out on the first day. In rubella there was occasionally malaise for some days before the appearance of the rash. The nasal catarrh was slight, the throat symptoms were slight, and there was no catarrh of the fauces or the bronchial tubes. Often there was enlargement of the glands in the posterior cervical region sometimes below the mastoid or at the angle of the jaw. The fever was slight and transient. The main difficulty in the diagnosis was deciding about the rash. In rubella the spots were smaller, rosier, raised, and less persistent than they were in measles. In measles Koplik spots were valuable. They were minute bluish-white specks on the buccal mucous membrane, nearly opposite the molar teeth, never on the palate. They appeared three or four days before the skin eruption. Later they might get surrounded by a definite red areola. They were not aphthous but a part of the general endanthem in measles. Observers had given 165 cases of measles in which in every case these spots had been seen and another set of 266 cases where 244 showed them. His own experience was not so satisfactory. In whooping-cough sometimes the sickness (apart from the cough) was an early symptom, then the paroxysmal cough (especially at night), the puffiness round the eyes, viscid sputa, and nervous symptoms, such as bed-wetting, were valuable. A peculiar bacillus had been found in the sputum. He then discussed the symptoms of laryngeal catarrh, croup and membranous croup, and diphtheria. Throat affections were common in diphtheria, scarlet fever, and tonsillitis. The bacteriological test was the only real one, though surrounded by many difficulties. (1) The Klebs-Löffler bacillus was found, not definite clinical symptoms; then not conclusive save by animal inoculation: (2) the same with clinical symptoms of diphtheria could be taken as quite correct; (3) no bacilli (on two separate occasions) and clinical symptoms negative, equals no diphtheria; (4) no bacilli could not be accepted as negative if the clinical symptoms were well marked. The Neisser stain was recommended as very distinct. Follicular tonsillitis showed the exudation in spots not coalescing, and limited to the tonsils; there would be no albuminuria and more fever than was common in diphtheria. There might be a slight rash, not punctiform, and not lasting 24 hours. In scarlet fever generally there was a sore throat from the onset, which in four-fifths of the cases was accompanied by vomiting. The tongue was creamy white, which later cleared of, leaving a brick-red shiny surface. He then alluded to the two types (one sometimes called the fourth disease) of rubella—one like measles and the other like scarlet fever.

The President (Mr. Frederic Eve, London) asked if there was any diagnosis between surgical scarlet fever and septicæmia.

Dr. E. W. Goodall remarked on the prodromal rash in measles, much like a scarlatiniform rash, but not punctiform or very slightly so, which faded before the real measles rash came out; it was a diffuse brilliant erythema on the trunk on the first or second day of the attack. The ordinary eruption of scarlet fever was not punctate at first. There was a similar prodromal eruption in varicella on the first day, and occasionally this rash came out after the real rash was evident. Was there a rash in acute pneumonia, as cases were sometimes sent to the fever hospital with this complaint for scarlet fever? Sometimes in measles, after one or two days of catarrh, a complete remission of all symptoms occurred. The Koplik spots were not always present. In a child with laryngeal symptoms, where there was no definite history, treat as diphtheria. He quite agreed with Dr. Caiger on the value of bacteriological examination. In a large number of cases of scarlet fever there was no sore throat (children, also, often did not complain of it), so that the diagnosis was very difficult. Where a patient had continued pyrexia, with early vomiting and delirium, and did not yield at all to antitoxin, it would be wise to suspect scarlet fever.

Dr. H. Ashby (Manchester) considered that everything should be taken into account in making a diagnosis. His experience of the Koplik spots was not satisfactory. He believed measles to be infectious from the first day of the disease. He had often seen influenza in children attended by a paroxysmal cough, closely simulating whooping-cough, without the whoop. Enlarged glands at the angle of the jaw would always suggest diphtheria or scarlet fever, even though there was no appearance of disease in the throat. The diagnosis of scarlet fever in a surgical ward was full of difficulty. Acute pneumonia, especially of the cerebral or gastric kinds with little physical signs, and those apical with hyperpyrexia and vomiting, closely resembled scarlet fever before the rash came out. As to the fourth disease there were cases of this (or the scarlatiniform kind of rubella) which had got scarlet fever afterwards, tending to show that they were not the same disease.

Dr. F. J. POYNTON (London) had seen cases of fourth disease with hardly anything to distinguish them from mild scarlet fever. Swelling of the posterior cervical gland was an early symptom of German measles and a prodromal rash, a faint and abortive edition of the real exanthem, went off in a day or two before the real one came.

Dr. W. J. TYSON (Folkestone) considered it a great mistake to be too dogmatic in diagnosis of these difficult cases and dealt with the cases called in old times gastric and low fever; these he thought were really due to toxin absorption and had nothing to do with typhoid fever.

Dr. WATSON WILLIAMS (Clifton) showed two good coloured sketches of Koplik spots and said that he had never found them in German measles nor had he seen them in any suspected cases of measles which did not prove to be real measles afterwards. He had seen all varieties of German measles from the morbilliform to the scarlatiniform kinds, and considered that the two extremes were rather varieties of rubella than that the latter kind was another (the fourth) disease.

Dr. LOVELL DRAGE (Hatfield) said that the scientific position of the acute specific fevers should be always taken into consideration. One should look on every sore throat as a possible diphtheria. Bacteriology so far from helping had, in fact, muddled the diagnosis. He ended by referring to the measures taken to suppress the plague at Glasgow.

Dr. MANSEL SYMPSON (Lincoln) had always found the posterior cervical glands enlarged early in German measles. He noted that the rash came out behind the ears and around the nose and mouth; sometimes it had rather the size and shape of the measles spots, but with the scarlet fever colour. He had been much helped in diagnosing scarlet fever by the 'circumoral pallor' described by Dr. Caiger. An early sign in scarlet fever was the great heat of the skin to touch. This occurred also in acute rheumatism and in acute pneumonia. The last disease (when of the gastric or cerebral type described by Dr. Ashby) in children often had no physical signs for two or three days after the onset of the illness, and so might reasonably be placed among the acute specific fevers. Not much was heard nowadays of these fevers beginning with fits of convulsions. He lately saw three children in one family all taken ill on the same day, of whom two died in fits and the third developed typical scarlet fever. He related a case of diphtheria which apparently had developed in the lung and travelled outwards to the larynx and tonsils. In an analysis of cases of diphtheria in Dr. Gee's wards at St. Bartholomew's Hospital during a period of 10 years which the speaker had made some years ago he found that the most constant sign of the disease was swollen glands at the angle of the jaw.

Dr. CAIGER replied. He considered the surgical scarlet fever alluded to, a diffused erythema in children, to be really scarlet fever. There was a septic rash due to absorption which was rather of the morbilliform kind of eruption than scarlatiniform. He would say, "No Koplik spots, then not measles." The prodromal rash of measles came on during the early febrile stage; very often a distinct scarlatiniform eruption was very likely to mislead. The Koplik spots must not be mistaken for flakes of milk, buccal glands, air bubbles, or the orifice of Steno's duct. Where in scarlet fever there was a sore throat early or a late rash the throat very probably was the cause of the scarlet fever and so not a scarlet fever throat at all. Also it might be a conjunction of scarlet fever and diphtheria which was always dangerous. Frequently there was a "kick up" temperature in the incubation state of measles. The spasmodic cough in influenza was very like that of whooping cough. He was very doubtful if the later stages of desquamation in scarlet fever were dangerous. He was inclined to class the fourth disease when there was much peeling with scarlet fever.

Dr. J. H. THURSFIELD (London) read a paper on Widal's Serum Reaction in the Diagnosis of Typhoid Fever in Children. Out of 100 cases 42 gave positive reaction. It seemed to be a valuable and trustworthy aid in the early diagnosis of typhoid fever in children.—Dr. CAIGER congratulated Dr. Thursfield on the very satisfactory results.

Dr. SINCLAIR WHITE (Sheffield) then read an excellent paper on the Ultimate Results of Tendon grafting in Infantile Paralysis, which was discussed by Mr. F. C. ABBOTT (London) and Mr. A. H. TUBBY (London) and Mr. WHITE replied.

Mr. F. C. ABBOTT produced a Specimen and Photographs of a very interesting case of Intra-uterine Rickets.

LARYNGOLOGY AND OTOLOGY

THURSDAY, AUGUST 1ST

Dr. MIDDLEMASS HUNT (Liverpool), Dr. BARCLAY BARON (Bristol), and Mr. RICHARD LAKE (London) opened a discussion on

The Local Treatment of Tuberculosis of the Larynx.

Dr. MIDDLEMASS HUNT said that it was 11 years since the subject had been discussed by that section of the Association. In 1890 the epoch-making work of Heryng on "The Curability of Laryngeal Phthisis" had not long been published. Although all the bright hopes with which the writings of Krause and Heryng had inspired them had not been realised a great and permanent advance in the treatment of a desperate disease had been made and they must not go back. In every case of laryngeal phthisis he tried to determine whether it was one for curative or for palliative treatment. Curative treatment as he understood the term, he said, was essentially surgical. It meant the removal of all diseased tissues by cutting instruments or their destruction by caustics, such as lactic or chromic acid. Palliative treatment included all antiseptic and local anæsthetic applications and was only occasionally surgical, as when the necessity arose to relieve dyspnœa or severe dysphagia. The cases suitable for curative treatment were those of limited disease and of hypertrophic form indicating local resistance, cases in which the lung disease was slight and stationary or only very slowly progressive, the general health and appetite good, the patient free from fever, and of a courageous and hopeful temperament. The treatment must be strictly palliative, he said, whenever the ulceration and infiltration were extensive and with much œdema or perichondritis, also when there were high fever, loss of appetite, advancing lung disease, or evidence of the patient being deeply stricken. In his opinion neither lactic acid nor any other application would remove an infiltration covered by unbroken mucous membrane. Wherever they had well-defined or at least limited infiltration without ulceration, a mass of granulations or a distinct tumour formation, the first step must be the thorough removal of the diseased tissue by the curette, followed by an application of lactic acid. He had seen rather free hæmorrhage after using the cutting forceps. He had never performed the extensive operations advocated by some but had confined himself to cases in which there had been some probability of removing the whole of the diseased tissues by curette or forceps. He considered that it was of little use to employ solutions of lactic acid of less strength than 50 per cent. and if it were tolerated it was better to go on rapidly to pure acid, healing being often hastened by first thoroughly curetting the ulcerated surface. Speaking of palliative treatment, he said that although it might not be possible to eradicate or to arrest the disease, much could be done to relieve suffering; an untreated case of laryngeal phthisis went more rapidly to the bad and with more suffering to the patient than a treated one. It was a difficult question to decide to what extent surgical means might be used in the palliative treatment of the disease. The incision of an inflammatory œdema of the arytenoid or epiglottis, which was first practised by the English physician Marcet, was a rational surgical procedure which would often relieve dysphagia and was not followed by ulceration as was at one time feared on purely theoretical grounds.

Dr. BARCLAY BARON considered the question of the extent to which laryngeal tuberculosis could be looked upon as curable. Cure, he said, could be looked for only in those cases in which a favourable pulmonary and constitutional state existed and only in a small proportion of all such cases where lung and larynx were both attacked. Local treatment alone, he said, would not suffice to effect a cure; it must always go hand in hand with general treatment. The alve of local treatment he described as threefold; first, to attack and to destroy by direct surgical and topical medical treatment the bacilli; secondly, by giving rest to the affected organ and by protecting its tissues from irritation and inflammation to restore the natural resistance to disease which if attacked by bacilli they had largely lost, and so indirectly to destroy the bacilli; also to help tissues not yet attacked to retain their health and so prevent spread of the mischief; and thirdly, in cases in which one was not able to do much in either of these directions, to ameliorate symptoms of which the most important was dysphagia. In the early stage of the disease local treatment, he said, should be of the mildest possible character. It should merely consist in giving such instructions to the patient as would give rest to the organ, and in every way should be that suitable for a simple laryngitis. In the next stage, that of infiltration, the larynx must be shielded from all irritation, including that of too much use of the voice, and purposeless cough must be stopped by suitable drugs, such as codeia, cocaine, and menthol. In the third or ulcerated stage of the disease local treatment, he said, was most definitely valuable. Many drugs had been recommended to set up a healthy and healing action in ulcerated and necrosed structures, but he had not found any of them so thoroughly satisfactory as lactic acid.

Mr. Richard Lake observed that 15 per cent. only of cases of laryngeal phthisis could be cured by surgical treatment. Speaking of the removal of the epiglottis when diseased, he said it had been brought to his notice that the operation he had described had been previously performed by others.

Dr. A. McCall (Bournemouth) spoke of the good results he had obtained by insufflating a mixture of resorcin and orthoform, using two parts of the former and one of the latter; this he found led to diminution in granulation tissue and to an improvement in voice.

Dr. Jobson Horne (London) said it was difficult to overrate the importance of the subject; it was also difficult to overstate the frequency with which it had been discussed, but that it was still more difficult to arrive at any very precise conclusions from what had been published as to the lines of treatment to be followed. The extreme surgical measures that had been recommended by some he considered were not remediable and at the best could only be regarded as mechanical means of overcoming physical difficulties which comparatively seldom occurred. He laid stress upon the pathological fact, which he had himself observed, that by the time the larynx was so extensively involved in the disease as to require surgical treatment cavitation of the lung was already established, so that in treating the larynx it was important to bear in mind that it was only a part of a diseased respiratory tract. In the more chronic form of tuberculosis of the larynx, in which thickening of the mucous membrane occurred without ulceration, he was opposed to a breach of surface being made by curetting, by punch forceps, and similar instruments, inasmuch as the hyperplasia constituted a protective action of the epithelium and submucosa, which was to be hoped for and encouraged. He referred to tuberculin as of assistance in bringing about a condition which would favour the quiescence or arrest of the disease, and in the more advanced cases with destruction of tissue he had found it of help in rendering localised lesions more amenable to surgical treatment.

Dr. Watson Williams (Bristol) considered that surgical treatment was of service in those cases in which there were definite tuberculous tumours and growths requiring removal. He recommended injections of guaiacol and olive oil: he also agreed that it was best not to injure unbroken epithelium. A case was narrated showing the value of sanatorium treatment. He insisted upon rest of the larynx being as absolute as possible, even whispering to be prohibited. Insufflations of morphine would allay a useless cough.

Dr. StClair Thomson (London) said that when they got down to the bed-rock of the whole matter the results of the so-called surgical treatment were poor, and that more definite information was required about the cures that had been worked; bare statements such as "gratifying results" and "patient died cured" were insufficient. He took exception to the statement that curative treatment was essentially surgical. He pointed out the importance of rest in view of the fact that the observations recently made all pointed to the frequency with which the disease affected the region of the arytænoid articulation. Hope of success must not be placed in treating what might be roughly called the third stage, but in an earlier diagnosis together with open air and rest.

Dr. R. H. Woods (Dublin) showed instruments for the local treatment with lactic acid and reported a case of Thyrotomy for Laryngeal Tuberculosis.

Dr. F. de Havilland Hall (London) considered that lactic acid promised definite relief to a certain proportion of cases. He had not gone in for the major surgical treatment. Where there was a breach of surface lactic acid might be used with or without curetting; where there was no breach of surface he did not advise curetting. He thought it was better to begin with a 25 per cent. solution of lactic acid and rapidly to increase the strength of the solution and, if necessary, the part to be treated could be thoroughly cocainised previously. He spoke of the value of orthoform and of the relief it afforded being more lasting than that of cocaine. He also agreed with the previous speakers who had urged the necessity for obtaining definite information about results; this, he thought, might be ascertained in London by the cases being brought before the Laryngological Society before, and twelve months after, surgical treatment.

Dr. W. Permewan (Liverpool) considered that the lack of progress in the treatment of laryngeal tuberculosis was due to no definite and reliable statistics being available. He did not employ the extreme surgical measures that had been recommended and was of the opinion that some cases were made worse by interference; he adopted rather a palliative course of treatment and had found that localised lesions benefited most.

Dr. J. Donelan (London) considered that better results could be obtained by cases being treated in institutions.

Dr. W. Milligan (Manchester) also spoke in favour of more definite information about results being obtained.

Dr. Adolph Bronner (Bradford) recommended formalin being used either by a spray or local application, commencing with a solution of the strength of 1 in 1000, to be gradually increased to 1 per cent.

Dr. N. C. Haring (Manchester) considered that possibly surgical treatment often hit the happy moment when the disease was becoming arrested, and thus they were liable to give more credit to treatment than was due.

Mr. C. A. Parker (London) said that if the part was previously cocainised pure lactic acid might be applied, and without fear of excessive reaction. The reaction was more commonly insufficient; when this was the case pure chromic acid might be used by way of gaining time. The larynx, he thought, might re-infect the lung, therefore, if the lung was in a quiescent state it was better to treat the larynx.

Dr. Middlemass Hunt, in replying, hoped that there would be an expression of advance having been made in local surgical treatment.

Dr. Barclay Baron considered that in enforcing absolute rest of the larynx they must be logical in the local treatment recommended.

Mr. Lake said that his statistics were incomplete and that owing to the patients having been lost sight of it would be difficult to complete them.

The President (Mr. T. Mark Hovell), in summing up the discussion, said it was important that local and general treatment should be combined and that no cure would be obtainable so long as the disease was active in the lungs.

Dr. Adolph Bronner read the notes of a case of

Recurrent Papillomata of the Larynx in an Adult treated locally by Formalin.

Recurrent papillomata of the larynx, he said, were most difficult to cure as they almost invariably recurred after removal. In children tracheotomy was the successful method of treatment. In adults tracheotomy was not only more dangerous but also impracticable for other obvious reasons. Many local remedies had been recommended but with no success. Dr. Bronner had recently treated a case with formalin; this had seemed to prevent recurrence. The patient, a man, aged 45 years, was seen in June, 1896; he had been hoarse off and on for over two years and was steadily getting worse. Both vocal cords were covered with typical papillomata. These were removed by forceps every two to three months. Various local remedies—e.g., lactic acid, nitrate of silver, &c.—had been tried. In December, 1897, the patient had a severe attack of laryngeal spasm and hæmorrhage, which nearly proved fatal. In December, 1898, a large number of growths were removed A spray of formalin, 1 in 1000, increasing up to 1 in 100, was ordered In March 1899, a few growths were removed Since then there had been no recurrence of the growths The vocal cords were thickened and irregular, but the voice was fairly good

Dr N C HARING read a paper on Multiple Papillomata of the Larynx

TROPICAL DISEASES

THURSDAY AUGUST 1ST

The VICE PRESIDENT (Mr JAMES CANTLIE, London) was in the chair

Malaria and its Prevention

The following papers on malaria were read

His Excellency Sir WILLIAM MACGREGOR K C M G, M D Aberd, Governor of the colony of Lagos read notes on Anti Malarial Measures now being taken in Lagos He remarked first on the importance of the subject of malaria in relation to Lagos and the advantage which would follow the control of malarial fever In Lagos steps had been and were being, taken as follows As a preliminary every effort was being made to spread knowledge of recent malarial doctrine among Europeans and natives by pamphlets lectures, and teaching in school and thus considerable interest in the subject had already been evoked In active operations the greatest attention was being given (1) to prevention by administration of quinine, (2) to the use of gauze netting, and (3) to attacking the mosquito in its breeding ground As regards quinine most Government officers took it regularly Some could not take quinine because of intolerance and he himself thought that the taking of quinine should be compulsory among Government servants and that they should be tested as to toleration before being engaged Judging from results it would seem tolerably certain that by the regular use of quinine as a prophylactic officers could be kept practically free from malarial fever The great difficulty was to extend this preventive treatment beyond the service, more particularly to natives but it was found practically impossible, on the ground of expense and the unwillingness of many natives to take it to give quinine to the whole population As regards mosquito netting reasons were given why such good results as had been obtained in Italy could not be expected in Lagos Limited operations were however, being carried out in this direction in Lagos With regard to the attack on mosquitoes, swamps were being gradually filled up kerosine was being used on anopheles pools water tanks of houses were being made mosquito proof, undergrowth was being thinned out and the lower branches of the large trees removed and general sanitary measures were being carried out in the town and along the railway Sir W MacGregor stated that from the more free use made of water in their neighbourhood the quarters of Europeans were more infested with mosquitoes than those of natives For six months in the year during the dry season there was practically no propagation of the mosquito in the interior, and it might be practicable to exterminate mosquitoes in the hinterland were it possible to prevent their production near and arrival from the coast The strong recommendations that Europeans should live away from natives, which he said might be called the academic recommendation, he was unable from his point of view as an administrator for reasons fully given in the paper to accept Sir William MacGregor concluded by remarking that though the measures taken in Lagos were no doubt far less than the measures required still if they were persevered in for two or three years their effect would undoubtedly be felt and encouragement would be given to steps on a greater scale It must not be forgotten that malaria was not the only disease that caused large mortality in Lagos and that large expenditure had to be incurred with reference to other diseases notably dysentery

children, and breeding pools for anopheles were found in the neighbourhood The seasonal increase of cases of malarial fever during the time of ploughing and harvesting the rice crops was due to the disturbance at these times of mosquitoes usually resting among the grass or growing paddy (rice) and feeding on the Chinese coming within their reach Dr Young pointed out the practical impossibility of dealing with mosquito larvæ by any germicides and regarded the latter merely as useful auxiliaries in extermination of the pests He regarded permanent good in this direction as possible only by clearing all long grass and undergrowth and destroying all breeding places by draining, &c A cleared area he considered of the first importance as no mosquito would fly far from vegetation, and he fixed 160 yards as sufficient clearance around houses as beyond that distance it was doubtful if mosquitoes would fly

Captain C J FEARNSIDE, I M S, read a paper on the Inoculation of Malaria by Anopheles He said that the central prison of Rajahmundri Madras Presidency, was one of the most malarious jails in India and from the years 1880 to 1897 no less than 60 per cent. of admissions for malarial fever in all the larger jails of that Presidency were accounted for by this prison In 1899 Dr Manson suggested that he (Captain Fearnside) should make investigations to see how far the anopheles mosquito was the bearer of the malarial organism In November last he dissected 40 free anopheles which had at some time or other been feeding on the blood of the prisoners and he found malarial sporozoites in one—i e 1 in 40 The sporozoites were very numerous in the veneno salivary gland from the tenth to the twelfth day after infection From the fifteenth day after incubation the numbers decreased so that there were few sporozoites in the gland on the nineteenth day The infected mosquito could only infect a limited number of persons and further to give a successful inoculation a considerable number of sporozoites must be infected because if a small number only found their way into the blood the phagocytes destroyed them Of 17 anopheles fed on blood containing summer autumn parasites and crescents nine were found to contain Ross's cysts The failures he had explained and the conclusion was that 70 per cent approximately became infected Of seven fed on blood containing spring tertian parasites all became infected Eight persons were inoculated and of these seven contracted fever The blood on which the anopheles fed originally was examined and the parasite recorded the blood of the person inoculated was examined from time to time and also recorded The incubation period was from 12 to 25 days for both types of fever The prevention of the spread of malaria by means of wire protected houses and mosquito curtains was out of the question in India To put the native population men women and children who sometimes had only sufficient money to keep body and soul together under mosquito nets and in mosquito proof houses was impossible The next suggestion then one heard of was the destruction of anopheles If this was to be done properly the rice fields which were the main source of food throughout a great part of India would have to be abolished Were the population to starve in the meantime? Famine had been quite bad enough in recent years without the abolition of the rice fields The best remedies were the freer use of quinine and the segregation of infected individuals The former seemed to be the more practical but the segregation of infected natives would be as difficult a task as the wholesale slaughter of the anopheles

Dr GEORGE A WILLIAMSON (Larnaca, Cyprus) read some Notes on Cyprus Fever He commenced by calling attention to the unscientific system of giving the names of localities to diseases which although doubtless found elsewhere occurred in those localities He went on to state that there was no particular form of fever which belonged to Cyprus alone and which could therefore with any truth be called less frequently met with than in former days. He gave tables showing the proportion of cases of malarial fever of different kinds to each other and of these cases to the whole number of diseases coming under notice in a given time, which indicated that Cyprus was far from being the fever-stricken place it was sometimes supposed to be.

Dr. GEORGE C. LOW (Barbados) gave the results of his Investigations in Malaria and Filaria in Barbados. He found neither anopheles nor malaria in Barbados; but found the culex mosquito and filarial diseases in plenty. He believed that filarial ailments and filariasis could be readily exterminated in Barbados by destroying the breeding-places of the culicidæ. The water-supply of the island was excellent, water being laid on in pipes to the houses, and the culex mosquitoes found their breeding-grounds in the rain-water tanks and pools around the dwellings. Were these tanks covered or done away with and the pools drained the filarial scourge would speedily, in his opinion, be mitigated or altogether wiped out.

Professor R. W. BOYCE (Liverpool) upheld a point contended for in Sir W. MacGregor's paper—namely, that measures adopted in West Africa to eradicate malaria must be adopted for natives as well as for Europeans. He believed that segregation would not be productive of so much good as the extirpation of mosquitoes bearing malarial infection.

Dr. EDWARD HENDERSON (London), although he regarded the method of exterminating mosquitoes as almost hopeless throughout the length and breadth of China, still believed that the example set by Europeans of the several methods of preventing malarial fever would produce a good effect amongst the Chinese and might stimulate many of them to follow the example.

Dr. P. MANSON, F.R.S. (London), held that different methods of dealing with malaria were applicable according to environment. In one place the administration of quinine was alone possible; in another the destruction of mosquito breeding-grounds; and in a third the protection afforded by mosquito netting. In some places all these plans of protection might be expedient, but it was unwise to depreciate one at the expense of the other, or to think that the amelioration even of malarial ailments was not to be aimed at, and he objected to any plan of defeating malaria being condemned merely because it was not completely perfect. It seemed impossible to compel negroes to take quinine, and the attempt about to be made by the Germans in this direction was bound to fail. Dr. Young referred in his paper to the culex larvæ consuming anopheles larvæ when placed in the same pool. When food was scarce this no doubt occurred, but when food was plentiful the two varieties of mosquitoes would be found living side by side amicably. Questions which it seemed expedient to go into were, why was malaria absent and why present in some parts of the tropics? why were anopheles met with in one place and culex mosquitoes in another? and yet again, why were they found both abundant in some places? Could these points be ascertained they would be approaching a rational solution of the mosquito difficulty, and be able to apply "natural" means of exterminating mosquitoes in the place of the present empiric plans by netting, quinine, and destruction of larvæ. They had examples of analogous methods of dealing with parasitic diseases afforded in the cases of the vines in France and of the orange trees in America and he believed that in the future means of prevention would be found in this direction.

Lieutenant-Colonel J. L. POYNDER, I.M.S., considered it impossible to teach the natives of India the use of preventive measures against either malaria or cholera.

Mr. CANTLIE said that the "Swatow lamp" in use in China and the Straits as a means of killing mosquitoes within a mosquito-net was a safe and sure method and that he had had the lamp made in London where it could now be obtained.

Dr. F. M. SANDWITH (Cairo) read a note on

The Entrance of Ankylostoma Embryos into the Human Body by Means of the Skin.

He affirmed that it had long been known that ankylostomiasis infection could occur by the mouth, but the present paper was to draw attention to Dr. Looss's discovery that the embryos had also the power of entering the skin chiefly by the hair follicles. In 1898 Dr. Looss announced this fact, but as there was no analogy for a parasite behaving in this way his paper met with no reception beyond a little hostile criticism. Like many scientific discoveries this was the result of a pure accident. While working in the laboratory of the Cairo medical school a drop of a pure culture of embryos fell on his hand; he happened to examine the drop some minutes later and was astonished to find that it contained countless *empty* embryo sheaths and a few sluggish embryos. The bulk of the embryos had apparently entered the skin. His hand became red and burning and he found himself later suffering from anæmia and debility with evidence of ankylostoma infection in the fæces requiring a prolonged course of treatment. Since then a similar experiment had been made on a human leg one hour before amputation. Sections of the skin showed that the embryos had entered chiefly by the hair follicles. Inside the follicle the embryos pushed their way towards the hair papillæ, during which process, if there were many in the hair follicle, the root sheath of the hair was almost completely destroyed. When the papillæ were reached the embryos left the hair follicle to pierce the surrounding tissue of the true skin.[1] A section under the microscope and some micro-photographs showed many embryos in different stages of entry. It was assumed that the embryo found its way from the skin to the small intestine, but of this there was as yet no proof. Dr. Looss's researches threw an additional light upon ankylostomiasis infection in many countries, and might lead to an analogous discovery with regard to bilharzia and perhaps other parasites.

Lieutenant-Colonel G. M. J. GILES, I.M.S., said that he had seen Dr. Looss's specimens in Cairo, and he quite agreed with his conclusions. He believed that the ova of the ankylostoma gained access to the body by the mouth, being conveyed on the dirty hands of coolies. The earth in Assam tea-gardens teemed with the ova, and as the coolie ate his food with unwashed hands he became infected with the parasite. He was, prepared, however, to agree that embryo worms could gain access by the skin, but he failed to understand how they could reach the intestines in the numbers they did unless they were swallowed.

Dr. MANSON deprecated premature conclusions being arrived at from the discovery of Dr. Looss. He looked upon specimens showing the embryos entering a hair follicle of the skin and thereby gaining access to the subcutaneous tissues more or less in the nature of a curiosity. Were the embryos of ankylostoma placed on the skin he believed they would seek shelter in a hair follicle, but he could not believe that this mode of infection was usual. He suggested further experimental research on the subject.

Lieutenant-Colonel ANDREW DUNCAN, I.M.S. (retired), read a paper on

The Causation of Enteric Fever in India,

in which he reviewed the various theories appertaining to the etiology of enteric fever. He mentioned the vicarious theory of Martin; the transformation theory of M. Colin, who held that fever primarily paludal could be transformed into enteric; the non-specific theory of Moore; the fæcal-poisoning theory of Fayrer; the climatic theory of Bryden; the opinion of Gordon that there was no such disease as enteric fever in India; and the theory of Home who regarded all diseases in which ulcers were met with in the intestine as enteric. Lieutenant-Colonel Duncan said that the factors concerned in the evolution of enteric fever in India were to be found in the facts: (1) the yearly advent in India of a large body of subjects at an age most liable to the disease; and (2) the country presented an environment to these subjects most favourable to the disease. Soldiers in India imbibed the liquids offered for sale in the native bazaars, and in spite of precautions within their barracks became thus infected and also by the dust conveyed by the winds and by the agency of flies. He upheld the inoculations of Professor Wright against enteric fever as being of great practical value.

Lieutenant-Colonel A. CROMBIE, I.M.S. (retired), stated that enteric fever in India was not commonly met with amongst natives. Ghoorkas were liable to the disease; but in Madras and in Lower Bengal enteric ulcerations were not found. He stated that he tested the blood of six natives of India in London and found that three gave Widal's reaction. All these were under 30 years of age and the three in which the reaction was negative were over 40 years of age. A continued fever lasting 21 days was common in India, in which there was no eruption, diarrhœa, or enlargement of the spleen. 75 per cent. of the cases of continued fever in South Africa during the Boer war gave Widal's reaction Concerning the efficacy of Professor Wright's serum for enteric fever, Lieutenant-Colonel Crombie stated that of 300 patients convalescent from enteric fever whom he had seen, 60 per cent. had been inoculated once and 10 per cent. twice Second attacks of enteric fever also had not infrequently occurred

---

[1] Centralblatt fur Bakteriologie, May 31st and July 5th, 1901.

Captain W R. BATTYE, I M S, believed that a benign bacillus could, according to environment, become pathogenic in its properties

Lieutenant Colonel POYNDER, I M S, believed that the immunity of adults in India to typhoid fever was in all probability due to their having had typhoid fever in their youth

Dr SANDWITH said that of course Professor Wright's method of preventing typhoid fever was as yet only on its trial He had seen several cases of enteric fever amongst nurses who had been inoculated He advocated blood examinations after inoculation to elucidate the effects of the anti typhoid treatment

Major F P MAYNARD, I M S, read a paper on

Some Ophthalmic Complications of Plague

He called attention to the injected condition of the eyes which had been described by writers as characteristic of the plague facies, and discussed 12 cases of plague with ophthalmic complications which came under his notice during a recent severe epidemic of the disease at Patna The plague symptoms in all the cases were, or had been severe, but none of the patients died, six recovered with one eye sound, of the remaining 18 eyes vision was lost in five partly lost in eight, and fairly good in five The lesions were for the most part the results of iritis and opacity of media apparently from interference with the nutrition of the eye Tension was diminished in 12 eyes and was normal in the rest It was remarkable that, considering the frequent cases in which blood extravasations in various places throughout the body were met with in plague post mortem examinations, in only one case did a fundus show hæmorrhage Treatment, except in one case, was of no avail because it was started too late

THE PATHOLOGICAL MUSEUM

Relegated to one little room in a corner of the palatial edifice known as the "Winter Garden" the rest of which was devoted to the exhibition of drugs and foods the Pathological Museum can hardly be said to have received its due share of space certainly not commensurate with its importance Perhaps it was a sign of the times

Among the most interesting exhibits may be mentioned a valuable series of photographs illustrating the various lesions met with in the recent epidemic of arsenical poisoning among beer drinkers contributed to the collection by Dr J N Kelynack (Manchester) This included excellent photographs of cases of atrophy of the lower extremities, general wasting double wrist-drop and dropped hands and feet,, and among the skin affections, erythema with keratosis and pigmentation of the palms and soles, general pigmentation with characteristic distribution over the thigh and abdomen extensive scaly eruption, melanosis of the arms and abdomen in a patient whose suckling infant, aged nine weeks also presented symptoms of arsenical poisoning, and a case of ridges on the nails A series of x ray photographs was contributed by Mr J Hall Edwards (Birmingham) who was with the Imperial Yeomanry in South Africa, which included representations of bullets in various positions Here again we find undoubted evidence of the use of soft nosed or expansive bullets by the Boers The same exhibitor showed a portable coil and apparatus for taking radiographs in the field

A series of interesting photographs by Dr E A Dent (Cheltenham) showed various arthritic affections and malformations of the hands. Some beautiful and life like sketches from the museum of St George's Hospital made by Joseph Perry in 1836 illustrated cases of pemphigus and Pott's disease of the vertebra. Upon the same table, placed there presumably for lack of space certainly not for any reason of scientific classification was a very remarkable series of ancient Egyptian bones, exhibiting various forms of fracture These were stated to have belonged to a people living over 2000 years ago and reveal the fact that they were subject to much the same form of injury as those who live in the present day They were presented by Professor D MacAlister to the museum of the Cambridge University and were exhibited by Mr Joseph Griffiths

So cramped was the space afforded that even the side posts of the doorway had to be pressed into the service and here there were suspended two interesting photographs showing a somewhat unusual form of bromide eruption in an infant who had had one of the numerous patent "soothing medicines administered to it and a case of accidental vaccination of chapped hands in a nurse whose parents had refused to have her vaccinated previously on account of ' conscientious objections "

Among the rarer and more interesting of the mounted specimens, mostly prepared by means of the formalin method were the following A ball thrombus in the auricle (from University College Sheffield) from a patient who died with signs of mitral disease and many emboli, the thrombus being loose in the auricle as seen in the specimen. Syphilitic myocarditis (from University College Sheffield) from a man *who was discharged from the army on account of epilepsy,* who died in a fit the muscular substance of the heart showed the mottling It would have been interesting in this specimen to have learned if there were any gross changes in the brain to account for the fits or whether these were as some maintain due entirely to circulatory disturbance Brown atrophy of the heart (from the Royal Free Hospital) from a case of phthisis Thrombus in the thoracic aorta (from Westminster Hospital) the transverse part of the aortic arch and a portion of the descending aorta showed the presence of a firm clot in the lumen of the vessel The clot reached down to the level of the diaphragm It was taken from a body of a man 49 years of age, who died from a large mixed cell sarcoma of the os innominatum There was no evidence found at the necropsy of a collateral circulation Microscopically the clot in the aorta was mostly fibrin but there were a few large cells of sarcomatous appearance in places Specimen of dilated stomach produced by simple hypertrophy of the pyloric sphincter consequent on traction of a moveable kidney (exhibited by Dr H Bramwell Cheltenham) Lymphangiectasis of the intestine (from the Westminster Hospital Museum) The mucosa of the duodenum and commencement of the jejunum was covered with closely-set villous processes which gave it a shaggy appearance In the recent condition the mucous membrane was much congested though the villous projections were white The entire intestinal tract was similarly affected It was taken from the body of a man aged 38 years who had suffered for some months from intermittent attacks of diarrhœa and vomiting Emaciation ensued and he died from exhaustion With the exception of the intestinal condition, which affected the whole of the small intestines, the viscera were normal Specimens of scurvy rickets (from the Westminster Hospital Museum) showing the pelvis and lower extremities of a child who died from the disease The periosteum of the femur was stripped up from the shaft and underneath it was a blood-clot The upper epiphysis was separated and there was a fracture at the lower end just above the epiphyseal line; blood clot intervened between the broken ends The changes were remarkably symmetrical on the two sides The bones of the legs were very soft and could easily be cut with a knife The specimens were from a male child, aged 11 months The child was quite well until the age of five months when he began to fail in strength and general health The child sweated about the head was constantly sick, and very constipated *Red sand was often found in* the urine which was much increased in quantity Two months before admission the mouth and gums became spongy and livid and there was epistaxis Five weeks before death the ankles feet shoulders legs and wrists were swollen and painful and the eyelids and face were puffy

In the department of Comparative Pathology Dr S T Pruen (Cheltenham) exhibited an interesting series of specimens (macroscopic and microscopic) of tuberculosis in birds and animals As an illustration of careful observation and description the microscopic specimens of parakeratosis variegata exhibited by Dr J M H Macleod (London) may be mentioned In general terms the descriptive catalogue had been prepared with unusual care and completeness and the various preparations were well arranged Much credit in this respect is due to Mrs Grace Stewart Billings M B (Cheltenham) the secretary of the Pathological Museum and it is greatly to be regretted that the want of space at her disposal did not enable her to do greater justice to her task.

THE ANNUAL MUSEUM.

(Continued from page 408.)

III.—SANITARY APPLIANCES, DISINFECTANTS, &c.

A quite distinct falling off in the number of sanitary exhibits was notable this year. There were scarcely any constructional sanitary appliances at all, this section being devoted for the most part to the display of disinfectants and antiseptics. Perhaps the most comprehensive assortment of disinfectants and antiseptics was shown by the Sanitas Co., Limited, of Bethnal Green, London, E. Besides a great number of preparations, including soaps, powders, and fluids, the basis of which is the well-known sanitas, many convenient appliances for aerial disinfection were shown. Amongst these may be mentioned the sulphur fumigating candles, giving a definite amount of sulphurous acid gas, the formic air purifier, and the formic sulphugator, evolving sulphurous acid gas in association with formaldehyde. A curious association is sanitas with formaldehyde and known as "formitas." Since sanitas is antiseptic and disinfectant by virtue of its oxidising properties it is difficult to see how it can be associated with advantage with a rapidly reducing agent like formaldehyde. The exhibit included an ingenious drain-tester and disinfectant fluids other than sanitas. Izal is now well known as a convenient and non-corrosive disinfectant fluid. It is prepared in many forms, notably as medical izal for medical and surgical use, as disinfectant powder, as soap, as lozenges, as "perles" for internal administration, and as lint, wool, and gauze. These exhibits were shown by Messrs. Newton Chambers and Co., Thorncliffe, Sheffield. The Ronuk Co., Limited, of 83, Upper Thames-street, London, E.C., showed specimens of wood treated with their preparations, amongst which were illustrations of the sanitary application of ronuk to the floors of hospital wards. The preparation produces an excellent polish and is undoubtedly a sanitary adjunct. Messrs. J. Defries and Sons of 147, Houndsditch, London, E., exhibited the principal forms of the Pasteur-Chamberland filter. The exhibit included also Scurfield's ventilation indicator, an apparatus for the rapid estimation of carbonic-acid gas, the equifex portable sprayers, and illustrations of the equifex disinfectors used in London, Bombay, Calcutta, and elsewhere. The Sanitary and Economic Association of Gloucester showed two ingenious appliances, both of which are the invention of a medical man. The first was a gas-stove designed to effect ventilation and at the same time not itself to contaminate the air, the second was a refrigerator and ice-storer. The Sanitary Wood-Wool Co., of 26, Thavies-inn, Holborn-circus, London, E.C., devoted the space allotted to them to the exhibition of Hartmann's patent wood-wool preparations. These included sanitary wood-wool sheets, vaccination pads, antiseptic sponges, napkins, and gonorrhœa bags. In addition to these were specimens of Hartmann's catgut, and the simplicity and convenience of Hartmann's patent arm-sling already noticed in our columns were demonstrated. The Petanelle preparations were exhibited by Messrs. Paté, Burke, and Co. of 6, Wool Exchange, Basinghall-street, London, E.C. Petanelle is a preparation of fibrous peat which is described as a natural antiseptic and deodorant; its absorbing power is remarkable and on this account it makes excellent material for surgical dressings and pads. It is also employed for accouchement-sheets, hygienic clothing, and for bedding. We have already described petanelle disinfecting powder and fluid, while petanelle foot powder is well worth mentioning in connexion with its application to the feet during excessive perspiration. The Shell brand floor-polish was exhibited by Messrs. A. H. Hamilton and Co., of 106, Elliot-street, Glasgow. This polish, it is stated, is made with pure American turpentine amongst other things, and on account of its sanitary properties is held to be particularly well adapted for the polishing of floors of hospital wards, asylums, and convalescent homes. The exhibit of the Jeyes' Sanitary Compounds Co., of 64, Cannon-street, London, E.C., differed little from their exhibit of previous years. It comprised the creolin preparations, soaps, plasters, capsules, gauze, fluids, powders, and a dentifrice.

IV.—SURGICAL INSTRUMENTS AND APPLIANCES.

There was a distinct variety of surgical appliances shown, comprising surgical instruments, x-ray apparatus, hospital outfits, operation equipments.
Messrs. Meyer and Meltze
London, W., had a
exhibition of

the tincture of strop
that strophanthus
peutically because p
been used. Messrs. [illegible] -street,
London, W., showed a [illegible] of special interest
to surgeons. These included their special operating-table, sterilisers, cabinets for instruments, aspirators, syringes, laryngoscopes, ligatures, and every conceivable aid to surgical work. Patent appliances for the lame were the chief feature of the O'Connor Extension Co., of 2, Bloomsbury-street, London, W.C. Most of these have already been described in our columns. The O'Connor appliance is an ingenious arrangement which compensates for shortening of the leg, yet enables ordinary shoes to be worn. Boots for flat-foot and for raising the toe and for paralysis were also shown. Flax and cotton lint adapted for [illegible] surgical use were shown by the Liverpool [illegible] Netherfield-road North, Liverpool. In addition [illegible] bandage absorbent gauze tissue, and surgeons' tow, this company als showed a special material (transpirable) for ordinary clothin which is said to permit of free evaporation and not to become cold and moist even with profuse perspiration. Mr. R. Strang, of Montpellier, Cheltenham, exhibited a very ingenious pillow-holder and bed-rest, while close by Mr. W. F. Woodland, of 24, Dorset-street, Southampton, exhibited a series of improved artificial limbs the feature of which is ball ankle-joints allowing of the automatic accommodation of the foot to the ground and rotation to prevent twisting or running at the point of bearing. The Dowsing system of the treatment of rheumatism, &c., by radiant heat and light was demonstrated by representatives of the company (24, Budge-row, Cannon-street, London, E.C.). Mr. Harry W. Cox of 9, 10, 11, Cursitor-street, Chancery-lane, London, W.C., exhibited all the lates developments of x-ray apparatus, especially in its application to surgery and medicine. The new electrolytic "break" is worthy of mention as giving a perfectly steady glow and very definite shadows or pictures. This firm supplies all the appliances connected with x-ray work, and we have had some experience of the excellence of the apparatus made by this firm. The coils are wound under personal supervision to provide for effectual insulation. A very well-arranged assortment of surgical instruments and appliances was shown by Messrs. Salt and Son of 5, Cherry-street, Birmingham. Messrs. Rosenberg and Co. of 21, Southampton-row, London, W.C., exhibited their portable x-ray outfits besides a historical collection of various x-ray tubes. Messrs. Allen and Hanbury of Plough-court, Lombard-street, London, E.C., showed a number of useful surgical appliances, including aseptic instruments and caddies of surgical dressings and plasters. They showed also a new inhaler for the administration of ether and also one for use with kélène. The exhibit included the convenient and portable ozone apparatus recently described in our columns and a convenient tray for storing labels. A very ingenious automatic bed-rest was shown by the Automatic Bed-rest Co. of 1, Somers-place, Leamington. It consists of a sling and head support adjusted by pulleys attached by means of springs to the foot-frame of the bed. Special hospital bedsteads and an anti-sagging bedstead were the features of the exhibit of Messrs. John and Joseph Taunton, of Belgrave Works, Birmingham. Similar appliances, the Lawson Tait spring bedsteads, were exhibited by Messrs. George

Sons, Limited, of Dominion Works, Birmingham, and by Messrs. S. P. Whitfield and Co., Limited, of Watery lane, Birmingham. Woods patent wire mattress was exhibited by the Longford Wire Co., of Warrington. This mattress, attached to a bedstead six feet by three feet, will carry one ton weight without injury to the mattress or bed. A very interesting sen [illegible] than 30 cases of double [illegible] hown [illegible] limbs [illegible] omerset. Mr. N. Bletchley [illegible] has devoted his attention [illegible] He exhibited a number of boots adapted for various abnormal conditions and deformities.

(To be concluded.)

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD

REPORTS OF MEDICAL OFFICERS OF HEALTH

City of London.—In his report for the three weeks ending July 13th, Dr. W. Collingridge, the newly appointed medical officer of health, tells us that the Corporation of London have decided to adopt the voluntary notification of phthisis and to pay the usual fee of 2*s.* 6*d.* for each case notified. On the receipt of the notification the invaded house will be visited, disinfection will be offered, and a leaflet prepared by the medical officer of health, setting out the precautions to be observed, will be left. Turning to another matter we are pleased to see that a detailed inspection of the sanitary conveniences at the several railway stations, both above and below ground, has been made in the City, and defects have been found at a very large number of them. This is a very useful public service and it is to be hoped that other medical officers of health will follow this example. Our own experiences over many of the lines of England enable us to urge the necessity of this step.

Surrey County District.—The Surrey County Council have under the advice of Dr. T. O. Seaton, their medical officer of health, taken an active and useful part with regard to the water supplied in the county during 1900. More particularly was this the case with respect to the West Surrey Water Company, the water supplied by which had been the subject of complaint by two urban district councils whose districts were supplied by the said company. Briefly stated, the chemical analysis gave, in the view of these two councils, unsatisfactory results. The company in question has an intake from the Thames a short distance above Walton Bridge and the area of supply is very extensive. Near the intake there are filters but no subsidence reservoirs, the water being delivered direct to the filter beds. The filtered water is pumped to a service reservoir on St. George's Hill. The analyses made by the experts of the company were in favour of the company; those made by the Jenner Institute of Preventive Medicine were unsatisfactory. Doubtless, as Dr. Seaton suggests, the conditions of collection varied, but at the same time the strength of a chain is measured by the resistance of its weakest link. Having regard to these discrepancies Dr. Seaton, who received the assistance of the company in his inquiries, procured a sample before filtration and a sample after filtration, seeking by this means to ascertain whether the filtered water gave average results which are satisfactory at all times and under all conditions of the river. The water was also examined bacteriologically and for this purpose 50 samples were taken. The results of this bacteriological examination were, we are told, satisfactory, but on the other hand the chemical results were unsatisfactory. It is not clear if the filtrate of each filter was submitted to examination or whether there are automatic arrangements for checking the rate of filtration of each filter. But in the meantime the company applied for Parliamentary powers to construct subsidence reservoirs and the county council were able finally to arrange terms upon which alone their opposition to the Bill would be withheld. It may therefore be said that the Surrey County Council have here performed a useful service. Other action has also been taken by this county council in reference to another water company.

Coventry Urban District.—By the provisions of the Coventry Corporation Act, 1900, power has been procured by which the corporation, having erected an abattoir, may revoke, cancel, or call in any licence granted by them, either before or after the passing of the Act, with regard to private slaughter houses, subject to the condition that compensation to the owner shall be given. Similarly the corporation have power to close any private slaughter house which in their opinion is injurious or dangerous to the public health. It will be interesting to note how these provisions are applied in practice.

Kingston upon Hull Urban District.—Dr. Wright Mason, in reporting upon the cases of small-pox which occurred at Hull during 1900, gives a brief summary of the whole outbreak. There were in all 943 cases notified with 163 deaths. There were removed to hospital 904 cases, and of these 748 were vaccinated and 156 showed "no evidence of vaccination from marks." The fatality-rate of the vaccinated was 10·2 per cent. and that of the unvaccinated was 48·7 per cent. The total fatality-rate was 16·9 per cent. 20 vaccinated children under 10 years of age were attacked, with no deaths, while of the 60 children attacked who showed no evidence of vaccination 27 died—i.e., the fatality-rate was 45 per cent.

Hastings Urban District.—Dr. Scarlyn Wilson refers in his current annual report to the practice of the "inflation," or blowing up, of the connective tissue of young animals, such as calves and lambs, immediately after death. This operation is held to improve the appearance of the meat, and there is no doubt that it imparts a fallacious idea of bulk and perhaps, too, of freshness. In other words, it must be regarded as a questionable practice. Dr. Wilson states that "inflation" is practised on ill-nourished meat by the direct lung power of the slaughterer, and certainly this proceeding should be unhesitatingly condemned. We have ourselves seen inflation by means of a pump. But here is another argument for public slaughter-houses where processes such as this may either be controlled or prohibited.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 33 of the largest English towns 5893 births and 4862 deaths were registered during the week ending August 10th. The annual rate of mortality in these towns, which had risen from 14·8 to 22·4 per 1000 in the six preceding weeks, declined again to 22·1 last week. In London the death-rate was 18·3 per 1000, while it averaged 24·3 in the 32 large provincial towns. The lowest death-rates in these towns were 11·9 in Bristol, 12·0 in Croydon, 12·1 in Wolverhampton, and 14·5 in Plymouth; the highest rates were 32·6 in Sheffield, 33·7 in Sunderland, 34·1 in Salford, and 40·6 in Gateshead. The 4862 deaths in these towns last week included 1724 which were referred to the principal zymotic diseases, against 1508 and 1755 in the two preceding weeks; of these, 1436 resulted from diarrhœal diseases, 93 from measles, 71 from diphtheria, 57 from whooping-cough, 34 from "fever" (principally enteric), 27 from scarlet fever, and one from small-pox. The lowest death-rates from these diseases were recorded in Bristol, Cardiff, Swansea, and Halifax, and the highest rates in West Ham, Salford, Leeds, Sheffield, Sunderland, and Gateshead. The greatest proportional mortality from measles occurred in West Ham, Birmingham, Salford, Leeds, and Sheffield; from whooping-cough in Sunderland; and from diarrhœal diseases in Portsmouth, Manchester, Salford, Sheffield, Sunderland, and Gateshead. The 71 deaths from diphtheria included 24 in London, seven in West Ham, seven in Leeds, six in Brighton, and four in Leicester. One fatal case of small-pox was registered in London, but not one in any other of the 33 large towns. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 14, 11, and 13 at the end of the three preceding weeks, had declined again to 11 on Saturday, August 10th; three new cases were admitted during the week, against five, two, and four in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 3148, against 2907, 2974, and 3001 on the three preceding Saturdays; 306 new cases were admitted during the week, against 371, 374, and 391 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 135, 134, and 126 in the three preceding weeks, rose again to 127 last week, but were 38 below the corrected average. The causes of 47, or 1·0 per cent., of the deaths in the 33 towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Cardiff, Nottingham, and in 13 other smaller towns; the largest proportions of uncertified deaths were registered in Blackburn, Sheffield, Hull, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·8 and 19·8 per 1000 in the two preceding weeks, declined again to 19·2 during the week ending August 10th, and was 2·9 per 1000 below the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 13·5 in Aberdeen and 15·0 in Paisley to 20·8 in Glasgow and 30·0 in Perth. The 613 deaths in these towns included 129 from diarrhœa, 13 from measles, 12 from whooping-cough, six from "fever," five from diphtheria, and three from scarlet fever. In all, 168 deaths resulted from these principal zymotic diseases last week, against 101, 134, and 174 in the three preceding weeks. These 168 deaths were equal to an annual rate of 5·3 per 1000, which was 2·5 per 1000 less than the zymotic death-rate during the same period in the 33 large English towns. The fatal cases of diarrhœa, which had increased from 19 to 128 in the five preceding weeks, further rose last week to 129, of which 77 occurred in Glasgow, 19 in Edinburgh, 10 in Dundee, nine in Leith, five in Greenock, four in Paisley, three in Perth, and two in Aberdeen. The deaths from measles, which had been 24, 16, and 13 in the three preceding weeks, were again 13 last week, and included nine in Glasgow and two in Edinburgh. The fatal cases of whooping-cough, which had been nine and 28 in the two preceding weeks, declined again last week to 12, of which nine were registered in Glasgow and two in Edinburgh. The deaths referred to different forms of "fever," which had been 6, 3, 2, and 2 in the four preceding weeks, rose again to six last week, and included three in Dundee and two in Glasgow. The fatal cases of diphtheria, which had been two and one in the two preceding weeks, increased last week to five, of which three occurred in Edinburgh. The deaths from scarlet fever, which had been six and two in the two preceding weeks, rose again to three last week, and included two in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 56 and 65 in the two preceding weeks, declined again last week to 44, and were 8 below the number in the corresponding period of last year. The causes of 23, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·6 per 1000 in each of the two preceding weeks, increased to 22·4 per 1000 during the week ending August 10th. During the past four weeks the death-rate has averaged 20·5 per 1000, the rates during the same period being 18·8 in London and 17·8 in Edinburgh. The 161 deaths of persons belonging to Dublin registered during the week under notice showed an excess of 13 over the number in the preceding week, and included 34 which were referred to the principal zymotic diseases, against 18, 26, and 32 in the three preceding weeks; of these 33 resulted from diarrhœa and one from "fever," but not one from either small-pox, measles, scarlet fever, diphtheria, or whooping cough. These 34 deaths were equal to an annual rate of 4·7 per 1000, the zymotic death-rate during the same period being 5·5 in London and 4·4 in Edinburgh. The fatal cases of diarrhœa, which had been four, 14, 20, and 23 in the four preceding weeks, further rose last week to 33. The 161 deaths in Dublin last week included 58 of children under one year of age and 30 of persons aged upwards of 60 years; the deaths of infants showed a considerable increase, while those of elderly persons were slightly below the number in the preceding week. Nine inquest cases and eight deaths from violence were registered; and 53, or more than one-fourth, of the deaths occurred in public institutions. The causes of nine, or nearly 6 per cent., of the deaths in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING JULY, 1901.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the cities and boroughs in the county of London. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 9·6 per 1000 of the population, provisionally estimated at 4,543,757 persons in the middle of the year. In the three preceding months the rates had been 5·2, 8·5, and 8·5 per 1000 respectively. The rates were considerably below the average in Chelsea, Battersea, Wandsworth, Greenwich, and Woolwich, while they showed the largest excess in Fulham, Holborn, Finsbury, City of London, Bethnal Green, Southwark, and Bermondsey. 22 cases of small-pox were notified last month in London; of these, seven belonged to Hackney, five to Wandsworth, three to Hammersmith, two to Paddington, and two to St. Marylebone. Nineteen small-pox patients were admitted into the Metropolitan Asylums hospitals during the month, and 13 remained under treatment on Saturday. August 3rd. The prevalence of scarlet fever showed a slight increase over that recorded in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Holborn, Finsbury, City of London, Bethnal Green, Southwark, and Bermondsey. The Metropolitan Asylums hospitals contained 3026 scarlet fever patients at the end of July, against 1491, 2291, and 2752 at the end of the three preceding months; the weekly admissions averaged 355, against 179, 339, and 343 in the three preceding months. The prevalence of diphtheria shows a further increase upon that recorded in recent months; the greatest proportional prevalence of this disease occurred in Fulham, St. Pancras, Islington, Hackney, Holborn, and Poplar, There were 1332 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of June, against 960, 1101, and 1169 at the end of the three preceding months; the weekly admissions averaged 209, against 117, 160, and 175 in the three preceding months. The prevalence of enteric fever was slightly in excess of that recorded in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Fulham, St. Marylebone, Hackney, Holborn, and the City of London. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 121, 95, and 125 at the end of the three preceding months, further increased to 166 at the end of July; the weekly admissions averaged 29 last month, against 16, 14, and 25 in the three preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, Holborn, Finsbury, City of London, Bethnal Green, and Bermondsey. The 17 notified cases of puerperal fever included five in Islington, two in Kensington, two in Bethnal Green, and two in Wandsworth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in the public institutions of London having been distributed among the various boroughs in which the deceased persons had previously resided. During the five weeks ending August 3rd the deaths of 7013 persons were registered, equal to an annual rate of 16·1 per 1000, against 17·6, 15·4, and 13·4 per 1000 in the three preceding months. The lowest death-rates last month in the various metropolitan boroughs were 9·0 in Hampstead, 10·6 in Stoke Newington, 11·1 in Lewisham, 11·5 in Greenwich, 12·0 in Wandsworth, and 12·2 in Woolwich; the highest rates were 19·1 in St. Pancras, 20·5 in Finsbury and in Southwark, 20·6 in Poplar, 21·4 in Stepney, and 25·0 in Shoreditch. During the five weeks of July, 1527 deaths were referred to the principal zymotic diseases; of these one resulted from small-pox, 236 from measles, 70 from scarlet fever, 137 from diphtheria (including membranous croup), 98 from whooping-cough, 34 from enteric fever, three from simple continued fever, and 948 from diarrhœal diseases. The lowest death-rates from these diseases occurred last month in the City of Westminster, Hampstead, Stoke Newington, the City of London, Wandsworth, and Lewisham; and the highest rates in St. Pancras, Finsbury, Shoreditch,

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JULY, 1901.

* Including membranous croup.

Stepney, Poplar, and Battersea. The fatal case of small-pox was that of a person belongng to Hammersmith. The 236 deaths from measles were slightly below the average number in the corresponding periods of the 10 preceding years; this disease was proportionally most fatal in Finsbury, Shoreditch, Stepney, Poplar, Southwark, and Battersea. The 70 fatal cases of scarlet fever were 15 below the corrected average number; among the various metropolitan boroughs the greatest proportional mortality from this disease occurred in Hammersmith, Finsbury, Southwark, and Bermondsey. The 137 deaths from diphtheria showed a marked decline from the average in the corresponding periods of the 10 preceding years; this disease showed the highest proportional fatality in St. Pancras, Hackney, Finsbury, Shoreditch, Poplar, Bermondsey, and Camberwell. The 98 fatal cases of whooping cough were only about one-half of the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Stepney, Battersea, and Deptford. The 37 deaths referred to "fever" showed a slight decline from the average number in the corresponding periods of the 10 preceding years; the highest "fever" death-rates occurred in Fulham, Hampstead, Islington, Holborn, Bethnal Green, and Woolwich. The 948 deaths from diarrhœal diseases were slightly less than the corrected average number; among the various metropolitan boroughs the greatest proportional mortality from these diseases was recorded in St. Pancras, Hackney, Finsbury, Shoreditch, Poplar, and Battersea. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during July was more than 28 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 177 per 1000. The lowest rates of infant mortality were recorded in Hampstead, Stoke Newington, Holborn, Greenwich, Lewisham, and Woolwich; and the highest rates in St. Pancras, Hackney, Shoreditch, Stepney, Poplar, and Southwark.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

LIEUTENANT-COLONEL R. W. FORD, D S.O., is appointed Deputy Surgeon of Chelsea Hospital. Lieutenant-Colonel G. W. Brazier-Creagh, C.M.G., holds himself in readiness to embark for South Africa at an early date. Major G. J. A. Tuke has been instructed to join at Woolwich for duty. Lieutenant R. F. M. Fawcett and Lieutenant W. L. Steele have left Aldershot for service in South Africa. Surgeon (on probation) J. C. Hastings has joined at Aldershot.

The undermentioned Majors to be Lieutenant-Colonels (dated July 20th, 1901):—Arthur Mercer Davies, Henry William Hubbard, Thomas Edward Noding, John Robert Yourdi, John Chislett Culling, Robert Isaac Dalby Hackett, George Turner Trewman, Henry Halcro Johnston, Edmond Munkhouse Wilson, C.M.G., D.S.O., Edmund John Erskine Risk, William George Birrell, Michael Dundon, Charles William Stanford Magrath, Alfred Vavasour Lane, George Edward Weston, George Harrison Younge, Richard Francis O'Brien, Charles William Thiele, Frederick Peter Nichols, John McLaughlin, Francis Joseph Lambkin, William Lloyd Reade, Henry James Peard, Samuel James Rennie, John Carmichael, George Washington Brazier-Creagh, C.M.G., and Francis Tichborne Wilkinson.

Surgeon-Lieutenant-Colonel Samuel Farrant, West Somerset Regiment of Yeomanry Cavalry, has been appointed to the medical charge of troops at Taunton, vice Lieutenant-Colonel E. H. Joynt, late R.A.M.C., resigned.

VOLUNTEER CORPS.

Artillery: 1st Banff: Surgeon-Lieutenant S. Clark retires under paragraph 111 Volunteer Regulations. Dated August 10th, 1901. *Rifle:* 1st Volunteer Battalion the Prince of Wales's Own (West Yorkshire Regiment): Surgeon-Captain F. Shann to be Surgeon-Major. Dated August 10th, 1901. 2nd Volunteer Battalion the Princess of Wales's Own (Yorkshire Regiment): Surgeon-Captain S. H. Snell resigns his commission. Dated August 10th, 1901. 1st (City of Bristol) Volunteer Battalion the Gloucestershire Regiment: Surgeon-Captain A. W. Prichard to be [illegible] Dated [illegible]st 10th, 1901. 1st Volunteer [illegible] giment: Surgeon-Captain J. [illegible] Dated August 10th, 1901. 2nd Volunteer Battalion the York and Lancaster Regiment: John Power Shine to be Surgeon-Lieutenant. Dated August 10th, 1901. 2nd (Renfrewshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Lieutenant J. B. Stevens to be Surgeon-Captain. Dated August 10th, 1901. 5th Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Lieutenant J. P. Brown to be Surgeon-Captain. Dated August 10th, 1901.

SOUTH AFRICAN WAR NOTES.

The following have been discharged from hospital to duty:—Civil Surgeon Digby Manfold French and Civil Surgeon Thomas Caldwell.

Civil Surgeon C. R. Hodgson is on passage home in the *Avoca*.

DEATHS IN THE SERVICES.

Surgeon-General Charles Richard Francis, I.M.S. (retired), at his residence, Spencer-park, London, S.W., aged 82 years. He at one time was principal and professor of medicine at the Medical College of Calcutta and examiner to the University of Calcutta. Subsequently he became secretary to the surgeon-general with the Government of India, retiring in 1875.

Inspector-General of Hospitals and Fleets, Henry C. Woods, M.V.O. (retired), late of His Majesty's yacht, has been appointed for service at the Admiralty as member of a committee on the pay and promotion of naval medical officers.

Deputy Inspector-General of Hospitals and Fleets John S. Dobbyn has been awarded the Greenwich Hospital Pension of £50 a year.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE following is a list of the grants awarded by the Committee of Distribution of the Metropolitan Hospital Sunday Fund for the year 1901:—

GENERAL HOSPITALS.

Charing Cross Hospital, £1050; French Hospital, £266 13s. 4d.; German Hospital, £441 13s. 4d.; Great Northern Central Hospital, £716 13s. 4d.; Guy's Hospital, £2250; Hampstead Hospital, £200; Italian Hospital, £50; King's College Hospital, £1250; London Hospital, £4500; London Homœopathic Hospital, £458 6s. 8d.; Phillips Memorial Homœopathic Hospital, £29 3s. 4d.; London Temperance Hospital, £666 13s. 4d; Metropolitan Hospital, £616 13s. 4d.; Mildmay Hospital, £225; Miller Hospital and Royal Kent Dispensary, £250; North-West London Hospital, £341 13s. 4d.; Poplar Hospital, £433 6s. 8d.; Queen's Jubilee Hospital, £83 6s. 8d.; Royal Free Hospital, £875; St. George's Hospital, £1937 10s.; SS. John and Elizabeth Hospital, £58 6s. 8d.; St. Mary's Hospital, £2000; St. Thomas's Hospital, £956 13s. 4d.; Seamen's Hospital Society, £1041 13s. 4d.; Middlesex Hospital, £1783 6s. 8d.; Tottenham Hospital, £258 6s. 8d.; University College Hospital, £1133 6s. 8d.; Walthamstow, £70 16s. 8d.; West Ham Hospital, £375; West London Hospital, £600; and Westminster Hospital, £1291 13s. 4d.

CHEST HOSPITALS.

City of London Hospital for Diseases of the Chest, £666 13s. 4d.; *Hospital for Consumption, Brompton, £1583 6s. 8d.*; North London Consumption Hospital, Hampstead, £458 6s. 8d.; Royal Hospital for Diseases of the Chest, City-road, £333 6s. 8d.; and Royal National Hospital for Consumption, Ventnor, £291 13s. 4d.

CHILDREN'S HOSPITALS.

Alexandra Hospital for Hip Disease, W.C., £125; Banstead Surgical Home, £20 16s. 8d.; Barnet Home Hospital, £34 3s. 4d.; Belgrave Hospital for Children, S.W., £100; Cheyne Hospital for Incurable Children, S.W., £83 6s. 8d.; East London Hospital for Children, Shadwell, E., £583 6s. 8d.; Evelina Hospital for Sick Children, Southwark, S.E., £291 13s. 4d.; Home for Incurable Children, Maida-vale, W., £66 13s. 4d.; Home for Sick Children, Sydenham, S.E., £108 6s. 8d.; Hospital for Sick Children, Great Ormond-street, W.C., £833 6s. 8d.; [illegible] Children, Hackney-road, N.E., £291 13s. 4d.; [illegible] for Children, W., £241 13s. 4d.; St. Mary's [illegible] Monica's, Brondesbury, N.W., £87 10s.; Victoria Hospital for Children, King's road, Chelsea, S.W., £433 6s. 8d.; Victoria Home, Margate, £25; and "The Vine," Sevenoaks, £33 6s. 8d.

LYING-IN HOSPITALS.

British Lying-in Hospital, Endell-street, W.C., £33 6s. 8d.; City of London Lying-in Hospital, City-road, E.C., £45 16s. 8d.; Clapham Maternity Hospital, £33 6s. 8d.; East-end Mothers' Home, £75; General Lying-in Hospital, Lambeth, S.E., £35; and Queen Charlotte's Lying-in Hospital, Marylebone-road, W., £333 6s. 8d.

HOSPITALS FOR WOMEN.

Chelsea Hospital for Women, S.W., £341 13s. 4d.; Hospital for Women, Soho-square, W., £208 6s. 8d.; Grosvenor Hospital for Women and Children, Vincent-square, S W., £125; New Hospital for Women Euston road, W.C, £233 6s 8d; Royal Hospital for Children and Women, Lambeth, S E 203 6s 8d, and Samaritan Free Hospital, Lower Seymour-street, W., £433 6s 8d

OTHER SPECIAL HOSPITALS.

Cancer Hospital, Brompton, S W, £500, London Fever Hospital, Islington, N, £583 6s 8d, Gordon Hospital for Fistula, Vauxhall [illegible] S.W. [illegible] St. Mark's Hospital for Fistula, [illegible] or the Diseases of the Heart, [illegible] Lock Hospital, Harrow road, [illegible] Paralysis, and other Diseases [illegible] W, £41 13s. 4d., National [illegible] Epileptic, W C, deferred, [illegible] the Nervous System, £125, [illegible] ray's Inn road, W.C, £100, [illegible] S E, £175; Royal London [illegible] £625, Royal Westminster [illegible] Hospital of London, Leicester [illegible] Dental Hospital, 149, Great Portland-street, W, [illegible]

CONVALESCENT HOSPITALS.

[illegible] W., £533 6s 8d, [illegible] 13s 4d., All [illegible] Ascot Priory [illegible] Convalescent [illegible] Women Con[illegible] Mission Con[illegible] Convalescent Home Dover, [illegible]mouth £25, Convalescent [illegible] Baldwin Brown [illegible]scent Home, Convalescent [illegible] Convalescent [illegible] Female [illegible] Home for [illegible] Home for Work[illegible] 13s 4d.; St. [illegible] Convalescent Hospital, Clewer, £116 13s 4d, St. Andrew's [illegible] Home for [illegible] Joseph's Con[illegible]

COTTAGE HOSPITALS.

[illegible]

INSTITUTIONS.

[illegible] Dying, £208 6s. 8d.

DISPENSARIES.

Battersea Provident Dispensary, £70 16s 8d, Bloomsbury Provident Dispensary, £10, Brixton, &c, Dispensary, £40; Brompton Provident Dispensary, £18 6s 8d, Camberwell Provident Dispensary, £58 6s 8d; Camden Provident Dispensary, £10 16s 8d; Chelsea, Brompton, and Belgrave Dispensary, £33 6s 8d Chelsea Provident Dispensary, £10; City Dispensary, £91 13s. 4d; City of London and East London Dispensary, £18 6s 8d., Clapham General and Provident Dispensary, £20, Deptford Medical Mission, £15; Eastern Dispensary, £33 6s 8d; East Dulwich Provident Dispensary, £76 13s 4d., Farringdon General Dispensary, £36 13s 4d., Finsbury Dispensary, £33 6s. 8d.; Forest Hill Dispensary, £31 13s 4d, Greenwich Provident Dispensary £19 3s 4d, Hackney Provident Dispensary, £9 2s 4d; Hampstead Provident [illegible] Holloway and North Islington Dis[illegible] 13s 4d; Kentish Town Dispensary, £47 16s; [illegible] Dispensary, £31 13s 4d; [illegible] Leman-street Provident [illegible] 10s; London Medical Mission, Endell-street, £83 [illegible] St. George's, Hanover-square [illegible] Wood and Portland Town Provident Dispensary, £5[illegible] 13s 4d., St Marylebone General Dispensary, £25, St. Pancras and Northern Dispensary £25, South Lambeth, Stockwell, and North Brixton Dispensary, £33 6s 8d; Stamford Hill, Stoke Newington, &c, Dispensary, £46 6s 8d; Tower Hamlets Dispensary, £3[illegible] Dispensary £10, Wandsworth Common P[illegible] Provident Dispensary [illegible] Dispensary, £46 13s 4d [illegible] Westminster General Dis[illegible] Dispensary, £19 3s 4d, [illegible]

Correspondence.

"Audi alteram partem."

“WAS LUIGI CORNARO RIGHT?”

To the Editors of THE LANCET.

SIRS,—Mr. E H Van Someren's paper, under the above title, published in THE LANCET of August 10th, is one of great practical interest It emphasises the harmfulness of a dietetic custom which is becoming increasingly prevalent—I refer to the practice of feeding children almost exclusively on soft pappy food Mr. Van Someren says, in effect, that the manifold varieties of indigestion and the long array of evils which follow in their train are chiefly due to defective insalivation; that if food be properly masticated and insalivated it will pass into the stomach involuntarily and in a condition best suited to the requirements of gastric digestion; and that if this habit be persisted in for a few weeks it will be impossible for the individual to swallow food that is imperfectly insalivated owing to the development of a reflex mechanism controlling certain muscles of the mouth and throat, further, that owing to the habit of bolting food in early life the reflex in question fails to be developed. This view carries with it the assumption, which, indeed, cannot be denied, that our ancestors masticated their food more efficiently than we do ours

Now, Sirs, how comes it that the modern human tends to bolt his food from early years? Is it because he is congenitally more prone to do so than were his ancestors? Or are we to suppose that the human has always needed to be educated in efficient mastication and that our ancestors were more thorough and persevering in this respect than we are? On neither of these assumptions can we explain the modern tendency to bolt food This results from the fact that children are fed on soft food which can be readily swallowed without mastication—that we are, in fact, a pap-fed people Under the head of pap we may include all food which can be swallowed with little or no preliminary mastication—such as bread-and-milk, rusks-and-milk, the numerous children's foods prepared with milk, milk puddings, potatoes and gravy, bread soaked in bacon fat, and pounded meat; these, with an occasional biscuit (variety not specified) and a thin slice of bread and butter, constitute, according to an eminent authority on children's diseases, the correct dietary for the young human from the time of weaning till the age of two years, and I am positively dismayed when I think how widely this pernicious system prevails If asked what is the *most important fact* to insist on regarding the feeding of children after the teeth have appeared I should reply—Let their food be of a kind which compels them to masticate adequately, whether they like it or not It is manifestly quite impossible to teach a child at 10 months, or even one much older than this, properly to masticate if we give it pap only

The evils which result from this system of pap-feeding fall under two heads —

1 Those (referred to by Mr Van Someren) connected with the imperfect preparation of food for the stomach Under the present system a crude mess is allowed to flop down into the stomach *without any proper preparation* by the mouth Is there any wonder that a child with a sound digestion is such a rarity? So hugely, indeed, do digestive troubles loom in the pathological life of the child that it were an almost justifiable exaggeration to say that he has but one malady—indigestion. *It has long been an aphorism* with me: keep a child's digestive system healthy and you keep the child healthy and the best way to do this is to discard the use of paps and instead of casting about for the latest marvel in patent foods to give any plain food we like, provided it is of a kind which necessitates thorough mastication.

2. The second class of evils resulting from pap-feeding have reference to the imperfect use of the jaws and associated structures. Owing to this there is defective development of the jaws and their muscles, also of the teeth, tongue, and salivary glands. Let us not forget that every time the muscles of mastication contract the flow of blood and lymph in the structures of the mouth and accessory cavities, *including the naso-pharynx*, is accelerated. Pap-feeding, therefore, implies a sluggish circulation of blood and lymph in these parts. Now, "adenoid" disease is essentially a disease of pap-fed communities. I leave your readers to draw their own conclusions from these facts.

I am, Sirs, yours faithfully,
Wimpole-street, W., August 10th, 1901. HARRY CAMPBELL.

To the Editors of THE LANCET.

SIRS,—The treatise of Ludovico Cornaro, which, as reported in THE LANCET of August 10th, p. 389, was the subject of discussion at a sectional meeting of the British Medical Association, early found an English translator in George Herbert and can be examined in Warne's edition of his works. Amongst the advantages he derived from frugality Cornaro reckons immunity from malaria while serving upon an agricultural survey. "I ...... abode in ...... fenny places two whole months in the heat of summer (which in Italy is very great), receiving not any hurt or inconvenience thereby, so great is the power and efficacy of that temperance which ever accompanied me." Herbert, himself consumptive, died young, but he speaks well of what are indeed the higher pleasures of the table :—

> "Besides the cleanness of sweet abstinence
> Quick thoughts and motions at a small expense,
> A face not fearing light ;
> Whereas in fulness there are sluttish fumes,
> Sour exhalations, and dishonest rheums,
> Revenging the delight."

I am, Sirs, yours faithfully,
Leek, August 13th, 1901. D. A. ALEXANDER.

THE RELATION BETWEEN HUMAN AND BOVINE TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—The papers which have appeared in this week's issue of THE LANCET bearing upon the possibility of infection with tuberculosis through the medium of milk have suggested a brief comment. It is natural that the discovery by laboratory workers of tubercle bacilli in milk should lead them to assume that milk is a frequent source of tuberculosis, and although morbid anatomists have adduced facts from the post-mortem room to show that they consider the danger from contaminated milk to have been over-estimated, few have not been prepared to admit that primary abdominal tuberculosis is a sequence of ingestion of milk containing bacilli of bovine tuberculosis. This conclusion may appear justifiable, yet it has always seemed to me that it leaves out of consideration the fact that if dust containing tubercle bacilli from the human subject is the great infecting medium for the lungs, there is no reason why it should not be the great source of infection of the intestinal tract also. One has only to walk down a back street in a poor neighbourhood and see dirty-faced infants crawling upon dirty floors, putting every object within reach into their mouths, in order to realise in some small measure how vast must be the number of bacilli of human tuberculosis which are swallowed annually by the infant population. A similar lesson may be learnt in the out-patient room. A crying infant may be seen to be comforted by its mother with an indiarubber teat, which no sooner falls on to the dusty floor than it is picked up and thrust unwiped into the infant's mouth again, a proceeding which is no doubt repeated several times during the day. Another method of infection with human tuberculosis also suggests itself. The habit a woman frequently has of putting a spoon with which an infant is being fed into her mouth, in order to taste or estimate the temperature of the food, must often lead to direct transference of tubercle bacilli to the child. Although we may exclude the possibility of infection with bovine tuberculosis there is no difficulty, as we have seen, in explaining the presence of primary abdominal tuberculosis. The wonder is that it does not occur more often.

The occurrence of tuberculosis of the skin in butchers has been used as an argument in favour of the possibility of infection with bovine tuberculosis. Such an occurrence is, however, by no means conclusive. As is well known, this disease may occasionally follow slight local injuries sustained in various occupations. I have seen tuberculosis of the skin result from a puncture by a gardener's fork and from a prick by a splinter of a deal table. As guardians of the public health it is wise that workers in the medical field should consider milk to be a possible source of tuberculous infection until it is proved to be harmless, but as scientists it is necessary that the subject should be viewed from its various aspects. Had the teachings of morbid anatomy been more carefully weighed possibly less stress would have been laid upon the findings of bacteriology.

I am, Sirs, yours faithfully,
Clifton, Bristol, August 6th, 1901. THEODORE FISHER.

To the Editors of THE LANCET.

SIRS,—The importance of the statement made by Professor Koch at the British Congress on Tuberculosis—namely, that cattle are refractory to injections of tubercle bacilli derived from man—is so great that one is justified in recording any facts which have a bearing on the subject and which may help to decide this vital question. In a series of experiments which I have been conducting for several years I had occasion to introduce tubercle bacilli derived from man into the anterior chamber of the eye of a young cow. Though the dose was not a large one, nevertheless tuberculosis resulted and the eye was converted into a large tuberculous mass in which tubercle bacilli were embedded in large numbers. This is only one case, but still it shows that cattle are not perfectly immune to this organism. That susceptible animals can have tubercle bacilli derived from man injected into the circulation or into a cavity where they are exposed to a large surface without producing tuberculosis, whereas a smaller dose introduced into a smaller area may produce the disease, is, in my opinion, possible. The experiments which no doubt are now being undertaken to prove or to condemn Professor Koch's statements will, I believe, elucidate the fact that cattle are not so susceptible to the tubercle derived from man as has hitherto been thought, but that neither are they quite refractory. Other observations made during the series of experiments referred to disagree with several of Professor Koch's statements, but as these are of somewhat secondary importance, and as I hope to embody them in a paper at an early date, I do not feel called upon to enter into them at present. I am, Sirs, yours faithfully,
Glasgow, July 29th, 1901. PETER PATERSON, M.B. Glasg.

HAY FEVER: ITS REMEDY.

To the Editors of THE LANCET.

SIRS,—Those who reside in towns are little cognisant of the abject misery for a few weeks in the early summer of some of those who live in the country, and especially in a grass-growing district as distinguished from the cultivation of crops on arable land, by reason of that ailment which goes by the name of "hay fever." Many, young and old, it quite prostrates ; to others it renders life a burden while it lasts. When the physiological effect of the suprarenal capsules as a contractor of blood-vessels was first mooted I thought that I foresaw its virtue as a remedy for hay fever, though for a long time I was unable to test its action owing to the lack of a stable solution that would "keep" and be always in readiness. When, however, Messrs. Parke, Davis, and Co., with the advice of Dr. Takamine, perfected their solution of adrenal chloride, 1 in 1000, the difficulty was solved, and throughout this season many sufferers have been relieved of their burden to a marked degree.

For those who suffer from sneezing and wheezing a spray of the solution into the nostrils, 1 in 1000, daily—for its effects last many hours—or twice a day, by virtue of its contracting the distended capillaries in the nasal mucous membrane, removes these discomforts completely for a time varying in the individual and in the character of the day. The congested conjunctiva, which occasions so much annoyance by reason of the smarting and itching which prevents the close use of the eyes, is blanched in a few seconds by the application of a solution of 1 in 10,000 once or twice daily as required. The prostration is largely overcome by the administration of quinine internally. The few cases that are not sufficiently relieved by the use of this simple remedy are capable of cure by the galvano-cautery applied to the nasal mucous membrane

I am, Sirs, yours faithfully,

July 31st, 1901. CLEMENT DUKES

"A SIMPLE FORM OF PUMP FOR INFLATING THE ETHER-BAG."

To the Editors of THE LANCET.

SIRS,—One naturally feels some diffidence in commenting upon the remarks of such an able anæsthetist as Mr. Edgar Willett, but I nevertheless feel that his assertion is somewhat too sweeping. To keep the bag adequately filled when the patient is well under the anæsthetic is an easy matter, but in starting the anæsthetic, say ether (without the previous use of nitrous oxide gas), in a nervous patient where the breathing is shallow and somewhat jerky, I consider a mechanical means of filling the bag would be of great service —I am, Sirs, yours faithfully,

FREDERICK W. COLLINGWOOD,
Anæsthetist to the National Dental Hospital.
Wimpole-street, August 1st, 1901

"BRITISH MEDICAL MEN AND GERMAN WATERING-PLACES."

To the Editors of THE LANCET.

SIRS,—I have only just read Dr Bezly Thorne's letter in THE LANCET of July 27th, p 228 I am gratified he thinks most medical men agree with me

With regard to Schott's treatment, although Dr. Thorne has quoted my letter correctly he must have read it carelessly for I cannot believe Dr Thorne can wish the profession to think his opinion is that unsuitable cases are benefited by Schott's treatment. I never ventured an opinion upon suitable cases. I am, Sirs, yours faithfully,

Manchester-square, W., August 9th, 1901 THOMAS DUTTON.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—Dr Archdall Reid seems to challenge the existence of cases of the "inheritance of acquired characters" May I refer him to a very simple case, one which he can test for himself without much expenditure of time? The instance referred to is small and unimportant, but so much the better for the purpose in view, and is described in *Nature* of August 8th, 1901, p 351, under the heading, "Hair on the Digits of Man" There are, I may add, many other phenomena of hair-direction in man and the lower animals which bear a Lamarckian and only a Lamarckian interpretation I am, Sirs, yours faithfully,

Blackheath, August 10th, 1901. WALTER KIDD

"THE COMING ELECTION OF DIRECT REPRESENTATIVES TO THE GENERAL MEDICAL COUNCIL."

To the Editors of THE LANCET.

SIRS,—I do not wish to call in question the accuracy of your reporter in reference to my answer to Dr Brown Ritchie's question at the recent Cheltenham meeting, *re* the possibility of making the attendance of a medical man compulsory in cases of confinement,[1] but his version of my reply differs from what I meant to say. Instead of stating that I had conversed with members of "both Houses" on the subject I intended to say that from conversations with members of "both parties" in the House of Commons I was certain that such legislation would not be entertained Thanking you in anticipation for permitting me to make this correction.—I am, Sirs, yours faithfully,

GEORGE BROWN,
Direct Representative for England and Wales on the General Medical Council
Gibson-square, N., August 13th 1901

---

[1] THE LANCET, August 10th 1901, p 409

THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION AND THE REPORT OF THE CONSTITUTIONAL COMMITTEE.

To the Editors of THE LANCET

SIRS,—The report of the Constitutional Committee was submitted to, and with but slight modification adopted at, the annual meeting at Cheltenham after a brief, rapid, generally excited, and at times angry, debate, conducted with perhaps less of the *suaviter in modo* than of the *fortiter in re* The Association is therefore committed to a radical reform of its principles but little, if anything, short of revolutionary, and although some discussion may possibly be allowed when the consequential new rules and by-laws are submitted for confirmation at a future general meeting the Cheltenham decisions must, I fear, be looked upon as final. *The principal changes effected are*

[illegible] of the total [illegible] the divisions [illegible] raised from [illegible] be fixed by [illegible] for a share [illegible] the total [illegible] the general [illegible] trades' [illegible] of [illegible], *their first-* [illegible] at the same place and time of the year as the general business and the general scientific meetings, and they are invested with most of the powers hitherto enjoyed by the ordinary members in their general meetings. (Clause 16)

As regards the unattached members (1) it is not unlikely that many may resent so compulsory a dictum; and the enhanced cost of membership (2) may likewise lead not a few to reconsider their position in this respect The adoption of the principle of delegation (3) is, however, a very momentous change and its effect upon the numerical strength of the Association may be still more serious Some members, especially those connected with the public services, as the navy, the army, &c, may have scruples regarding the propriety of belonging to a society the objects and methods of which are so closely allied to those of the ordinary trades' unions, since the delegate system is foreign to other scientific and professional bodies It may be expedient, or even necessary, for ordinary trades' unions, because the members of such have, generally, neither the time nor the means, nor perhaps the capacity, for taking part in their general meetings; but the medical profession is, as a whole, a wealthy one, and its members are intellectually well able, individually, to conduct the affairs of an Association such as the British Medical Again, the setting up of a body of delegates or representatives—the terms in this connexion are synonymous—will to a great extent supersede the ordinary annual meeting of members, whilst it will undoubtedly tend to degrade the status of the Central Council In my opinion this body is a superfluous and expensive machine, a cumbrous and complex duplicate, not only quite unnecessary to the requirements of the Association, but its adoption is derogatory to the position of the Association as a learned and professional society, and will tend, I fear, still further to lower its influence with the public.

I thought it very desirable that the principle of delegation should be formally discussed at the Cheltenham meeting An amendment by me to that effect was accepted by the Council and appeared for days on the agenda printed in the Daily Journals, and I was informed by the general secretary that it would come up in the discussion upon resolution No 2, that, namely, "approving generally the principles of the Constitutional Committee's report" Before my motion was reached, however the discussion upon that resolution was abruptly closured, the resolution was put to the meeting at once and it was carried Thus, no opportunity was afforded for discussing a principle which the chairman of the Constitutional Committee Mr Edmund Owen, in his speech proposing the reception of their report, said he thought was the "crux" of the whole matter

I am, Sirs, yours faithfully.

JOHN INCE, M D St And, Major I M S (retired)
Swanley, August 11th 1901

Action for Damages against a Medical Practitioner.

At the Glamorganshire Assizes held on August 5th, before Mr. Justice Grantham, a collier of Merthyr Tydvil sought to recover £60 11*s.* 10*d.* damages from Mr. J. L. W. Ward, J.P., a surgeon of the same town. Evidence showed that the plaintiff whilst at his work sustained a fracture of the left forearm for which he was attended by Mr. Ward. Fibrous union resulted and eventually an operation was performed by Mr. R. Jones of Liverpool. This gentleman in giving evidence stated that there was no negligence on the part of Mr. Ward. The jury interposed before the defence was finished and returned a verdict for the defendant. Judgment was given accordingly with costs.

The Vaccination Act.

From July 1st to Dec. 31st, 1900, 4440 births were registered in the city of Bristol; of these 2292 children were successfully vaccinated, 10 were insusceptible, in 120 cases there were conscientious objections, 511 died unvaccinated, in 180 cases vaccination was medically postponed, 101 removed to other districts, 331 removed to places unknown, and 895 cases were unaccounted for. In the Frome (Somerset) Union for the second six months of 1900, 230 births were registered and 160 of these were successfully vaccinated.

Phthisis in Wiltshire.

The annual report of the medical officer of health of Wiltshire (Mr. J. Tubb-Thomas) which has been recently issued shows that during 1900 285 deaths were attributed to phthisis, 119 of which were registered in urban and 166 in rural districts. 374 deaths were due to consumption and the various forms of tuberculous disease, giving a death-rate of 1·37 per 1000. The deaths from tuberculous diseases were equal to 9·42 per cent. for all causes, the rate for England and Wales for 1899 being 10·4 per cent. The report adds that the voluntary notification of consumption has been adopted in two or three districts in Wiltshire and a number of medical officers have recommended its introduction. Mr. Tubb-Thomas remarks that where voluntary notification was adopted he offered free of all expense to examine sputa for the bacillus tuberculosis from cases notified and to provide suitable outfits. He has already examined between 40 and 50 specimens of sputa.

August 13th.

SCOTLAND.

(From our own Correspondents.)

Glasgow Health Report.

Dr. A. K. Chalmers has just issued a report giving details of the health and vital statistics of the city for the years 1899 and 1900. In the statement of the death-rate figures are given to show that this has undergone a progressive decline from 24·2 per 1000 in 1881–90 to 21·9 in 1891–97 and 20·6 in 1898–1900. The number of infants dying under one year of age in 1899 was 3686, and in 1900 it was 3733, representing a mortality per 1000 born of 152 and 153 respectively. The mortality in this particular class varies widely in different districts of the city, ranging from 1 in 13 born in Hillhead and Pollokshields to 1 in 5 in Gorbals and Cowcaddens. The analysis shows that the infantile death-rate is increasing in the suburban districts, and Dr. Chalmers suggests that the greater tendency to have recourse to artificial feeding as a substitute for natural nursing may possibly be an influence helping to explain this fact. The cases of infectious disease registered during 1899 numbered 17,833, and in 1900 the total was 16,684. The deaths from the principal zymotic diseases in 1899 were 2296, and in 1900 (including seven deaths from plague and one from anthrax) they were 2277. In June, 1899, a patient was admitted to hospital with small-pox; the man had arrived in the city some 12 days previously, having travelled overland from Marseilles. He had sickened two days before admission, the disease was promptly recognised, the patient was at once sent to the hospital, and there were no secondary cases. The account of the small-pox epidemic which commenced in May, 1900, is to be issued as a special report and will present a very different picture from that just defined. The disease was introduced by a seaman in April. Though the man had small-pox in a confluent form no medical man was consulted until the end of the second week, the patient during the interval being confined to bed in a one-apartment house with one and sometimes two lodgers, and receiving visitors who appear to have been frequently of a convivial turn. That was the earliest scene in an epidemic which before the end of the year had sent 397 cases into hospital and had caused 41 deaths, these numbers being much more than doubled before the outbreak was finally checked in the spring of 1901. Some other figures of interest in the report are—6606 cases of measles in 1900, with 461 deaths; 4162 cases of scarlet fever, with 210 deaths; 540 cases of diphtheria, with 125 deaths; 1013 cases of enteric fever, with 158 deaths; and 72 cases of typhus fever, with 17 deaths. The deaths registered as due to phthisis in 1899 were 1383, and the figures for 1900 were 1418. In the chief sanitary inspector's report a full account is given of the measures of visitation, inspection, disinfection, &c., entailed by the outbreaks of plague and small-pox, and it is intimated that if the increasing demands on the department are to be met adequately there must be some additions to the staff and a re-distribution of the sanitary districts of the city.

The Eyesight of School Children.

In the general statement for 1900 recently issued by Mr. A. E. Scougal, M.A., one of His Majesty's chief inspectors for schools in Scotland, attention is drawn to a report on the examination of school children's eyes drawn up by Miss Marion Gilchrist, M.B., C.M. This report deals with the results of an examination of 588 children in two of the schools under the Govan School Board. Miss Gilchrist found that only 55·6 per cent. of the children examined had "full vision," and that of these there were only 21·4 per cent. who could be described as emmetropic, the others being more or less hypermetropic or astigmatic. Of the 44·4 per cent. of the whole who had only "partial vision," 46·3 per cent. had "less than a half of full vision," and that "nearly all" of those with partial vision complained of headaches and pain in the eyes on reading. One of the head masters, after examining the lists of names sent in by Miss Gilchrist, states the following facts: (1) the greater number of the worst cases of defective eyesight are to be found in the lower division of each standard; (2) of the children who have been kept two years in the same standard almost all those were marked "very defective" in eyesight; (3) very defective eyesight means bad spelling, poor reading, and inaccurate arithmetic; and (4) where good spectacles have been fitted there has been marked improvement in the quantity and quality of the work done. On the basis of these facts the inspector draws attention to the faulty incidence of the light which in many schools is calculated to injure the eyesight, or at least to aggravate the disabilities of children suffering from refractive errors.

Caledonian Medical Society.

The annual dinner of this society was held in Glasgow on August 9th, the chair being taken by Dr. Cameron Gillies. The toast of the evening was proposed by Sir Hector Cameron, who described the objects of the society as three in number. In the first place, it was animated by a patriotic desire to maintain and to extend the knowledge of Celtic traditions, both literary and medical; secondly, through the medium of its journal and scientific meetings the society cultivated professional culture and excellence; and thirdly, it promoted good fellowship among its members. In replying to the toast Dr. Gillies gave an account of the steps which had been taken to secure the medical lore of the Highlands from oblivion and stated that the membership of the society had now reached a total of 200. Other speakers included Dr. J. P. Tulloch (Trinidad), Dr. D. C. McVail (Glasgow), and Dr. Russell (Edinburgh).

August 13th.

IRELAND.

(From our own Correspondents.)

The Irish Workhouse Infirmaries.

The duties of the medical officers of the workhouse infirmaries of Ireland have been increased and their responsibilities widened by a recent and amended order of the Local Government Board. It will be remembered that the original order of the Board in reference to the appointment of assistant officers provided that the boards of guardians should appoint all such and so many assistant officers as the Local Government Board should deem necessary. Nineteen of the boards of guardians appealed and in last May the matter came before the judicial committee sitting in Dublin Castle. After receiving the evidence of many authorities including the President of the Royal College of Surgeons in Ireland, Sir Francis Cruise, Sir George O'Farrell, Sir William Thomson, with others, and after a prolonged investigation, during which the Local Government Board proved beyond question the necessity for their interference with the state of things which prevailed in connexion with the nursing in many of the infirmaries, the council stated that they would advise His Excellency that the order as it stood should be disallowed, but that a rule or order making provision for better nursing was required. A new order with that as its chief object has accordingly been issued and is now in force all over Ireland. By it the medical officer is placed in control of the infirmary and nursing staff, the latter being no longer under the supervision of the matron and being subordinate to the master only for general disciplinary control. "The management of the sick wards under the guardians will be in the hands of the medical officer, to whom the guardians should look for the satisfactory condition of their infirmary and hospital."

Belfast Water Commissioners.

Dr. John Barron after a contested election has been elected a member of the Belfast Water Board. The two planks in his election platform were, first that there was no medical man on this important board, and, secondly, that in reference to the epidemic of typhoid fever he considered that it was due to the state of the subsoil, which owing to bad sanitary arrangements is permeated with the germs of the disease which after dry weather get disseminated and so give rise to epidemics of typhoid fever.

Queen's College, Belfast.

From the report of the President of Queen's College, Belfast, for 1900–1901 it appears that there was an increase in the freshmen of 16, the muster being 115, and there was in the total number of students in all faculties, an increase of 12 over the numbers of the previous year. In the medical faculty there was an increase of 12. Reference is made to the honours gained by students and to the college equipment scheme, to which attention has been drawn several times in THE LANCET.

County Armagh Asylum.

At a meeting of the committee of management of this asylum, held on August 12th, a communication was submitted from the Local Government Board auditor stating that he would be glad to know that the members of committee who had been surcharged in respect of luncheons had agreed to pay for same and he requested to be informed when this had been done so that the amounts might be struck off.

The Local Government Board in Ireland.

There can be no doubt that the general feeling in Ireland against the Local Government Board is increasing. That body are anxious that the Bragan and Glasslough dispensary districts in Monaghan should be amalgamated, but the Monaghan Board of Guardians are resisting on the ground especially that the poor may receive proper treatment. At the meeting of the Monaghan Guardians held on August 12th, the following resolution was passed:—

> That we, the Monaghan Board of Guardians, assembled in meeting summoned by special notice to consider the amalgamation of Bragan and Glasslough dispensary districts, desire to record our most emphatic disapproval of the arbitrary action of the Local Government Board in placing an obstacle in the way when all arrangements for a final and satisfactory settlement of the question had been made by the board. As our arrangement had met with the approval of both the people of those districts and Dr. Stewart we can come to no other conclusion but that the Local Government Board (by their letter of the 2nd inst.) desire to coerce this Board into accepting a system which if allowed to continue would end with disaster to the poor of those districts.

A meeting of representatives from all public bodies in Ulster is to be held in Monaghan on Oct. 26th "for the purpose of taking steps to have the powers of the Local Government Board curtailed, so that the efforts of boards of guardians and councils throughout the country can no longer be vetoed by a body of paid servants who were ignorant of the duties which the people's representatives were proud to discharge without fear or reward."

Belfast District Asylums.

On August 12th there were in the Belfast Asylum 708 inmates (337 males and 371 females), at Purdysburn 149 (109 males and 40 females), and at Ballymena annexe 61 (10 males and 51 females), making a grand total of 917 (455 males and 462 females).

Liverpool Port Sanitary Authority.

Dr. William Hanna, an old student of the Belfast Medical School, has been appointed assistant medical officer of the Port of Liverpool. Dr. Hanna, after a brilliant university career, studied at Berlin and at Cambridge, and was three years on plague duty in India, where he was engaged at the Government Research Laboratory, Bombay. He has had a thoroughly practical training in bacteriology and pathology, knowledge of which is so necessary now for public health officers.

August 13th.

PARIS

(FROM OUR OWN CORRESPONDENT.)

The Quarantine Station at Marseilles.

I HAVE already mentioned[1] in a former letter the arrival at Marseilles of a vessel declared to have cases of plague on board. This naturally produced a feeling of alarm which has now completely subsided, and from the reports of the passengers who have undergone quarantine the public are beginning to have a better comprehension of the course of events. In the first place there appears to be a doubt as to whether the disease was really plague. Medical men of the colonial service, thoroughly acquainted with the special bacteriology of the subject, assert that the bacilli found in the patients by the medical officers of the sanitary service were not the real plague bacilli of Yersin. Moreover, it is necessary to remark that the disease attacked only the Arab stokers shipped at Djibouti and did not affect either the Europeans shipped along with them before their isolation or even the Chinese whose special liability to plague is well known. Passing to another aspect of the question the passengers have described with much bitterness the defective accommodation provided for them in the lazaret where they remained for 10 days. The buildings are handsome and large, but the internal arrangements are faulty in many respects. There are only 24 bedrooms and one general dining-room for the use of all classes of passengers. The bedrooms are not kept in good order, which is explained by the fact that there is only one female servant to attend to them. The neglect of cleanliness is the same as in all the hotels of the south of France, first class establishments alone excepted. The supply of medicines is also insufficient; a patient suffering from diarrhœa could only obtain a little bismuth at the end of three days notwithstanding repeated requests. Although the heat was intense the passengers were supplied with ice only once in 10 days. The place would be quite inadequate for the reception of a number of persons or in the event of a serious epidemic, and it is to be hoped that this false alarm will render a service by drawing the attention of the authorities to its defects.

Hospital Ships for Fishermen.

The Société Française des Œuvres de Mer (French Seamen's Aid Society) has had two special steamers built, the *St. François d'Assise* and the *Saint Pierre*, fitted up in accordance with the latest requirements of sanitary science and used as hospital ships and centres of medical aid for the numerous fishermen who go every year either to the Banks of Newfoundland or to Iceland. These two vessels have rendered valuable services to those men who are careless as regards their health although exposed to diseases of every kind and liable to injuries in connexion with their surroundings and their occupation. The *St. François d'Assise*, which went on its first voyage this year, has made three visits to the Banks of Newfoundland and one to the French Shore. It has been able to relieve much suffering, to pick up men lost at sea on floating wreckage, and in one week of June 25 patients from the fishing boats were provided with beds in the hospital on board. The medical officer and the chaplain went on board numerous boats, rendering aid and treating patients; they also gave their services to vessels of other nationalities, as is provided for by the regulations of the society. This vessel carries a disinfecting stove which was capable of completely disinfecting a ship of war on board of which an epidemic of measles had broken out. The *Saint*

---

[1] THE LANCET, July 2[illegible]th, 1901, p. [illegible]

Pierre, which has been on the Iceland station, has had to encounter terrible storms; it is the second vessel of this name sent there by the society, the first having been lost at sea. It is safe and sound up to now, although the weather has been exceptionally bad, for as many as 147 men are reckoned as having perished this year. Apart from this great mortality due to vessels being lost it is ascertained that, thanks to the presence of the *Saint Pierre*, the sanitary conditions of the fishing fleet have this year been better than ever. The medical officer has had to perform numerous small surgical operations, some Icelanders being among the patients. At the places where the vessel puts in it is welcomed by the population and it has even been exempted from harbour dues.

The Hospital at Djibouti.

The announcement of the closing of the hospital at Djibouti has occasioned much regret. It rendered most valuable services to the numerous French ships which call at this port either entering or coming out of the Red Sea. It is true that the hospital was erected as a temporary measure and was not supported by the Government; it owed its existence to a private undertaking for the carrying out of extensive public works and had to be closed because sufficient funds could not be devoted to it; it had only been erected as temporary ambulance premises for the reception of sick workmen. Nevertheless, from its position on the track of steamers bringing home invalids from Madagascar and from the French colonies in Asia it rendered very great services. Since it has been closed patients have died on shipboard in the Red Sea who might probably have been saved if they could have been landed at Djibouti. The entire press, both medical and political, are strongly urging that the Minister for the Colonies should not only re-open the hospital but should create at the place an important sanitary centre such as the circumstances require.

Mosquitoes in Paris.

M. Blanchard has again brought this subject before the Academy of Medicine by reading a valuable report of a commission appointed to inquire into the means of freeing the city from these unwelcome visitors which become more numerous every year during the hot weather. Although the insects of this description found in Paris belong to the genus culex and are not the anopheles which conveys the malaria parasite, it is not unreasonable to suppose that members of the genus culex may transmit some infectious diseases the method of propagation of which is not yet fully explained. Moreover, although the anopheles has not yet been met with, there is no ground for asserting that it may not exist in small numbers unobserved in the predominant mass, or even that it may not come to be acclimatised in Paris some day, since it is known that this kind lives as well in cold countries as in hot. Without a doubt it has recently been found at Chantilly. Three years ago M. Mosny reported a case in point. The patient was a young girl who had never been out of Paris in her life and who was attacked, to all appearance spontaneously, with well-marked malarial symptoms. It was during the mosquito season, and a young soldier from the colonies suffering from intermittent fever had recently come to live in an adjoining portion of the same house. Among the diseases capable of being transmitted by mosquito-bites M. Blanchard enumerated malaria, yellow fever, and filariasis, and he asked if it was not now time to include leprosy in the list. The mode of transmission of this disease has always remained unknown, but numerous facts are in favour of the mosquito hypothesis. Contagion conveyed by mosquito-bites inflicted indoors at night would explain many facts which have hitherto remained incomprehensible, such as the propagation of leprosy in certain families of street-hawkers in Constantinople, families in which Zambaco Pasha has even believed that the disease must be regarded as hereditary, whilst the other inhabitants of the city escape. The circumstance that these people live together in the same neighbourhoods, taking into account also the mosquitoes in the houses, would account for the observed facts better than a hypothetical heredity would. M. Chantemesse upheld the views of M. Blanchard and quoted several illustrative instances. He cited the case of the medical men attending the leper asylum at San Remo who have never contracted leprosy although they are in very close contact with the patients whom they treat by massage of the skin. The explanation given by M. Chantemesse was that the medical men never sleep in the establishment and leave it before night comes on. He also mentioned the case of a young shepherd in the environs of Nice who contracted leprosy from having several times passed the night in a deserted hut which a leper had occupied and in which he had died. He then described the case of a young man who had spent several weeks in a visit to the same part of the country and who became leprous in consequence of relations which he had with a young girl of the place, who was not herself a leper, but there were lepers in her family, and the young man had several times passed the night in her house. The Academy, after hearing M. Blanchard's report, decided to recommend to the Government the prophylactic measures proposed therein. Their principal feature was the getting rid of the stagnant water of which there is so much in Paris, as it is a resort of the mosquitoes when laying their eggs. Of this kind are the sheets of water in the public and private gardens, various pools, the unemptied public water-carts, the reservoirs belonging to manufacturing establishments, &c. The Academy proposes that these reservoirs should be covered over and that the ponds in the public gardens should be supplied with running water; in the event of this latter precaution being impossible a little petroleum should be put on the water every fortnight from the beginning of spring to the end of autumn. Lastly, the water-carts ought to be completely emptied when they return to their yards and should not be refilled until they are going to be used. The water-carts are not to be disregarded in connexion with the breeding of mosquitoes, for the insects find in them the two conditions most favourable for their reproduction—namely, moisture and darkness. In one of these carts as many as 17,000,000 larvæ of mosquitoes have been found.

August 12th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Late Empress Frederick.

THE lamented death of the Empress Frederick recalls the sad days of the long illness of her husband the late Emperor Frederick. Although the nature of the malady to which the Empress succumbed has not been officially announced it is known that she suffered from cancer of the kidney; the medical bulletin issued two days before her death only stated that "the disease had attacked the internal organs." The illness of the Empress dated from about two years ago and is said in a daily paper to have been the sequel of an accident sustained whilst riding. The malignant growth caused severe pain with occasional exacerbations so intense that according to current report the cries of the patient could be heard for some distance. Notwithstanding her weakness she was able to take carriage exercise in the grounds of her residence at Friedrichshof until last spring, when her condition became hopeless. For the past two months morphia was administered freely. The medical attendant of the Empress was Dr. Spielhagen of Cronberg, and Professor Renvers of Berlin came frequently as a consultant. Both of these gentlemen were present at the closing scene and received the thanks of the Imperial family for their devoted services. The death of Her Majesty will be deplored by many charitable institutions which were favoured with her patronage. In Berlin she founded the Victoria House, an institution for the training of nurses and for the supply of trained nurses to hospitals and families; English methods are followed, and during the first year of its existence the nurses received their training in London hospitals until the requisite arrangements could be made in Berlin. Other institutions which owed their origin to the late Empress were the Emperor and Empress Frederick Hospital for Children, the Association for the Promotion of Domestic Hygiene (Verein für Häusliche Gesundheitspflege), and the Association for Providing Country Holidays (Ferien Colonien) for Poor Children. The *Deutsche Medicinische Wochenschrift*, after paying due tribute to the conspicuous merits of the late Empress, observes that it was by a singular fate that both husband and wife suffered from malignant diseases and that neither of them had the opportunity of benefiting by an early operation.

Alleged Discovery of Cancer Organisms.

Professor Schüller, whose preliminary announcement relative to his researches on carcinoma and syphilis has already been mentioned in THE LANCET of May 26th, 1900, p. 1551, recently published a detailed description of his work It will be remembered that Professor Schüller claimed to have discovered characteristic corpuscles in malignant growths They were said to be round or oval, their size being three times that of the red blood corpuscles and their colour being golden-yellow or brownish, they had a refracting light-coloured capsule and a protoplasm of a darker tinge. These objects were found by Professor Schüller in every specimen of sarcoma and carcinoma, he also made cultures, the tissue of the growth itself being used as the culture medium, the cultures appeared as gray droplets consisting of bodies of the nature above described The first communication, which appeared in the *Centralblatt für Bacteriologie* was comparatively little discussed, notwithstanding the great importance of any discovery relating to the etiology of cancer, but Professor Schüller's second contribution caused a great sensation not so much in medical circles as among the general public The subject found its way into the daily newspapers which published articles with such headings as "The Etiology of Carcinoma," &c, interviewers made their appearance and notwithstanding the attitude of reserve maintained by eminent men the public supposed that the question of the etiology of cancer was definitely settled Professor Schüller's discovery has not up to the present time been verified by any other pathologist although the details of the process followed by him are comparatively simple, and Dr Volker of Heidelberg, assistant to Professor Czerny, has recently made a remarkable communication to the *Deutsche Medicinische Wochenschrift* He states that although he has examined numerous specimens of cancer tissue, both fresh and preserved in alcohol, he has failed to find parasites like those described by Professor Schüller, but by accident he at last discovered what these parasites might perhaps be A specimen on being cleared with a drop of oil of bergamot taken from a corked bottle showed the characteristic capsules in great masses, which it turned out were contained in the oil and occurred most abundantly at the bottom of the bottle According to Dr Volker the supposed parasites are in reality cork cells disintegrated by the oil. In a specimen sent to him by Professor Schüller he found that the alleged organisms were to all appearance identical with the cork cells, and he is therefore of opinion that these bodies have nothing to do with cancer, but are derived from an accidental admixture with the oil used in the preparation of the specimen It will be interesting to know what answer Professor Schüller will make

Professor Koch's Views on Tuberculosis

The *Berliner Korrespondenz*, one of the official organs of the Government, in a reference to the British Congress on Tuberculosis states that Professor Koch explained his views a few weeks ago before a commission at the Imperial Health Office, and that it was resolved that the experiments should be continued on some of the larger animals, such as cattle pigs and sheep the expense being borne by the Government Meanwhile, till the experiments are concluded, the official paper goes on to say, the public are advised to continue to sterilise milk by the application of heat and not to relax any of the precautions which have hitherto been recommended

NEW YORK

(FROM OUR OWN CORRESPONDENT.)

Bellevue Hospital

THE scandals which have occurred at Bellevue Hospital during the past year and the publicity given to these in the medical and lay press have had the good effect of drawing the attention of the citizens of New York to the management and construction of its public hospitals and especially to the most important—Bellevue The State Board of Charities at its monthly meeting on July 10th recommended the abandonment of the present Bellevue Hospital buildings and the construction of new and modern buildings. That this recommendation is well warranted by the circumstances of the case will be better appreciated when it is said that the present main building of Bellevue was built 100 years ago for an almshouse The greater portion of the other hospital buildings is inconveniently situated and ill adapted to the work carried on therein. The board adopted the following resolutions —

> Whereas the State Board of Charities having in view the fact that the demands upon Bellevue Hospital are greater than upon any other hospital in this country and its frequent and thorough inspections having convinced the board that the main buildings of the said hospital are too old and ill-adapted to their purposes to be sufficient to meet the proper demands of the service and being also convinced that the only remedy for present conditions is in a new hospital it is therefore resolved that the authorities of the City of New York are hereby urged favourably to consider the subject of a new and modern hospital to take the place of Bellevue as soon as possible It is further resolved that in the opinion of this board the [illegible] satisfactory help may be retained

It has long been notorious that in addition to the antiquity, incongruity, and inconvenience of the buildings constituting Bellevue Hospital, the accommodation is wofully insufficient Last year 25 000 patients were treated in the institution this being 3000 more than in all the other large hospitals combined It is consequently to be hoped that the city authorities may see fit to give ear to and to adopt the recommendations of the State Board of Charities and that a public hospital may be erected more in keeping with the wealth and intelligence of the citizens of New York than the present ramshackle pile known as Bellevue Hospital

Craig Colony for Epileptics

The annual report of this useful institution has just been published and shows that the system suggested by Dr Frederick Peterson has fully answered the anticipations of its founders Dr Frederick Peterson first mentioned the colony system in America in an article which he published in the *New York Medical Record* in 1887 After the appearance of Dr Peterson's article, the State Charities Aid Association took up the matter this example being followed by the State Board of Charities By the aid of this influential backing a Bill was introduced into the legislature of New York State and after some delay it was passed and was signed by the Governor The report for the past year tells of the rapid and satisfactory progress which the colony has made there was an increase of 340 admissions during the year In the same period there were 106 discharges, deaths or transfers to other institutions some of the colonists being insane some of them not fit subjects mentally for the colony The death rate was low A very large number of colonists were improved to the extent that they were able to return to their own homes and to take up some vocation A point of particular interest in the report is the susceptibility to tuberculosis evinced by the inhabitants of the colony Out of 612 colonists there are now 36 patients suffering from tuberculosis The proposal is made to erect perfectly plain wooden houses, a single storey in height, with plenty of glass in them, with large steam heated sun rooms and plenty of ventilation for the effective isolation of those suffering from pulmonary affections It is further proposed that these buildings should be made so plain and inexpensive that in 12 or 15 years or as soon as they become saturated with disease germs they may be destroyed and others may be constructed A complete pathological and chemical laboratory is also to be established and equipped for the purpose of investigating the pathology and etiology of epilepsy The objects for which the colony was founded are stated in the report to be as follows 1 To treat epilepsy by all the best means known to science and to cure the epileptic if possible 2. To be a home always for those who cannot be cured or as long as they require it 3. To educate in a practical useful and simple way all those who seek its benefits so that they may be able to help themselves These results have been already so successfully attained that the *raison d'être* of the colony has been plainly demonstrated.

The Leper Question in the United States

A commission consisting of Surgeon J H White and Assistant Surgeon G Vaughan and Assistant Surgeon M J Rosenau has been working under the direction of the Surgeon General of the Marine Hospital Service since 1899 making an investigation of the extent to which leprosy prevails in America Although the Surgeon General is not yet ready to publish the results of this enumeration sufficient evidence has been collected to point to the existence of at least 1000 cases of leprosy in the United States, mostly among immigrants and enough to warrant strong recommendations for their segregation. It is said that there are 100 cases, probably more, in New Orleans; in New York seven cases have been reported, in San Francisco 15, and in Chicago three. Dr. Albert S. Ashmead of New York takes a much more serious view of the situation and is of the opinion that leprosy is unquestionably spreading in the United States, and that 5000 is a conservative estimate of the number of persons suffering from the disease in the country. It is thought that the commissioners will almost certainly recommend to Congress, in their preliminary report to be published in December, that national lazarettos should be established in several parts of the country. The commissioners, however, take the view that notwithstanding the widespread distribution of leprosy in the United States and the increase of the disease within the past few years, there is but small cause for alarm. They declare themselves convinced that the malady is neither so deadly nor so readily communicated by contagion or infection or association as tuberculosis. Dr. Ashmead, on the other hand, believes that it may be communicated by physical contact. The relative contagiousness of leprosy is, however, still a moot point; that it is so to a certain degree is generally acknowledged and the plan proposed by the United States Commission should, it would seem, act as an effective check to its spread.

August 6th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Outbreak of Small-pox.

THE outbreak of small-pox introduced into the Southern States by the R.M.S. *Ormuz* is gradually declining. The patient who contracted the disease at Perth after boarding the vessel died, as did a passenger from Perth to Adelaide who contracted it on the voyage. A niece of this patient who attended him, although successfully vaccinated, has been severely attacked. There are still 40 people quarantined at Adelaide and these *détenus* are getting up a petition to the Government pointing out what they consider glaring instances of mal-administration on the part of the Health Department. They allege that an inspector of the department was sent to Torrens Island (the quarantine station) to superintend the interment of the fatal case. He returned without taking any precautions against infection, while the officiating clergyman and undertaker had to be disinfected and fumigated. Two of the caterer's employés have been released from quarantine before they had undergone the full period, and although in actual contact with the fatal case; and another person was released on the ground that his mother had suffered from small-pox. Two of the nurses at the Torrens Island quarantine station have contracted the disease. At Melbourne a passenger from Fremantle who was infected on the voyage has died and the body was cremated. In Sydney a quarantined passenger on the *Ormuz* refused several times to be vaccinated and has been attacked by small-pox. Owing to the occurrence of this case 20 days after the last case was reported the Health Department is considering the advisability of detaining the persons still in quarantine for further periods. The practice hitherto has been to allow successfully vaccinated persons to be released at the end of 15 days from the date of the last recorded case, and those unsuccessfully vaccinated, or refusing to undergo the operation, at the expiration of 21 days. In some cases, however, persons coming under the second category have been released at the expiration of 15 days. This will not be permitted in future, and the 50 persons still in quarantine will be kept there for a further term of 21 days. A patient who contracted small-pox in Sydney has died. The Health Department of New South Wales report having satisfactorily established the connexion between the cases that arrived by the s.s. *Chingta* and those which occurred at North Sydney, thus removing the fear that the disease had got an independent hold in the city. In Queensland no cases have occurred and a proclamation has been issued directing persons crossing the border to undergo examination by the health officer and to furnish their names and addresses.

The Plague.

Two further cases of plague—one fatal—have occurred in Brisbane. It is over a month since a case occurred in any of the other states, and the Board of Public Health in Victoria has removed the restrictions on inter-state shipping in connexion with plague. The medical inspection will be dispensed with and the bathing regulations will not be enforced. The restrictions on shipping from plague-infected over-sea ports will be maintained. The Board will continue its policy of rat-destruction.

Plans of the Proposed Hospital for North Sydney.

Competitive designs for the new hospital for North Sydney were invited by the committee and the first premium of £100 has been awarded to Mr. A. E. Shervey. The complete design provides for a hospital containing 200 beds arranged in 13 blocks, with ample accessory accommodation, at a cost of £50,000. It is proposed to erect a portion containing 48 beds for £10,000, including two main wards, on the pavilion plan, each containing 20 beds, two isolation wards, and an infectious ward of four beds, with administration block, operating theatre, and mortuary. The buildings are to be in brick, with stone dressings in Renaissance style, fireproof, and the walls finished with Keen's cement. Ventilation is to be by the Tobin system, with an exhaust fan to carry all vitiated air through ventilators in sanitary towers placed over each building. The pavilions are on an axial line bearing north north-east, so that all sides will have the sun, and are also arranged so as to provide for economy in administration.

Private Hospitals.

Few cities are so amply provided with private hospitals as is Melbourne in proportion to population. There are nearly a dozen in the city itself kept by nurses, while five others are owned and conducted by surgeons themselves exclusively for their own patients. In many of the suburbs also there is a private hospital, generally carried on by a nurse, sometimes by a medical man. The Board of Health has been considering the advisability of regulating these establishments more stringently, and a comprehensive code was recently drawn up, though it has not yet been formally adopted. The regulations refer chiefly to the provision of means of escape in case of fire and the construction of the buildings.

A Second Officer of Health for Sydney.

It has been recommended that a second officer of health should be appointed in Sydney, and it is likely to be carried into effect, and that Dr. F. Stokes, D.P.H., will be appointed. Dr. Stokes is a graduate of Sydney University who has recently returned from England, where he made sanitary science a special study.

The Australian Natives' Association and the Medical Profession in New South Wales.

At the first annual conference of the New South Wales Australian Natives' Association, held in Sydney, a motion was carried to the effect that the various friendly societies should be communicated with and asked to join the association in issuing a circular to Members of Parliament requesting them to support future legislation dealing with the *compulsory* consultation of medical practitioners. This resolution was the outcome of the refusal of the New South Wales branch of the British Medical Association to conform to certain requests of the Australian Natives' Association.

Medical Students' Fees at Melbourne.

At a recent meeting of the Council of the Melbourne University a letter was read from the Medical Students' Society drawing the attention of the Council to the fact that the cost of medical education at the Melbourne University was now £20 more than that at Sydney University, and requesting that it might be diminished. It was pointed out that the increase was due to the action of the committee of the Melbourne Hospital in raising the fees there from £5 5*s*. for the whole course to £5 5*s*. a year. It was finally decided to invite the president of the hospital to join a deputation from the council of the university to the Chief Secretary to see if the matter could not be adjusted.

Peculiar Suicide of a Medical Man.

On June 24th a medical practitioner named Thomas Henry O'Reilly committed suicide in an unusual manner—viz., by opening his femoral artery with the point of a safety-pin and bleeding to death. Dr. O'Reilly had been practising at Huntley, near Christchurch, New Zealand, and then travelled for a time as medical attendant to a patient of unsound mind. He then began to suffer from depression of mind and mental symptoms similar to those of his patient and came to Sydney for the benefit of his health. While staying at the

Metropole Hotel he was found with a rifle pointed at his heart and his toe on the trigger and he voluntarily said that it would be well if he were placed under restraint. He was accordingly taken to the police-station and during the night committed the act mentioned.

Serious Charge against a Medical Man.

On June 14th Frederick William Marshall, a medical practitioner residing in Sydney, was committed for trial on a charge of procuring criminal abortion. He had been attending a girl who was subsequently admitted to the Prince Alfred Hospital with septic peritonitis after an abortion, and who, though she eventually recovered, when in a serious condition made a dying deposition concerning Dr. Marshall and identified him when he was brought to her bedside.

Treatment of Cancer.

In the *Intercolonial Medical Journal* for June is a paper by Mr. J. H. Webb on the Nature and Treatment of Cancer which contains some novel suggestions. He regards cancer as due to chemical changes in glandular secretions which control the proliferation of cells, just as myxœdema is regulated by the thyroid secretion. The gland secretion chiefly at fault in cancer, Mr. Webb maintains, is bile, and the constituent of the bile that is wanting is soap, which holds cholesterin in solution. He therefore advises the use of soap, injected hypodermically near the disease, and also administers thyroid gland extract, which he maintains affects the fibre constituent of cancer as the soap affects the cells.

Antidotes to Cyanide Poisoning.

In the same number of the *Intercolonial Medical Journal* is an interesting communication containing the results of a number of careful experiments conducted at the Physiological Laboratory of the Melbourne University by Dr. C. J. Martin and Mr. R. A. O'Brien, to determine the value of peroxide of hydrogen, chloride of cobalt, and ferrous hydrate as antidotes in poisoning by cyanide of potassium. They conclude that while peroxide of hydrogen completely destroys prussic acid in time it is essentially a slow reaction, and fails for this reason as an antidote, which must act rapidly. Cobalt salts dispose of the prussic acid instantaneously, and in the presence of such amounts of hydrochloric acid as occur in the gastric contents, but the cobalt salts are themselves poisonous, and in order to ensure rapid conversion of potassium cyanide into insoluble cobalt cyanide a considerable excess of cobalt chloride must be taken, enough to produce dangerous or even fatal symptoms. Ferrous salts administered with sufficient alkali are as efficacious as cobalt salts, but possess two disadvantages—the difficulty of keeping them in solution and the absolute necessity of neutralising the acidity of the stomach contents. This can best be effected by the simultaneous administration of magnesium oxide. It is suggested that in mines and places where cyanide is used and opportunities for accidental poisoning occur the necessary antidotes should be kept ready, and the following are recommended: (1) one ounce of 23 per cent. solution of ferrous sulphate; (2) one ounce of 5 per cent. solution of caustic potash, in hermetically sealed tubes, which can be broken into a receptacle; and (3) 30 grains of powdered magnesium oxide, to be added to above in half a pint of water.

July 4th.

Obituary.

RICHARD CHARLES SHETTLE, M.D. ST. AND., M.R.C.S. ENG., L.S.A. LOND.

DR. SHETTLE died at his residence, Carlton Lodge, Nailsworth, Gloucestershire, on July 21st, aged 77 years. He received his medical education at St. George's Hospital and qualified M.R.C.S Eng. in 1846 and L.S.A. in 1847. He then became house surgeon at the Dorset County Hospital, eventually entering into general practice at Donhead, Wiltshire, when he was appointed medical officer to the Tisbury Union; subsequently he removed to Cann, near Shaftesbury, Dorsetshire. In 1858 he obtained the M.D. of St. Andrews University and wishing to relinquish general practice and to devote more time to scientific pursuits he, on the death of Dr. Cowan in 1863, removed to Reading and was appointed physician to the Royal Berkshire Hospital. Subsequently he was appointed medical referee to the National Hospital for Consumption at Ventnor, consulting physician to the Midland Counties Home for Incurables, the Berkshire Friendly Societies, and the Reading Dispensary. He was for some time President of the Reading Pathological Society and besides reading many papers on clinical and pathological subjects before this society contributed papers on the Pathology of Insanity, and Hypnotism, its Nature and its Cause, and whilst conscientiously meeting the claims of patients he experimented much and continuously in the field of electricity and magnetism. His earliest paper, on Electricity as the Principle causing the Vitality and Coagulating Property of the Blood, was written when in general practice and was published in THE LANCET of August 29th (p. 244) and Sept. 12th (p. 304), 1863. From the numerous papers that he published on this subject mention may be made of Experiments showing the Paramagnetic Condition of Arterial Blood as compared with the Diamagnetic Condition of Venous Blood and a New Method of Investigating the Magnetic Lines of Force in Magnets, both being read before the Royal Society and published in its proceedings, and of several letters on the Physiology of Death by Electric Shock, published in THE LANCET of Sept. 14th (p. 694), 28th, (p. 809), and Nov. 23rd (p. 1323), 1895. He also read a paper on the Cattle Murrain before the British Association in 1865. Besides his professional and scientific work he found time for other pursuits and was elected chairman of the Reading School of Science and Art on the death of Dr. Wells, and he took much interest in the founding of the Reading College (of which body he was a governor), contributing liberally to its physical laboratory. He was also a life member of the Victorian Institute and Physical Society of London. He was deeply religious and was highly esteemed by all, and his kind and courteous manner combined with his simple and honourable ways endeared him to all with whom he came into contact. On retiring from practice in 1896 Dr. Shettle was made consulting physician to the Royal Berkshire Hospital, honorary member of the Reading Pathological Society, and was presented by the members of the medical and surgical staff of the hospital at a farewell dinner given by Mr. Oliver Maurice, then senior surgeon, with a pair of silver candlesticks.

He was twice married, and had by his first wife two daughters, one of whom predeceased him; the surviving one is married to the Rev. F. T. Colson, M.A., vicar of St. John's Church, Reading. The funeral took place at Nailsworth, the remains being interred at Amberly. Several people journeyed from Reading to do the last honour and the staff of the hospital sent a wreath. On his death becoming known the flag at the hospital was placed at half mast and remained so until after the funeral.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the First Examination of the Board at the July quarterly meeting of the examiners in the subjects indicated:—

Chemistry.—John Henry Dyke Ackland, St. Thomas's Hospital; [illegible] Mary's Hospital; Hugh Lowrie [illegible] stin, Birmingham [illegible] Institute and St. [illegible] Yorkshire College, [illegible] al; John Holdero, [illegible] ur Bright, Gener [illegible] Ronald Andersen [illegible] ery Chamberlain, Cambridge University [illegible]; Horace Charles Colyer, Birkbeck Institute; Eric Alvis Collins and Reginald Branch Dawson, Guy's Hospital; Walter Emery Davies, Owens College, Manchester; Arthur Hubert Davis, St. George's Hospital; Alexander Collingwood Dickson, Cambridge University, Guy's Hospital and Birkbeck Institute; Edmund Michael Dolan, Yorkshire College, Leeds; William Cope Doughty, University College, London; Herbert James Drake, St. Mary's Hospital; Thomas Hugh Edey, Guy's Hospital and Birkbeck Institute; Archibald Finlay and John Eugene Forman, London Hospital; Stanley Elder Gibbs, St. Thomas's Hospital; James Glenny Gibb, Charles George [illegible] Harvey, St. Bartholomew's H[illegible] versity College, Sheffield; Peter [illegible] Manchester; Thomas Reginald [illegible]

Duke Gwynne Howell, St. Thomas's Hospital; Roderick Jackson, University College, Liverpool; Robert Lecky, University College, Bristol; Alfred Vernon Ledger, Guy's Hospital; James [illegible] St. Mary's Hospital; John Ross Lloyd, [illegible], and William Stewart Nealor, St. Bar[illegible] Brian Bentley Metcalfe and Henry [illegible] Hospital; Clayton Conyers Morrell, University College, Liverpool; Richard Denis Neagle, University College, Cardiff, and St. Mary's Hospital; Henry Sandford Ollerhead, St. Mary's Hospital; Jeffery Wimperis Parker, University College of South Wales, Cardiff; Robert Elliot Pitts, Middlesex Hospital; Horace J. D'Arcy Gerrard Price, Birmingham University; Stanislaus Reader, Stonyhurst College, Staffs; Edward Ebenezer Rendle, Guy's Hospital; Felix Stephens Rood, University College, London; Sidney John Rowntree, Birkbeck Institute; John Walter Lennox Scott and Frank Montague Wilson South, Westminster Hospital; Ernest Henry Shaw, St. Bartholomew's Hospital; Hugh Godwin Sherren, London Hospital; Albert Shepperd and Reginald Willan, Guy's Hospital; Charles Ward, Middlesex Hospital; Arthur Christopher Watkin, University College, Aberystwith; Edmund Stanley Whitcombe, Birmingham University; Francis Hugh Ponghill Willis, St. Mary's Hospital; and James Montagu Wyatt, St. Thomas's Hospital.

Pharmacy.—Leonard Ernest Acomb, University College of South Wales, Cardiff; Hugh William Acton, Middlesex Hospital; James Adler and George Bever, London Hospital; Arthur Keith Armstrong, Richard Charles Palmer Berryman and Rowland Alessandro Bowling, St. Bartholomew's Hospital; Thomas St. John Barry and Lawrence Twemlow Booth, University College, Liverpool; Hugh George William Beckett, St. Mary's Hospital; Samuel Landor Benton and John Henry Douglas Bolton, University College, London; Frank Gower Bergin, University College, Bristol; Frederick John Chanter Blackmore, University College, Sheffield; Frederick Richard Bray and Percy Horace Bryant, private study; Albert John Knowles Brayton, Owens College, Manchester, and University College, Liverpool; Wilfrid Buchanan Burr and Edward Cecil Clements, Middlesex Hospital; Sydney Carter and David Kirkpatrick Coutts, St. Thomas's Hospital; Edward Postle Gwyn Causton, Cambridge University and St. Mary's Hospital; Clifford Pendrill Charles and William Rex Collingridge, St. Bartholomew's Hospital; Cyril Thomas Cheatle, King's College, London; John [illegible] ier and Hugh Rose [illegible] College, London; [illegible] ward John Crew, [illegible] University College, Sheffield; Walter C. O. Cornwallis Davies and Ernest Montefiore De Willon, St. Mary's Hospital; Percival Alfred Dingle, St. Bartholomew's Hospital; Alfred Dinnis, Charing-cross Hospital; Edmund Michael Nolan, Yorkshire College, Leeds; Bernard [illegible] St. Thomas's Hospital; Frank Rowe [illegible], London; George Tatham Davison [illegible] and St. Mary's Hospital; Thomas [illegible] Llewellyn Evans, University College of South Wales, Cardiff; George John Eady, Christopher Elliott, Richard Vernon Favell, Charles Henry Fernie, and William Edward Lindsey Fowler, St. Bartholomew's Hospital; George Edward Fritche, Middlesex Hospital; Charles Frederick Fraser and Arthur William Gater, Guy's Hospital; Lawrence George Gibson, London Hospital; Cecil Irving Graham, St. Mary's Hospital; Henry Edwards Griffiths, University College of South Wales, Cardiff; Hugh Evelyn Gotellee and Langton Fuller Hanbury, St. Thomas's Hospital; James Glenny Gibb, Leonard Gray, John Purser Griffin, and Edward William Dacre Hardy, St. Bartholomew's Hospital; Albert Oliver Macarius Heslop, private study; James Gilkinson Higgins, Glasgow University; Sidney-Ernest Holden and Herbert Vawser Humphry, University College, London; William George Hopkins, St. Mary's Hospital; Adrian Russell Fortescue Hubbard, Charing-cross Hospital; Henry Roscoe Ibbotson, Yorkshire College, Leeds; Harold Jacques, London Hospital; William Warwick James, Middlesex Hospital; Aneurin Ernest Jenkins and Thomas Jones Jenkins, University College of South Wales, Cardiff; Thomas Alfred Killby and Henry John Sullings Kimbell, St. Bartholomew's Hospital; George Johnson Langley, St. Thomas's Hospital; Alan Arthur Hinds Lawrence, Cambridge University and University College, London; Arthur Edward Leapingwell, St. Mary's Hospital; William Sherwood Livock and Arthur Harkness MacDonald, London Hospital; Conrad Loddiges, Walter Gerald Loughborough, James Eustace Radclyffe McDonagh and Reginald Charles Pattison McDonagh, St. Bartholomew's Hospital; Walter St. Claire McClure, University College, Sheffield; Frank Derecourt Martyn, Westminster Hospital; George Body Messenger, University College, Liverpool; John Henry Napper, King's College, London; Reginald Cavan Neil, University College, London; Lionel Edward Close Norbury, St. Thomas's Hospital; Douglas Catterall Leyland Orton, Owens College, Manchester; Jeffery Wimperis Parker and Charles Robert Mower Peaty, University College of South Wales, Cardiff; Richard Meynell Pearson, private study; Henry Mallock Prins, University College, London; Philip Alfred Reckless, University College, Sheffield; Edmund Arthur Roberts, King's College, London; Frederick Emilius Roberts, St. George's Hospital; Ralph Raby and Charles Gibbons Seymour, St. Thomas's Hospital; Arthur George Lawrence Reade, Alexander Alfred Smith, and Thomas Stordy, Charing-cross Hospital; Stuart MacKenzie Saunders, private study; Ernest Henry Shaw, St. Bartholomew's Hospital; Armstrong Smith, Middlesex Hospital; James Herbert Sutcliffe, Yorkshire College, Leeds; Nicholas Tarr, St. Geo[illegible] G[illegible] Stanley Thompson, St. Mary's Hos[illegible] tesau, University College, London; Jose[illegible] and John Ronald Rigden Trist, St. [illegible]; Henry Strawson Turner, Amyas [illegible] and William Wynne Williams, King's College, London; Henry Cecil Waldo, University College, Bristol, and St. Bartholomew's Hospital; Cuthbert Gerald Welch and Arthur George Wells, University College, London; John Arthur West, Cyril Oswald Oxford Williams, Everard Lister Wright, Harold Nairne Wright, and Alexander Chamier Wroughton, St. Bartholomew's Hospital; Charles Wheen and David Wilson, St. Thomas's Hospital; Alfred Gurth Whitaker, Charing-cross Hospital; Merwyn Turberville Whitehouse, Birmingham University; Fielding Charles Whitmore, Guy's Hospital, Bristol, and Dublin; and Archibald Paterson Wright, Glasgow and Charing-cross Hospital.

Elementary Biology.—John Aspinall, London Hospital; Edward James Balchin, and George Herbert Curtis, Birkbeck Institute; George Chaikin, University College, Sheffield; Lawrence Drew Ching and Malcolm Robert Coalbank, St. Bartholomew's Hospital; Bevil Molesworth Collard, London Hospital; Eric Abdy Collins, Guy's Hospital; William Cope Doughty, University College, London; Frans Gustaf Edholm, Birkbeck Institute; Thomas Llewellyn Evans, University College of South Wales, Cardiff; Archibald Finlay, London Hospital; John Vere Foster, Birmingham University; Charles George Grey, St. Bartholomew's Hospital; William Harrison, University College, Sheffield; Robert Grey Gillies and Edgar Joseph, Birkbeck Institute; Maurice Aloysius Kenny, Yorkshire College, Leeds; Edward Westcott King, St. Thomas's Hospital; John Alfred Laughton, Charing-cross Hospital; Septimus Joseph Leo, Middlesex Hospital and City of London College; James Charles Robert Lind, University College, London; Raymondo Gabriel Magliono and John Mellor, Owens College, Manchester; William John May, William Morgan, and Clayton Conyers Morrell, London Hospital; Leonard Alexander Stewart Mutch and Arthur Stanley Piper, Birkbeck Institute; Thomas Norman and Felix William Parfitt, Guy's Hospital; Stanislaus Reader, Stonyhurst College; Leslie Lewis Clayton Reynolds, Epsom College; Harold Trenchard Rossiter and George Alan Simmons, St. Thomas's Hospital; John Walter Lennox Scott, Westminster Hospital; Robert Burslem Sparrow, London Hospital; Maurice Redfearn Smith, George Gilbert Timpson, and William Westland Vaughan, Guy's Hospital; Frank Harold Stephens and Alan Geoffrey Wells, St. Mary's Hospital; Reginald Thane Taylor, Birkbeck Institute; Trewyn Richard Williams, University College; Cardiff; and Albert Blagbrough Wolfenden, Yorkshire College, Leeds.

UNIVERSITY OF EDINBURGH: FACULTY OF MEDICINE.—The following is the official list of passes at the recent First, Second, and Third Professional Examinations:—

First Professional Examination.—Thomas Addis, D. C. Alexander A. C. Alport, K. G. Archer, C. R. M. Baker, George Banks, George S. Banks, D. M. Barker (with distinction), G. G. Bartholomew, Douglas Bell, W. J. E. Bell, J. W. Bingham, Norman Black, D. P. Blair, R. A. Blake, Elizabeth H. Brock, Herbert Brown, J. W. Cairns, J. S. Caldwell, Herbert Cargin, N. S. Carmichael, Marjorie Duake-Cohen, William Collins, B.A., H. P. Cook, F. W. Cragg, J. A. Cruickshank, Irene B. Cunningham, Davidina R. J. Davidson, Thomas Davidson, L. F. Dawson, J. M. Dickson, N. C. Dutt, H. A. Edwards, C. E. Elliston, S. C. Fernando, R. S. Frew, F. H. S. Gardner, Jessie H. Gellatly, D. G. Gray, E. J. C. Groves, J. T. Gunn, George Hadden, J. R. Hall, D. G. Harries, W. M. Hewetson, J. R. Holgate, J. C. Holm, G. H. Howe. Joseph Ings, Annie Jackson, Solomon Kark, J. R. Kerr, J. S. Kinross, Ethel Landon, James Lindsay, J. A. Loughridge, A. S. Macbeth, T. A. MacGibbon, B.Sc., K. W. Mackenzie, Helen W. M'Millan, Stewart M'Naughton, W. J. Maloney (with distinction), S. E. Martin, E. S. Massiah, D. M. Matthieson, M.A., Ada E. Miller, A. I. Miller, Aimee E. Mills, B.Sc., O. M. Mirylees, D. L. Morrison, H. L. Morrow, Harold Mowat, R. E. Moyes, Anna M. Mulholland, E. B. Munro, R. R. Murray, R. E. U. Newman, A. J. R. O'Brien, A. A. Ollivierre, William Patton, D. H. Paul, J. L. Pearce, K. A. O. Quainoo, George Raffan, Mabel L. Ramsay, H. E. Rawlence, W. E. Reynolds, C. S. U. Rippon, H. D. Robb, T. E. Roberts, J. Z. H. Rousseau, W. M. Scott, W. J. B. Selkirk, M.A., J. G. B. Shand, Alice C. Sharp, E. S. Simpson, I. Y. Smail, T. R. Smith, R. A. Spence, Alexander Stephen, M.A., A. D. Stewart, W. J. Taggart, S. H. S. Taylor, B.A., R. B. Thomson, Nettie B. Turnbull, A. P. Wall, D. R. P. Walther, J. D. Wells, H. M. Whittell, Richard Wilkins, H. C. Wilson, Marian E. Wilson, and James Young.

Second Professional Examination.—R. T. G. Aickin, John Allen, G. W. Armstrong, Agnes Balfour, William Basson, John Brennan, Robert Buchanan, Samuel Burns, Harry Caird, T. P. Caverhill, D. Halliday Croom, F. D. Crosthwaite, Alice M. Ebden, H. N. Fletcher, F. H. Gibson, T. M. Guthrie, George Harrison, G. W. Harty, Isabel Hill, Janette T. Hill, T. J. H. Hofmeyr, F. E. Larkins, F. T. C. Linton, M.A.; C. D. Lochrane, J. M. Lovett, Alexander Lundie, Henry MacCormac, J. W. M'Ewan, N. D. M'Kay, William Mackenzie, H. C. Martin, A. G. M. Middleton, C. R. P. Mitchell, G. I Moriarty, Helen Morison, Thomas Nicol, C. F. A. Oberlander, Labbhu Ram, Charles Reece, W. J. D. Robertson, W. S. Robertson, L. C. Robinson, J. A. Ross, F. G. Saleeby, William Sanderson, D. J. Scott, J. E. Scott, M.A.; W. H. Selby, W. H. Simpson, J. Henderson Smith, Effie Stuart, John Tait (with distinction), E. J. Taylor, T. T. Thomson, J. P. du Toit, E. A. Turpin, Caroline Twigge, R. M. Walker, J. H. D. Webster, Leonard West, R. M. Manwaring White, W. C. P. White, W. Y. Woodburn, A. C. T. Woodward. *Old Regulations.*—F. R. Bremner, L. A. Drake, S. C. Roy.

Third Professional Examination.—Ninn H. Beath, Constance A. Bennet, G. S. Blandy, J. G. Briggs [illegible] W. C. Burton, E. E. Cassaday, [illegible] H. L. Cumming, Henry Curwen, [illegible] Fairbairn (with distinction), Ag[illegible] R. G. Gordon, J. A. Gray, L. A. Holcroft, C. H. Houghton, John Hunter, Arthur Hutley, Bertha Jex-Blake, J. M. Johnstone, W. F. Knight, W. S. Laidlaw, Abraham Leach, A. B. Leakey, J. C. London, A. W. B. Loudon, J. G. M'Caughey, Alexander M'Ewen. Daniel Mackinnon, Evan Macmillan, J. B. Mason, E. L. Meynell, R. C. Monnington, E. J. Morton, Robert Murray, Charles Nelson, J. H. C. Orr, Harry Overy, A. C. Owen, D. E. S. Park, John Politachi, E. C. Pritchard, A. F. H. Rabagliati, J. A. Raubenheimer. David Sandler, G. D. Sloan, M. W. Smart, Baba M. S. Sodhi, David Sutherland, A. B. M. Thomson, J. F. van de S. de Villiers. *Passed in Pathology.*—G. M. Brunton.

FOREIGN UNIVERSITY INTELLIGENCE.—*Göttingen:* Dr. W. Weber has been recognised as *privat-docent* of

Mental Diseases —*Heidelberg* Dr Julius Hegener has been recognised as *privat docent* of Otology and Dr Martin Jacoby as *privat docent* of Pharmacology Dr H Braus of Wurzburg has been appointed Extraordinary Professor of Anatomy —*Jena* The chair of Pharmacy, vacant by the retirement of Dr Seidel, has been offered to Dr Kionka of Breslau Dr Berger has been recognised as *privat docent* in the Medical Faculty Dr Maurer of Heidelberg has been appointed to the Chair of Anatomy in place of Dr

Baudry has been allowed to nal Pathology for that of the appointment of Dr de Dr Weill has been appointed to the Professorship of Children s Diseases —*Philadelphia* (*Polyclinic*) Dr Francis R Packard has been appointed to the chair of Otology in succession to Dr Seiss resigned —*St Petersburg* (*Military Medical School*) Dr Richard Peters has been recognised as *privat docent* of Children s Diseases — *Wurzburg* Dr Jacob Riedinger has been recognised as *privat docent* of Surgery and Dr Paul Römer as *privat docent* of Ophthalmology

CORNWALL COUNTY LUNATIC ASYLUM, BODMIN —At the meeting of the Cornwall County Council held on August 6th it was decided to apply to the Local Government Board for sanction to a loan of £105 000 for the purposes of the extension of the county lunatic asylum The present building accommodates nearly 800 patients, and the overcrowding of the institution has engaged the attention of the authorities for some time The plans of the proposed extension which have been approved by the Commissioners in Lunacy and the Secretary of State, will provide accommodation for 400 patients When the new buildings are completed it has been decided that nearly the whole of the present asylum shall be allotted to female patients The total accommodation will be for 510 male and 542 female pauper lunatics In the private asylum 49 patients are admitted, making an aggregate of 1101 patients

WORKHOUSE INFIRMARY NURSING DEPUTATION TO THE PRESIDENT OF THE LOCAL GOVERNMENT BOARD —A small deputation from the Workhouse Infirmary Nursing Association consisting of the Hon Mrs J G Talbot (vice president of the association and chairman of the executive committee), the Viscountess Knutsford (a member of the executive committee) Miss Wilson (treasurer) and Miss Gill (secretary) was received on August 2nd at the House of Commons by the Right Honourable Walter Long M P President of the Local Government Board Mr J G Talbot M P, introduced the deputation Mr S B Provis C B (permanent secretary to the Local Government Board) Mr W F Knollys C B (assistant secretary) and Dr A. H Downes (Poor law medical inspector) were present The object of the deputation was to discuss details of a statement which had been submitted by the association to Mr Long early in the year touching upon the present condition of the nursing in country workhouse infirmaries and the dearth of nurses obtainable for those infirmaries The President of the Local Government Board listened to the members of the association most attentively and clearly showed that he took considerable interest in the questions at issue Ample time was placed at the disposal of the delegates and some important points were discussed The serious dearth of nurses available for the Poor law service was brought forward as the main cause for action and the Local Government Board were urged to adopt measures for the special training of nurses for workhouse infirmaries It was suggested that it might be practicable to train nurses in the metropolitan and other Poor law infirmaries of adequate size and organisation and to bind them to the service as Government officials to work for a definite period in provincial and country workhouse infirmaries as well as in metropolitan The desirability of a sub-department of the Local Government Board being formed to deal with the whole question of nursing in workhouse infirmaries was urged by the deputation Mr Long intimated that he had under consideration the possibility of making alterations in the existing regulations affecting the position of nurses in workhouses and infirmaries He promised careful consideration of the suggestions made by the deputation but was unable to hold out much hope that the Local Government Board could themselves undertake the training and placing of nurses

VACCINATION AT BATH —At the meeting of the Bath Board of Guardians held on August 7th it was reported that from July to December, 1900 824 births were registered in the city of Bath 499 children were successfully vaccinated, six were insusceptible, the parents of 63 had certificates of conscientious objections, 82 had died unvaccinated, in 39 cases vaccination was medically postponed, 38 children had removed to places unknown, and 97 were unaccounted for During the year 1900 90 certificates of conscientious objection were received by the vaccination officer and for the half year ending June 30th, 1901 72 such certificates were received

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN —The Mabel Webb Research Scholarship for the encouragement of original work in pathology physiology, or chemistry will be given in October to a past or present student of the school Candidates must state the nature of the work which they propose to undertake in one of the above branches of study and the holder of the scholarship is required to keep the lecturer or lecturers in the department selected informed of the progress of the work The value of the scholarship is £30 a year for two years Applications will be received up to Sept 1st and should be sent to the secretary, 8 Hunter street, London, W C

AT Woodtown, Devon, on August 2nd, an inquest was held respecting the death of an infant which occurred shortly after birth The nurse who attended the mother stated that the child cried lustily at birth but expired five minutes later A medical man who was called in about three quarters of an hour after birth stated that death was due to strangulation owing to the umbilical cord being round the neck of the deceased and added that if the nurse had been more experienced she could have remedied this The coroner in summing up remarked that the nurse, a single woman aged 23 years was too young to undertake midwifery duties and although there was no criminal neglect in this case he advised the nurse not to act in other cases until she had had more experience The jury returned a verdict of Death from accidental strangulation and endorsed the remarks of the coroner

Parliamentary Intelligence.

HOUSE OF COMMONS

THURSDAY AUGUST 8TH

Ptomaine Poisoning

MR CHANNING asked the President of the Local Government Board whether he would direct an inquiry into the circumstances attending the ptomaine poisoning of two ladies by decomposed cream and whether he would take prompt steps to check the improper use of preservatives to enable articles of food to be disposed of to customers when in a state of decomposition dangerous to health —Mr WALTER LONG replied I have seen a newspaper paragraph as to the inquest in the case mentioned in this question and I will endeavour to obtain a report from the medical officer of health of the borough on the subject I expect to receive in a few days the report of the Departmental Committee on Food Preservatives and I hope then to be in a better position to judge how dangerous decomposition in food may be satisfactorily prevented

The Study of Mental Pathology

Mr WILLIAM JOHNSTON asked the Chief Secretary to the Lord Lieutenant of Ireland whether having regard to his reply to the deputation which waited on him in Dublin concerning a proposal to establish a pathological laboratory devoted to research in connexion with insanity for the asylums of the country he could introduce a clause into the Local Government (Ireland) Amendment Bill empowering county councils to [illegible] support of such a central laboratory for the study of mental pathology —Mr WYNDHAM replied Such a clause could not be inserted in the Local Government Act Amending Bill but it would be pertinent to the Lunacy Bill now before the House I earnestly hope to be able to introduce an amendment of this character into the latter Bill

The Nursing Question in Ireland

This question was [illegible] in Committee of Supply on the vote for the Local Government Board in Ireland —Mr WYNDHAM insisted that the nursing in Irish workhouses had not reached a sufficiently high level and that the Local Government [illegible] to raise it and the announcement that [illegible] nursing order though [illegible] to arrange [illegible] still had done good work [illegible] of nurses they were [illegible] in [illegible] the rules of their orders to assist in certain cases of operations and it was obvious that in addition to [illegible] them [illegible] fully-qualified nurses As to the recognition of training in the smaller hospitals and infirmaries that was a matter within the jurisdiction of the Board and he undertook that the Board would give it immediate consideration

Friday, August 9th.

The Army Medical Service.

Major Rasch asked the Under Secretary of State for War whether he could state when the report of the committee on the Army Medical Department would be ready, and if it would be published.—Lord Stanley replied: I am not able to say when the report of the departmental committee will be ready. The question of its publication does not therefore arise at present.

Medical Research in Ireland.

Mr. Field asked the Chief Secretary to the Lord Lieutenant of Ireland (1) whether he was aware that the English Local Government Board had at its disposal a yearly grant of funds for the purpose of promoting scientific investigation; and (2) seeing that the Irish Local Government Board had not at its disposal any sum for a similar purpose, would he recommend the placing of the Irish Local Government Board in this respect on the same footing as the similar Board in England.—Mr. Wyndham replied: The vote for the English Local Government Board contains provision of a sum of money for "auxiliary scientific investigations" in connexion with the medical department of the Board. I am inquiring as to the special objects with which this money is voted; until I receive information on this point I cannot reply to the suggestion in the second paragraph.

Monday, August 12th.

Vaccination Exemptions.

Mr. Corrie Grant asked the Home Secretary whether he was aware that William Venables of Thornton Hough was granted an exemption from vaccination as a conscientious objector by the Birkenhead county magistrates for his first child in June, 1899, and that he was refused exemption by the same court *in July, 1901, for another child*, then under four months old, and whether there was any way in which he could obtain exemption for this child also.—Mr. Ritchie replied: The facts are as stated. It appears that in the second case the applicant failed to satisfy the justices of his conscientious belief that vaccination would be prejudicial to the health of the child in question. It is open to him to apply to any other justices for a certificate of exemption until the child attains the age of four months.

Civil Surgeons in the Army.

Dr. Thompson asked the Financial Secretary to the War Office if civil surgeons now serving with His Majesty's Army in Great Britain and Ireland were entitled to an increase of salary after three years' service, and also to a gratuity of £100 on completion of their engagement.—Lord Stanley replied: No, they are not so entitled, but the question of the increase of salary is receiving consideration.

The Compound Titles of Retired Army Medical Officers.

Dr. Thompson asked the Financial Secretary to the War Office if he would consider the advisability of abolishing the compound titles of retired army medical officers.—Lord Stanley replied: This question has been very carefully considered and it was not held advisable to abolish the compound titles except in the case of retired officers who were recalled or re-employed.

Tuesday, August 13th.

The Ambulance Experiments.

Mr. Round asked the Financial Secretary to the War Office whether he could state what progress had been made in the construction of ambulances of a lighter character than those used at the commencement of the war in South Africa; and if those sent out during last year, as stated by Lord Raglan, had give [illegible] —Lord Stanley replied: Experiments are still [illegible] proved ambulance and a special committee is [illegible] t. No reports have been received in regard to the wagons referred to in the last paragraph.

The New Factory and Workshop Legislation.

The Report stage of the Bill to amend and consolidate the Factory and Workshop Acts was taken at this and the previous sitting of the House. The subjects discussed had not, as a rule, any special medical interest and therefore need not be dealt with in any detail. After a very long debate the House decided by a majority of 22 votes to confirm the action of the Grand Committee in making mid-day the time for "the Saturday stop" in textile factories. The laundry question was also debated at great length, the decision of the House with regard to it being to omit the laundry clause altogether and to leave the law as it stands.—On the motion of Mr. Ritchie words were inserted in the Bill providing that no meal shall be taken in any factory or workshop where lead, arsenic, or other poisonous substance is so used as to give rise to dust or fumes.

Wednesday, August 14th.

The Study of Insanity.

On the motion of Mr. George Wyndham the following clause was inserted in the Lunacy (Ireland) Bill—viz: "The committees for any two or more distinct lunatic asylums may agree to unite in providing and maintaining a laboratory for pathological research in connexion with insanity and nervous diseases, and may defray the expenses incurred in pursuance of an agreement under this section by contributions from the funds at their disposal for the maintenance of their respective asylums."

Godson.—On August 9th, at Linden House, Cheadle, Cheshire, the wife of John H. Godson, M.B., B.S. Camb., of a daughter.

Hawkins.—On August 5th, at London-street, Reading, the wife of Francis Henry Hawkins, M.D. Edin., M.R.C.P. Lond., of a daughter.

Newbolt.—On the 13th August, at 42, Catherine-street, Liverpool, the wife of George Palmerston Newbolt, M.B., F.R.C.S., of a son.

Probyn Williams.—On August 5th, at Welbeck-street, the wife of R. J. Probyn Williams, M.D. Durh., of a daughter.

DEATHS.

Aldridge.—On August 7th, 1901, at Belle Vue House, Plympton, Mary [illegible] Plympton House, [illegible] Norwood, Samuel [illegible] 81st year, Charles [illegible]

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A PRESCRIBING QUACK.

An inquest held by Mr. Wynne Baxter at Stepney at the beginning of the week served to introduce to the public, not for the first time, the dangerous habits of one J. C. Purdue, F.C.S.M., a herbalist. The deceased was a male child, aged 12 months, who had been taken by the mother to Purdue's establishment—a druggist's shop having the words "Botanical Herbalist" over the door. According to the mother [illegible] "doctor," Purdue [illegible] liniment for which [illegible] worse he was to be [illegible] due seems to have sounded him, prescribed lemon juice and barley water, visited the patient, and finally advised sending for "another doctor," whom he recommended. Purdue in his evidence, which will be found fully reported in the *Daily Mail* of August 14th, described himself as a "registered herbalist ... registered in 'Kelly's Directory,'" and said that his previous conviction for pretending to be a medical man was "a most disgraceful thing brought about by 'two malicious doctors.'" A juror asked if Purdue was known as the "tea leaves doctor," and Purdue handed to the coroner a paper, which appears to have been an Act of Parliament of Henry VIII. relating to witchcraft and sorcery, under which he claimed to carry on his business of prescribing unmolested. The coroner was not much impressed by Purdue's attempt to obtain a legal status, for he told him that he was "acting as a pirate and imposing on these poor people." Mr. Charles Welch gave evidence that it was not possible to say for certain that calling in a medical man would have saved the infant's life, and described Purdue's nostrum as "smelling very much of Worcester sauce." The coroner said that the bottle was labelled "J. C. Purdue, F.C.S.M., London. Safe Medicine. Member of the Magnetic and Botanic School of Safe Medicine, London. Founded 1893. Advice gratis daily." *He asked if any society would take up the prosecution* of Purdue. We suppose that the London Society of Apothecaries will have no difficulty in securing Purdue's conviction. He is an old and hardened offender. At the beginning of last year we recorded the death under his hands of a man with pulmonary trouble (THE LANCET, Jan. 27th, 1900, p. 234) and there is no doubt that he has for years been trading upon the ignorance of the sick poor by pretending to be a medical man. The cruelty of such offences as Purdue's lies in the fact that the quack deprives the sick poor, if they are very ill, of their chance of recovery. Many patients might be saved if the medical man could see them early enough. Impostors like Purdue waste the precious time of the sick by telling them lies while they exhibit silly potions of tea or barley water. Then when it is obvious that the case is going to the bad and probably when the patient's funds are running low, a medical man is called in—too late. At the inquest it is impossible to say for certain in any particular instance, whatever may be the probabilities, that the life could have been saved, and so the charlatan *gets off*. We hope that an exemplary fine may soon bring Purdue to [illegible] laws of his country. We do not sup[illegible] him that he is a mischievous ass, [illegible] maker.

WANTED—A SCHOOL.

To the Editors of THE LANCET.

SIRS,—I should be obliged if you would allow me to ask in your columns whether there is any school for the orphan daughters of medical men to which I could apply for the admission of my youngest daughter, aged 12½ years. My husband, who was formerly a student of Charing-cross Hospital, died in 1899, leaving me with two young daughters. At the time of his death he had been in independent practice only a short time and had not been able to make provision for us. He had recently lost nearly all his small capital in an unfortunate speculation. I have been obliged to break up my home and to accept a position as housekeeper and am unable to support my youngest child. The eldest is in the care of friends and is receiving a good education. I should be very grateful if any of your readers would kindly give me the name of a school to which I could apply for the admission of my daughter, who is a healthy girl.

I am, Sirs, yours faithfully,

EVELINE GREENLEAF.

Emile Villa, Sunny-gardens, Hendon, August 12th, 1901.

VACCINATION FEES.

To the Editors of THE LANCET.

SIRS,—I have a non-dispensing practice in the suburbs of a large provincial city and charge 3s. 6d. (my lowest fee) for vaccinating children of £1 1s. confinements. Each case is done with calf lymph which costs me 8½d. I should be glad if your readers would kindly tell me if my charge is above the ordinary for such cases, as I have been told lately several times that I charge more than my neighbours.

I am, Sirs, yours faithfully,

August 14th, 1901. M. S.

GRUESOME SUPERSTITIONS.

To the Editors of The Lancet.

Sirs,—In The Lancet of July 6th, p. 41, you refer to "the bleeding Host." Could any of your readers kindly give me some particulars of this reported miracle or tell me where I might obtain details of the same? I should like to know, for example, when first the miraculous power or powers were claimed, their nature and extent, and the circumstances under which they were manifested. Is there any publication on this subject? I can find none. Some time ago you had a reference to dead bodies submerged being located (or alleged to be located) by means of a loaf of bread. Kindly give me the date of this article. Does any reader of The Lancet know of any book or monograph dealing with the subject of trial by ordeal?

I am, Sirs, yours faithfully,

August 6th, 1901. Corpus Vile.

⁎ The note on the location of a drowned body will be found in The Lancet of Nov. 24th, 1900, p. 1536.—Ed. L.

THE KEELEY INSTITUTE.

To the Editors of The Lancet.

Sirs,—Can you favour me with any information about the "Keeley Institute" for the cure of intemperance? I know there have been occasional paragraphs in The Lancet, but unfortunately I send my copies of The Lancet on to a friend, and do not retain them. I daresay you can guess the facts leading to my query—the village "Lady Bountiful," anxious to do anything *to reclaim a neighbour rapidly drinking* himself to ruin and death, and an appeal to me. Of course, on the face of it, it looks like quackery, and probably is, but with the ethical part of the business I have nothing to do, as I should certainly not take any personal action in the matter. Do you happen to know if there is anything in the treatment? The "double chloride of gold" at eight guineas a week reads like bosh, and the "cures" may possibly be on a par with the "Mother Seigel's Syrup" testimonials. But these good ladies, from the most charitable motives, want to do something and are caught by the glamour of the name of Canon Fleming. And I have promised to get what information I can. If you can help me I shall be grateful.

I am, Sirs, yours faithfully,

August 12th, 1901. Provincial.

⁎ Our correspondent will find some information as to the absurd so-called Keeley Cure in Vol. II. of The Lancet for the year 1892.—Ed. L.

AMERICAN MEDICAL DEGREES IN NEW ZEALAND.

To the Editors of The Lancet.

Sirs,—I should be obliged if you would kindly answer the following questions, through the medium of The Lancet. 1. Can a person term herself "Doctor" (if she does not practise) if she holds no diplomas? 2. Can a person who holds a bogus (or bought) diploma legally use the title of "Doctor" and place a brass plate outside the *door* with "Dr. ——, M.D.," on it? 3. If you know that a person holds a diploma from a college (which is registered in the U.S.A.), but which also sells such diplomas, would one be justified in saying that such person was unqualified (even if they seemed well informed as *regards* medicine, &c.) and held a bogus diploma, or would such be actionable? 4. Can you inform me whether the diploma mill of Dr. Armstrong, People's Institute, Buren-street, Chicago, is *still in* existence, and what punishment was meted out to Dr. Armstrong for making use of the mails to defraud? (see The Lancet, Dec. 1st, 1900, p. 1621). 5. Where could one obtain reliable information as to which are the bodies in the United States of America which are able to grant diplomas which would be recognised in Great Britain? Is there any book issued by their Government which would give one information? 6. Could a person practise in the United States with one of these bogus diplomas? 7. Would the following gentlemen, whose qualifications are appended and who are upon the New Zealand Medical Register, be able to register themselves upon these qualifications in Great Britain? M.D. Bellevue Hosp. Med. Coll., New York, U.S.A.; M.D. Jefferson Med. Coll., Philadelphia, U.S.A.; M.D. Univ. Lake Forest, Chicago, Illinois, U.S.A.; M.D. Univ. Michigan, U.S.A.; M.D. Homœopathic Med. Coll. of Missouri, U.S.A.; M.D. Michigan Coll., U.S.A.; M.D. Cooper Med. Coll., San Francisco, U.S.A.; M.D. Univ. Iowa, U.S.A.; M.D. Univ. Southern California, U.S.A.; M.D. Detroit Coll. Medicine, U.S.A.; M.D. Cincinnati Coll. Med. and Surg., U.S.A.

Would you kindly reply to me through the columns of The Lancet, and oblige Yours faithfully,

May 29th, 1901. Porirua.

⁎ 1. It would seem (we refer to this country) to be open to anybody to call himself or herself "Doctor." But if an unqualified person attempts to obtain money or to pass in the public eye as a qualified practitioner he can be prosecuted by law. 2. The owner of a bogus diploma is not qualified, and our correspondent is referred to the answer to the first *question*. 3. We cannot say without knowing what the institution referred to is. 4.—We understand that the People's Institute, Chicago, has been abolished. We do not know what punishment his country meted out to Armstrong. 5. The University of the *State of* New York (Albany) issued last year from the College Department certain hand-books on professional education in the United States; the volume *dealing* with medicine, price 45 cents, contains the information required. 6. This question cannot be answered, as *different* States, unfortunately for the United States as a whole, have different arrangements in these matters. 7. The list of institutions the medical degrees of which can be registered in Great Britain, if obtained prior to June 25th, 1886, but only *in addition* to, not in place of, British qualifications, will be found in the current Medical Register, page 78. The two first institutions named by our correspondent are also on the list in the Medical Register.—Ed. L.

THE METHODS OF A PUBLIC VACCINATOR.

We have received the following specimen of a circular which has been sent by a public vaccinator to a lady in a certain district. Why we have only now received it when it is nearly three months old we do not know, but although it is old it is none the less worthy of *comment*.

"——, May 16th, 1901.

Dear Madam,—As Vaccination Medical Officer of this District, I must ask you to give your earnest and best attention to your little one's case.

The new Act is rich in blessings, proved by the following important facts, which I will explain in a few simple words.

1st. The calf lymph from Government is so carefully selected and tested that its *purity is absolutely guaranteed.*

2nd. The comforts and convenience of the mother are *assured* by the medical officer attending the home and arranging the *almost painless operation in less than two minutes*, with strict regard to gentleness and sanitation.

3rd. Visits, posting certificates to the authorities, and *securing* the mother from future trouble *free of all cost.*

I am very anxious with regard to this grave duty which all of us owe to our families and the public—namely, *protection* from one of the most contagious, deadly, and repulsive diseases, the horrible plague of small-pox.

I am, dear Madam, sincerely yours,

——, M.D., M.R.C.S., L.S.A."

We have no hesitation in saying that this is an improper document for a public vaccinator to circulate. It is part of a public vaccinator's privilege to try to secure that his district should be properly vaccinated, but it is not part of his duty to try for a monopoly of the operations. Such a circular as the one we have quoted could only lead to ill-feeling between the public vaccinator and his professional brethren in the district.

PRESERVING AND MOUNTING MOSQUITOES.

M. I. Cross has the following note in the August number of *Knowledge* with regard to the mounting of mosquitoes.

> "Some time has elapsed since the connexion between mosquitoes and malarial fever was established, yet satisfactory specimens of the former have reached England in very small numbers although medical men and others who are interested in the matter have constantly wished to obtain them. The reasons are that the unmounted specimens are not put up in suitable preservative medium for travelling, or if they are mounted sufficient care has not been exercised in the process. Several methods have been published in medical papers on the subject of preserving mosquitoes, but none of them are really satisfactory ones. The following will be found to answer the purpose. To send unmounted mosquitoes by post they should be preserved in dilute alcohol, two parts of rectified spirit to one part of water. Too many should not be put in one bottle or they become entangled and broken. To make permanent mounts dilute glycerine, say one part glycerine to two parts water, in a shallow cell will be found best. The following is the process:—1. Remove the dilute alcohol and soak in water until all trace of the spirit is removed. 2. Soak in dilute glycerine for about 12 hours. 3. Make cell and when dry fill up with dilute glycerine and carefully place the specimens in it and apply the cover-glass. Should the mosquito be too opaque after soaking in water place it in a strong solution of carbolic acid for a few hours and when transparent wash in water, then place in dilute glycerine."

"PUBLICITY."

To the Editors of The Lancet.

Sirs,—In reference to the above in The Lancet of August 10th, p. 430, may I point out that the practice of inserting in the Irish papers that Dr. So-and-So has left his address for London or elsewhere or has returned to his residence from such-and-such a place, is very common amongst practitioners in Ireland. Hardly a day passes but you will see in the "fashionable" columns of the *Irish Times*, *Freeman's Journal*, &c., such a paragraph. In consequence, as much out of curiosity as otherwise, I about two to three years ago wrote to the secretary of the General Medical Council asking if an intimation in the daily papers such as I have referred to constituted medical advertising or not. In reply I was told that the General Medical Council could not express any opinion on the matter. Determined, then, if possible, to get a definite statement on the point I watched my opportunity and shortly afterwards noticed the following announcement—the text may not be exactly right, but it is not far out—in the *Irish Times*—viz.: "Sir William Thomson, M.D., President of the Royal College of Surgeons in Ireland has returned to 54, St. Stephen's Green, Dublin, from attending the meeting of the General Medical Council." Sir W. Thomson is, I believe, the representative of the Royal College of Surgeons in Ireland on the General Medical Council. Immediately on its appearance I wrote to Sir William Thomson and asked him if he had it inserted, and, in any case, if he did not think the publication of his name and address in such a manner amounted to advertising in a professional way.

After a lapse of a few weeks I had an answer from the secretary of the council of the Royal College of Surgeons in Ireland saying that he was instructed to say in reply to my letter to Sir William Thomson that the Council of the Royal College of Surgeons in Ireland sanctioned the insertion of such paragraphs I believe the paragraphs referred to in the Irish papers are published by the parties themselves or at least with their knowledge and consent. After such an admission I cannot see that Dr Fenton has sinned in any way, even if he inserted the paragraph you take exception to and which was published in the *Daily Telegraph* of August 2nd last

I am Sirs yours faithfully,
WHAT IS SAUCE FOR THE GOOSE OUGHT TO BE SAUCE FOR THE GANDER

THE WARREN FOUNTAIN PEN

MESSRS BINGE WARREN, AND RIDGLEY of Great Saffron hill, London E C, have sent us one of their Warren fountain pens The price is 5s the nib is described as of 14-carat gold, and the mechanism is extremely simple

"GRAND OPENING FOR A MEDICAL MAN"

To the Editors of THE LANCET

SIRS,—I have been "taken in by the alluring advertisements of house agents anxious to sell and to let their houses In four instances recently the reply I got from each agent was that a grand opening for a medical man existed In three I find the information given to be false, in each case the house had just been vacated by the occupier (a medical man) who had gone across or a few yards down the road The chances of success in each case were very small I write this after having been put to unnecessary and cruel expense

I am Sirs yours faithfully,
August 14th, 1901 C W HARRINGTON L R C P

Medicus writes :—"Can any reader of THE LANCET tell me the publisher of a work by Professor Schutter of Berlin University on the cancer bacillus?

*** In this connexion our correspondent's attention may be directed to the letter from our Berlin Correspondent in our present issue, p 494 —ED L

◆

Mr B Brocks —THE LANCET is not a fashion paper and we do not give advice upon complexion Yet our correspondent might consult [illegible] He will there find various recipes [illegible] practised by Sir Joshua Reynolds [illegible] him a wrinkle (we would even say many wrinkles) if he tries them

M.R C S M P S—With much of the letter we are in accord but it is not worded in a way likely to ensure it attention If the scheme is to receive serious notice it must not be anonymous

A B G—The procedure which our correspondent advocates has been referred to already in our columns

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS" and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "*To the Sub-Editor*"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed* "*To the Manager*"

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index to Vol I of 1901, which was completed with the issue of June 29th and the Title page to the Volume, were given in THE LANCET of July 6th

VOLUMES AND CASES

VOLUMES for the first half of the year 1901 are now ready Bound in cloth, gilt lettered price 18s, carriage extra.

Cases for binding the half year's numbers are now ready Cloth, gilt lettered, price 2s, by post 2s 3d

To be obtained on application to the Manager, accompanied by remittance

An Address
ON
THE TREATMENT OF TUBERCULOSIS IN SANATORIA.

Delivered before the State and Municipal Section of the British Congress on Tuberculosis on July 26th, 1901,

BY SIR JAMES CRICHTON-BROWNE, M D. EDIN, LL D ST AND, F.R S LOND & EDIN

MR. CHAIRMAN, LADIES, AND GENTLEMEN,—I have undertaken to direct your attention, in the few words I am permitted to address to you, to one narrow scroll of that vast and voluminous subject which is now being discussed in four sections and in many phases by the distinguished men assembled in this metropolis

It is to the subject of sanatoria, or special hospitals for the cure of tuberculosis and more particularly of pulmonary consumption that I have to bring under your notice, and in *saying that I use the word "cure" advisedly* I am aware that pessimistic views as to the curability of consumption are still entertained in some quarters The dictum of Laennec echoing the current opinion of his time, "que l affection [illegible]
absolumen [illegible]
rity, has c [illegible]
ing, shado [illegible]
recently D [illegible]
matters are entitled to respect, has repudiated the word "cure' and strongly urged that we should not commit ourselves to anything beyond an arrest of pulmonary tuberculosis Now, I venture to differ from Dr Theodore Williams on this point, and the difference between us is no mere logomachy but an essential one, calculated to affect the usefulness of sanatoria, for if all that these institutions can offer is an arrest—that is to say, an interruption or stoppage, more or less prolonged, in the course of an incurable disease—they will not commend themselves to public confidence and support as they would do if they could hold out hopes of a complete and permanent restoration to health

No doubt every severe disease by which the human body is visited leaves some residual traces behind it—some scars on the constitution, but for practical purposes these do not count unless they are kept in perpetual remembrance by the suffering they inflict or the disability they involve It is the rarest occurrence to find at a necropsy any human body in which no pathological changes are visible beyond those incidental to the disease that killed or to senile decay In almost every cadaver there are what might be called the fossil remains of palæozoic disease, but because we observe in the ileum the obliteration of some of Peyer's patches we do not say that an attack of enteric fever which happened perhaps 40 years ago was arrested and not cured, because we find on the breast a cicatrix marking the site of a carcinomatous tumour removed 10 years previously we do not maintain the incurability of cancer Then why, I would ask, should the presence of a calcareous nodule or fibrotic patch at the apex of a lung justify us in arguing that phthisis, once planted is ineradicable? The assumption that the tubercle bacilli are lurking in such foci merely waiting the opportunity given by some deterioration of health or lowering disease to break forth again and to spread havoc around is gratuitous, for when in such cases phthisis does again supervene it is just as likely to be due to fresh infection as to any stirring up of slumbering embers Even when caseous masses in which tubercle bacilli can be detected exist in the lung so long as these remain com- [illegible]

tubercle exists in the lungs of a large number of persons who are unconscious of its existence, who carry it about with them for years, and who ultimately die from other diseases. Dr J Kingston Fowler found that in 2400 post-mortem examinations at the Middlesex Hospital quiescent and extinct tuberculous lesions existed in 9 per cent, while Loomis has recorded a similar state of matters in 71 out of 763 necropsies in New York. Vibert, in Paris, has reported that out of 131 persons *who met with violent deaths and* were examined at the Morgue 17 had healed tuberculous lesions in their lungs Within the last month Dr Frederick P Hearder has carefully analysed for me the last 500 consecutive post mortem examinations of persons from 15 years of age upwards dying in my old hospital, the West Riding Asylum, Wakefield with the result that in 170 of these—that is to say, in 39 2 per cent —tuberculous lesions existed In 93 cases (or 18·6 per cent.) there was active tubercle, and in 103 cases (or 20·6 per cent) there was obsolete tubercle, appearing as contraction and cicatrisation in 24 cases (or 4 8 per cent.), as fibrosis in 35 cases (or 7·0 per cent), as calcification in 23 cases (or 4 6 per cent.), and as encapsulation in 21 cases (or 4·2 per cent) These figures are significant as showing the tremendous prevalence of tuberculosis amongst the insane in asylums and as showing also how tubercle once rendered obsolete may continue so even under conditions most favourable to its renewed activity In 103 persons in whom pulmonary tuberculosis had become obsolete before their admission to the asylum or during their residence there it remained in that state in spite of the impaired nutrition and depressing conditions almost invariably associated with mental disease, and in spite of association in the wards of a large institution with other patients in whom that malady was in its active stages The cure in these cases, such as it was, held good to the last even when it might have been expected to have broken down

No doubt in a large number of cases of consumption, especially in its more advanced stages, a condition that can only be correctly described as an "arrest" is arrived at Pyrexia and the more acute symptoms subside, bacilli are no longer found in the sputum, and there is improvement in general health and diminution of the local physical signs but wheezing, breathlessness, occasional cough loss of strength, and chronic invalidism remain with a constant liability to relapse. In such cases the disease is smouldering but not extinct. But in other cases—a still larger and, we trust, an ever increasing number—what is practically a favourable termination of the disease is reached. The local lesions cease to give trouble the constitutional symptoms vanish, energy and bread earning capacity are restored, a ripe old age is attained with scarcely a reminiscence of the phthisical past, or a long interval of good health is enjoyed before the disease again declares itself. In the two cases which Dr Theodore Williams in his recent paper adduces to illustrate the inveteracy and incurability of phthisis complete immunity from symptoms was enjoyed in one for 19 years and in the other for 11 years Surely under such circumstances it is a misnomer to describe the long interval of health as an arrest—or as anything but a cure of the disease. Koch has cited cases in which tuberculous foci of large size have subsequently contracted and cicatrised and permanently healed and in his judgment the curability of pulmonary tuberculosis in its earlier stages is an indisputable fact. Even a whole lung may be destroyed and shrivelled and the other lung preserved in its integrity But it is in cases less pronounced, where slight infiltration at the apex in young persons from 15 years to 30 years of age undergoes resolution or caseation or fibrosis, that what may be called genuine cures are obtained. In them often enough all unpleasant symptoms disappear, and they remain unmolested by the bacilli for the rest of their days

The pathological evidence of the curability of consumption is convincing and so is the clinical We see cases in what used to be called the pre tuberculous stage but which we now know by the presence of bacilli to be incipient tuberculosis, in which complete resolution with disappearance of local [illegible]
the advantage now to one and now to the other In the long drawn-out struggle, so stubborn is the resistance of the tissues to the invader that our *belief is almost revived in the* exploded *vis medicatrix naturæ* and we see that, even unaided the assailed lung is largely capable of protecting itself The observation of a large group of cases brings home to us the truth that consumption is susceptible of spontaneous cure and

powerfully suggests that in many instances its progress might be stayed and its ravages repaired by some slight reinforcement of the bodily powers. It is to supply this reinforcement that sanatoria have been established. Consumption, as we now know, does undergo spontaneous cure and there can be no doubt that it has from time to time been cured under, and perhaps sometimes notwithstanding, one and all of the infinitely varied kinds of treatment to which it has been submitted. It is impossible to question the diagnosis or judgment of such a clinical expert and faithful historian as Stokes or Niemeyer when he tells us that he has repeatedly seen complete recovery from consumption take place in patients confined to bed, cooped up in hot rooms, kept on low diet and treated by blisters, setons, and cough mixtures. I am not going to trace the several steps in the evolution of a more rational method of treatment that has landed us to-day in measures exactly the opposite of these I have enumerated. That would be an interesting, but a tedious, task for which I have not time, and I will only say that our present system of treatment, that which is organised in the sanatorium, rests on a scientific basis that is irrefragable and is already abundantly justified by its fruits.

I do not claim finality for that treatment. The time may come—pray Heaven it may!—when some sovereign and speedy remedy for tuberculosis will be put in our hands. The resources of pharmacology are not exhausted. Bacteriological science is advancing at automobile pace and any day an agent may be discovered—an improved tuberculin, an antitoxin, a serum, or a germicide—that will seek out and kill the bacilli in their lairs or render them innocuous. Even now the intravenous injection of formalin, as conducted by Dr. Robert Maguire, seems to have a powerful influence in establishing pulmonary asepsis. But pending the authoritative promulgation of some effectual antidote that will operate directly on the bacilli and their products our best hopes are centred in measures calculated to increase the corporeal resistance to their inroads. These measures, which may be summed up under fresh air, feeding, rest, and medical regulation—these measures alone, we now believe, skilfully employed, are capable of effecting a cure in a large proportion of cases of consumption when taken in time, and even should some prompt and infallible remedy for tuberculosis be discovered they will still continue to be of value in promoting its action and in removing the debility engendered by the malady it has extirpated. It cannot be too loudly proclaimed, too widely known, that sanatorium treatment has already largely extended the curability of consumption and that in suitable cases it holds out hopes of recovery and of prolongation of life that could not have been entertained before its introduction. It is as yet too soon to form any exact numerical estimate of its results. Only approximative computations can be made, and these are subject to correction by the subsequent history of cases and to discount for the too sanguine construction of some of those making them. In Germany, where the open-air treatment has most copiously effloresced—though I am glad to remember that it budded first in England—statistics are more reliable than those available in this country, because they extend over a longer period. The experience of 11 years at Görbersdorf, in 1890 patients, gave in the first stage of the disease 27·8 per cent. cured, 31 per cent. nearly cured, and 58·8 per cent. not improved, and Mr. Rube has told us that of 8200 insured men and women treated in the State Sanatoria in Germany 71 per cent. were discharged fit for work, a criterion, not of cure in all cases, but of substantial improvement. Dr. W. Rowland Thurnam tells me that of 78 patients treated at Nordrach-upon-Mendip in the year 1899 24 per cent. left the sanatorium absolutely cured, being able to return to their ordinary walks of life and with no signs of phthisis remaining, stethoscopic, thermometric, or microscopic; while 24 per cent. left relatively cured, not completely recovered, but still equal to a return to work and to a fairly active life. Amelioration short of relative cure was secured in 37 per cent., and in 18 per cent. there was no improvement or death. The absolutely cured cases have all remained perfectly well up to the present date, the relatively cured have suffered no relapses, and some report themselves as better and quite well, while among the ameliorated cases there have been deaths, relapses, and steady improvement. At the sanatorium at Mundesley there were 66 patients up to the end of last year, of whom 21 were discharged recovered and 31 partially recovered, leaving 14 under treatment or unimproved. A return which Dr. F. W. Burton-Fanning has prepared for this Congress dealing with 716 patients treated in 13 sanatoria gives 37·4 per cent. of recovery or arrest and 40·1 per cent. of amelioration, and Professor Koch has told us that if patients be carefully selected and treatment be sufficiently prolonged it will be possible in sanatoria to cure 50 per cent. of cases or perhaps more. Without attaching undue weight to sanatorial statistics published up to the present date this, at any rate, is clear—that these establishments already give results superior to those of the most successful health resorts like Davos, and it may be confidently predicted that as time goes on, and as their merits become known, so that an increased number of patients in the initial and most curable stage of the disease resort to them for treatment, and as the general adoption of those preventive measures which it is the main object of this Congress to recommend leads to a general reduction in the virulence of the disease, their returns will become more and more satisfactory. In their early days they have had to grapple with a large proportion of advanced and hopeless cases, but as a just knowledge of the nature of the disease and its amenability to treatment is disseminated there will be less contributory negligence on the part of sufferers and their friends and more eagerness in seeking relief.

Seeing that the sanatorium treatment is accepted by the medical profession as, upon the whole, the best treatment of consumption available at present—and the unanimity of the profession on this point is remarkable—seeing that it saves many lives, that it prolongs the days and alleviates the sufferings of those whom it cannot altogether rescue; and seeing that it has the collateral advantage of aiding in the work of prevention by isolating a number of active fountains of infection that but for it would be scattering the seeds of the disease throughout the community,—it behoves us to bring that treatment within the reach of all persons affected by consumption who are willing to avail themselves of it. The sick and the sound alike will benefit by its adoption, the public burdens will ultimately be lightened by its beneficial operation, and it is therefore a public duty to provide it for those who cannot provide it for themselves. This public duty is now recognised in almost all civilised countries. In France, Italy, Russia, Norway, Sweden, Denmark, Switzerland, Austria, Hungary, Poland, Spain, Portugal, and in 11 of the States of the American Republic sanatorial hospitals have been provided, and in most of these countries the Government have seen fit to assist in their erection and maintenance and in some cases to assume the entire responsibility for these. In Germany, which leads the van in this good work, upwards of 100 sanatoria with above 5000 beds have already been called into existence for the treatment of consumptives of the working class, and as the funds for these have been largely contributed by the State Insurance Companies we may accept the fact that additional sanatoria are to be forthwith provided as conclusive evidence that from a financial point of view these hospitals have not been disappointing. It is actuarially established that the cure of consumption on the large scale in the working class, costly though it may be, is, in the long run, cheaper than the expenditure on sick pay and death duties and support of dependants when it is left to run its unrestrained course. The exact mode in which sanatorial accommodation is to be provided must, of course, vary in every different country in accordance with its administrative system, its economical conditions, and the habits of its people; and we hope to hear from foreign representatives some interesting particulars as to the methods adopted in their respective localities, but my duty is simply to introduce the question of sanatorial treatment in England and to prepare the way for Mr. E. W. Brabrook, Sir John Burdon Sanderson, and others who, with abundant knowledge and practical experience, will deal with the topic in several aspects and in greater detail.

Now England has been accused of having lagged behind in this matter, and the remarks which have been made almost suggest that she has been callously indifferent to the sufferings and deprivations of her consumptive poor. But that accusation is not more just than those levelled against her for her inhumanity in war. It is not mere British arrogance, but sober truth, to declare that there is no country in the world where more ample and generous provision has been made for the sick and afflicted of all classes than in England. Consumptives have not been neglected. Our workhouse infirmaries, our sick asylums—some of them quite equal to the best continental hospitals—have always been open to them; our general hospitals, as Dr. P. H. Pye-Smith has pointed out, have not refused them admission; and admirably appointed special hospitals, like those at Brompton, at Victoria Park, and at Ventnor, have been provided by the charitable for their accommodation. With characteristic caution England has not rushed into the new sanatorial movement until thoroughly satisfied as to its feasibility, but now that she is convinced on that point there will be no slackness or delay in her participation in it. The progress made in the work of the prevention or cure of consumption since our National Association for that purpose was formed, and since the King gave it his countenance less than two years ago, has been phenomenal, and at the present moment there is scarcely a county of England in which, either by private enterprise or public effort, a sanatorium is not being built or is not in conten [illegible] work before us at this juncture [illegible] local activity, to determine the [illegible] as a whole and of its several districts, to prevent overlapping and extravagant outlay, and to supply the best advice as to construction and management. And in this work the deliberations of a congress such as ours may afford material assistance. My contribution to these deliberations must be a small one, but I would briefly indicate what it seems to me is wanted in connexion with sanatorial treatment in this country.

In making provision for that treatment we have three classes of consumptive persons to bear in mind: (1) the affluent, (2) the competent, and (3) the indigent.

As regards the first of these, the affluent, they may, I think, be safely left under the guidance of the skilled medical advice which they can command to provide what is necessary for themselves. Consumption is always prevalent in the inverse ratio of rateable value, and the problem of dealing with it amongst the rich is therefore a comparatively simple one. For them I am not prepared to maintain that treatment in a special sanatorium is always essential. I am not blind to the advantages of the discipline maintained in a large establishment conducted with a sole eye to salubrity, or of complete subjection to the will of a medical autocrat with a firm faith in his system and the power of inspiring confidence. But such medical autocrats, indomitable and yet genial, are not everywhere to be found, and sanatoria have their drawbacks as well as their advantages. On a highly bred and highly strung person involvement in an agglomeration of disease may have a depressing effect. For a majority even of the affluent class of consumptives the sanatorium with its simple ways and benevolent tyranny is, I believe, the best place, but I cannot contend that for some of them a private house may not, by architectural device, medical direction, and skilled nursing, be converted into a perfect sanatorium. Nay, I would go further and say that for the affluent the sanatorium is not the kind of treatment to be invariably recommended. It cannot, I think, always supersede residence at high altitudes, in Egypt, on the veldt, or even sea voyages, and those who have every method of [illegible] be guided by the phy [illegible] traits and requirements [illegible] that the sanatorial provision for the affluent in this country is already nearly sufficient. I have seen a list of 22 of these establishments already in operation in England and Scotland, and more are promised, and the law of supply and demand may be trusted ultimately to determine their number and characteristics. But the law of supply and demand—being one of the mills of God—"grinds slowly," if it "grinds exceeding small," and in the meantime, until selection has determined the survival of the fittest, a jealous medical eye should be kept on these establishments. The name "sanatorium" is unprotected, open air is a *fera naturæ* that he who will may capture, and the danger is that incompetent persons without scientific knowledge or practical skill, or unscrupulous persons with a dingy dwelling, a meagre curtilage, and a rickety summer-house designated anew "Nordrach-cum-Wolverhampton"—the Black Country being a substitute for the Black Forest—or "Falkenstein in Finsbury," may draw into their nets unwary patients and discredit the system. It is incumbent on members of the medical profession in choosing a sanatorium for their affluent patients to be well assured of the character and qualifications of its medical head. Some existing sanatoria are admirable; in others there is room for improvement in internal arrangements and domestic management. A rough-and-ready system in the service of food and household economy is no integral part of the treatment, which is not incompatible with daintiness and refinement. To call high-class men who have identified themselves with such establishments "hotel-keepers," as has been done, is a gratuitous insult and a grave injustice. They are hospital physicians giving their whole time to their hospital work and therefore properly remunerated directly and they are conferring valuable services on the public. For my part I think that it is much more desirable that sanatoria for the affluent classes should remain entirely in the hands of medical men than that they should be exploited by limited companies or by lay speculators.

In turning to the "competent" class of consumptives—as I have called those drawn from that large section of our people whose means suffice to furnish the necessaries and conveniences of life without superfluity—we reach the point where eleemosynary aid becomes desirable. As long as health is preserved these persons have ample means of subsistence, and during a brief illness they can meet all requisite charges, but when they are prostrated by a protracted disease that diminishes or cuts off their income and demands a costly treatment their resources are inadequate. Their state is really a pitiable one, for their independence of spirit is not lost in their undeserved poverty and often enough they would rather die than apply for relief. Many of them can contribute some part of the cost of their maintenance and treatment while they are ill, and many of them, if restored to health, would gladly, when again earning money, repay to any institution the expenses of their illness. It is for them—for governesses, curates, clerks, young barristers and medical men and civil servants, and for the wives and daughters of professional men, of farmers, and small tradesmen—that sanatoria should be provided by the subscriptions of the charitable or by the assistance of well-disposed capitalists who are willing to do a good work and receive a very small return for their money. And what charity is ready to do for such sufferers is illustrated by the noble gift of £100,000 to the Mount Vernon Sanatorium at Hampstead, announced this morning. In the sanatoria thus procured a certain number of patients would, if the institutions were to be useful, have to be received gratuitously or on the terms of deferred payment should recovery take place—a payment which should, of course, be always voluntary and never enforced. A majority of the patients, however, would pay for their own board in part or in whole; and my belief, founded on my experience of registered lunatic hospitals, is that, when once built and furnished and fairly started, these sanatoria would, under skilful management, become self-supporting. It is the initial expenses that have to be met. The cost of maintenance when they are launched need not, in sanatoria of 60 beds and upwards, exceed £1 10*s.* or £2 a week—a sum which, considering that the duration of the treatment will be on the average six months, a very large proportion of the competent class should be able to pay out of their own pockets At Pinewood Sanatorium, which has been built out of funds advanced by Mr. Rube and Mr. Lionel Phillips at 2½ per cent. interest, and where we shall have rent at that rate on an outlay of £30,000 to pay, we propose to open with a charge of three guineas a week, which we ultimately hope to reduce considerably. In some of the county sanatoria that are now in view, thanks to local efforts, I have no doubt that treatment on a liberal scale will be put within the reach of those who cannot afford more than £1 5*s* or £1 10*s.* per week, and as several counties which are leading the van in this matter have already, even in these pinching times of war, obtained by public subscription the amount required for their sanatorial needs, I am sanguine that their example and the encouraging reports they will soon be able to issue will stimulate other counties to do likewise, and that voluntary contributions and self-aid will do all that is necessary for the competent class of consumptives in this country. As to the constitution and administration of these sanatoria I shall say nothing now but that they should be constructed in the simplest and most inexpensive style, and that their hospital character should be preserved by the appointment of a staff of consulting and visiting physicians. A resident medical officer must, of course, carry out treatment and superintend every detail of domestic economy, but the patients should have the benefit of the highest medical skill and experience that the district affords. Any medical body or corporation putting obstacles in the way of the acceptance of office in such sanatoria would be incurring a serious responsibility and would have to encounter a heavy reckoning with public opinion.

In the indigent class of consumptives is included the great mass of cases of the disease in this country—all those occurring amongst artisans, workmen, labourers, soldiers, sailors, domestic servants, sempstresses, and shop-girls. The line between them and the class immediately above them socially is not clearly defined; for, of course, an enormous majority of them are competent in the sense that they are supporting themselves and those having claims on them while they are well, and that by virtue of their own frugality they are not wholly or immediately destitute in sickness. They are, however, indigent in the sense that they are all in need of help, of greater or less amount, during any prolonged suspension of work (when also those dependent on them must be maintained)—help which in consequence of their number and distribution must almost inevitably come from public funds. Private charity cannot cope with their necessities and the sanatoria by which that valuable commodity, their skill and labour, is to be preserved to the community when it is menaced by consumption must be paid for out of the public purse. The problem of providing these sanatoria for the indigent is a large one to commence with, but as their curative influence is exercised and as preventive measures come into full operation it will become smaller and easier. It is clear that these sanatoria for indigent consumptives must be distinct establishments and cannot properly be tacked on to any existing institutions. It is an infectious disease which they are to harbour and so they must be isolated; its treatment requires uncontaminated air and sunlight, and so they must stand apart in some county district away from centres of population. And as they must be isolated geographically so, I think, they should be isolated morally from other institutions with which there may be a tendency to associate them. They should be kept free from any taint of pauperism and have no point of contact with the Poor-law. I would suggest, therefore, that not district but county councils, acting singly or in combination, should be charged with the duty of erecting and governing them and that they should be designated "county sanatoria." In the metropolitan district, perhaps, the Metropolitan Asylums Board, that has so efficiently dealt with zymotic disease, might undertake this additional duty. In these county sanatoria (once built) the maintenance and treatment should not exceed 15*s.* a week per head, and that sum many of the indigent class could find for themselves throughout their limited treatment, while a still larger number could find a moiety of it. Then an arrangement might be made by which friendly societies and sick clubs would have the right to demand admission for their members who are consumptive and their treatment for a fixed period at the ordinary rate of maintenance, while collieries, manufactories, and works might by small weekly payments of those employed in them retain a call on a certain number of beds. The contributions of indigent consumptives would go far to maintain these county sanatoria and whatever was required beyond these contributions should be drawn from the county rate. The money thus expended would be profitably invested. The medically certified existence of pulmonary consumption should be the one all-sufficient qualification for admission to these sanatoria, and residence in them should be prolonged until the disease has been cured or bread-earning capacity restored, or until death in hopeless cases. A certain amount of internal classification would be necessary in these county sanatoria, but upon that I cannot now enter. They, like sanatoria for consumptives of every class, should, I think, be under the regular inspection of the medical officer of health of the county. The existence of county sanatoria would surely obviate some of the objections to the obligatory notification of tuberculosis.

I have been speaking this morning exclusively of sanatoria adapted to the treatment of pulmonary consumption, but I need scarcely say that the treatment adopted in these institutions is, with modifications, equally applicable to tuberculosis affecting other organs and tissues. The efficacy of what I may call sanatorial schools planted in the keen but salving air of Margate and of other points on our eastern coast, in tuberculous adenitis or glandular enlargements in children, has been long recognised by the medical profession and highly encouraging results have been obtained at the Institut Verneuil in Brittany by exposing the victims of scrofulous joint disease to the blusterous breathings of the vexed Atlantic. The ratepayer of this country is an Issachar, not couching between two burdens but loaded with innumerable heavy bales that are bending down his strong back, and one hesitates, therefore, to propose the addition of even a small bundle to the pile, but when I suggest special schools in suitable localities and under medical control for the reception of poor children with swollen necks or crippled hips and knee-joints, I feel that I am only recommending a readjustment of the load which will give some immediate ease, and will, in the long run, permanently lighten it. Our Metropolitan Asylums Board and our London School Board have both concerned themselves with the education of the weak-minded. That is a beneficent and useful undertaking and no one grudges the large sums of money that have been expended on it, but it has obvious limitations, for you may gild but you cannot expand "the straitened forehead of the fool" Considering the huge multitudes of poor children in our pestiferous city hutches and hovels who are maimed and lamed for life by the burrowings of the tubercle bacilli in their glands and joints, to say nothing of those who go under and are deposited in batches in our suburban cemeteries; considering further that the children thus afflicted are often, not only of rare physical beauty, but of fine mental fibre—for tubercle is greedy of our fairest and best; and considering that their affliction is in its early stages very remediable, I do not hesitate to affirm that the care and cure of scrofulous children is a more pressing and promising public obligation than the education of the weak-minded. If you deal adequately with all your scrofulous children now, taking them away from their squalid homes and from over-crowded asylums, workhouses, and schools, immersing them in a pure atmosphere and feeding them copiously—*pace* Professor Koch— on milk and meat free from bovine tubercle, with surgical aid and such teaching as is needful to guide the growth of their precocious wits, you will relieve much poignant misery, prevent much decrepitude and pauperism, and materially reduce the amount of weak-mindedness in the next generation. A particular case often brings a truth home to us much better than any general statement. Well, I read in the newspapers only a few days ago the sad story of an inquest on a poor cripple, Leonard Paris, who at 19 years of age found what he called "his lonely, miserable existence" unendurable, and so threw aside his crutch and handled the revolver. From six years old he had suffered from hip-joint disease and although he had been liberally supported by his friends and had had the benefit of treatment in several hospitals, he remained unrelieved, for for four months before his death his temperature was feverish. But although his body wasted, his intellect remained vigorous and clear, as the pathetic letters he left behind him prove, while his sense of deprivation became more and more acute. Hope died within him; at last he wrote: "This time I mean to succeed; better a few moments of pain than an unbearable existence, chained by my merciless, hideous fetters to a disease which I know in my inmost heart to be incurable." The case of Leonard Paris appeals to me with peculiar force because the most brilliantly intellectual youth whom it has ever been my lot to meet, whose Oxford associates predicted for him a triumphant career, when stricken down by a recurrence of tuberculous hip-joint disease, also put out the light with his own hands. Had he and Leonard Paris had the benefit of sanatorial treatment at the outset of their malady there is reason to believe that the tragic issue would have been avoided. Thousands of helpless children around us now, with large, anxious eyes and pallid cheeks, are waiting to have their destiny decided. Is it to be health and gleesome toil or pain and dwining incapacity? Sentiency is the measure of my sympathy. I cannot feel the same pity for a happy jabbering idiot, unconscious of his own defects and with blunted sensibility, that I do for the pretty child who is blemished or racked by disease and cut off from all joyous activity while its emotions and imaginations are preternaturally vivid. I would plead most earnestly for the early, generous, scientific treatment of strumous children. That is one of the ways of preventing phthisis. I do not know what Mr. Cockerton would say to sanatorial schools, but this I do know, that our legislators ought to have no hesitation in granting to local authorities all necessary powers for grappling effectually with tuberculosis in the young.

Literary Intelligence.—Messrs. William Blackwood and Sons have just published a work dealing with British serpents by Dr. G. N. Leighton. We see from the prospectus that the book is the result of years of personal observation. The price is 5s. net.

HOW CAN THE TUBERCULIN TEST BE UTILISED FOR THE STAMPING OUT OF BOVINE TUBERCULOSIS?[1]

BY SHERIDAN DELÉPINE, M.B. EDIN., B.SC. LAUSANNE,
PROCTER PROFESSOR OF PATHOLOGY, OWENS COLLEGE, MANCHESTER.

PART I.—DIAGNOSIS.

A. *Preliminary remarks.*—The question before us is the stamping out of bovine tuberculosis, and more especially how the use of tuberculin can assist us in obtaining this result. The prominence given to tuberculin in this discussion is due to the fact that in our estimation, as well as in that of the most competent authorities, Koch's great discovery gives us the most efficient means of diagnosing tuberculosis during life. In my estimation the keystone of preventive measures must be a reliable and readily applicable method of diagnosis. I might be excused if, after stating this view, supported as it is by the weight of the highest authorities, I made no further attempt to prove its correctness. By following such a course my right to express a definite opinion might be challenged, and I might offer further food for the criticism of those who are still supporting our responsible governments in their attitude of agnosticism. Such an attitude is well expressed by Mr. Walter Long, the late President of the Board of Agriculture, in his 1899 Newcastle speech, in which he is reported to have said:—1. The data were still too *indefinite and wanting in preciseness to justify them in* asking Parliament for great votes of public money or to impose on stock-keepers compulsory measures entailing great loss. 2. They were not yet sure that those measures would be effectual. 3. *The* tuberculin test might be administered so as to render cattle incapable of reaction on a second application of the test, and that might be productive of fraud. 4. People who had studied the question most closely were not agreed as to the conditions under which the test should be applied. 5. The disease was difficult of detection unless one could rely on some such discovery as the tuberculin test. 6. At present too little was known, too much doubted, for Parliament to be justified in imposing upon the country heavy expenditure on wholesale restrictions which would be strongly resisted in many quarters, and which might not do anything effectual for the *extinction of the disease.*[2] Mr. Long's contentions receive support from Schütz's observations.[3] In 1891 this observer tested 66 head of cattle—51 reacted, of these 43 *only* were tuberculous; 15 did not react, *and of these four* were tuberculous. They are also supported by statements made by Professor Bang at the Congrès pour l'Étude de la Tuberculose chez l'Homme et chez les Animaux, held at Paris in 1898.[4] Mr. Walter Long's criticism, which was made some time after the publication of Professor Bang's communication, seems at first sight to express identical views. A careful consideration of Professor Bang's statements will, however, show that they do not entirely justify Mr. Long's conclusions. Professor Bang emphasises the reliability of positive reactions in the great majority of cases; he points out the conditions which may bring about failure of reaction and also the ways by which such errors may be avoided or considerably reduced. He shows also that most of the tuberculous cases which do not react are, firstly, cases in an advanced state of tuberculosis—i.e., those which can be easily diagnosed by other means; *secondly*, cases which have previously reacted and have acquired tolerance; and thirdly, cases in which a slight tuberculosis has been present but in which the disease is becoming arrested. I will be able to show *that such cases should* be no obstacle to proper administration. I wish also to emphasise the fact that although Professor Bang's restrictions may have been used by others for purposes of adverse criticism their author is *not* responsible for this and is undoubtedly one of the earliest and strongest supporters of the use of tuberculin in diagnosis.

We have, on the other hand, statements made by equally reliable and recognised authorities which are entirely favourable to tuberculin. I will not lengthen this communication by a *detailed account of all the records* available, for my purpose will be equally well served by quoting the conclusions which have been arrived at by Professor Nocard and by the Royal Commission on Tuberculosis after a careful compilation of records available and the carrying out of confirmatory experiments. Professor Nocard in 1892[5] gave a very useful summary of the earlier work done soon after the announcement of Koch's discovery of tuberculin, which he summed up as follows: "Tout le monde admet aujourd'hui l'exactitude et la précision merveilleuse des [illegible]

on tuberculosis state: "*We entirely accept these conclusions* and entertain no doubt as to the value of tuberculin provided the test is applied by a competent veterinary surgeon and that the tuberculin is of trustworthy quality."[6]

B. *Criticism of previous experiments regarding the value of tuberculin.*—It is not difficult to account for the differences of opinion which have arisen out of the results of early experiments with tuberculin.

1. The reaction is not simply manifested by any rise of temperature, but, as Nocard and others have frequently observed, this rise of temperature is characteristic only under certain conditions which must be observed in order that the results should be reliable. (*a*) The animal submitted to the test should not be at the time subject to sudden variations of temperature or be suffering from pyrexia. Before applying the test it is therefore necessary to observe the animal for two or three days and to take its temperature morning and evening. Recently driven cattle especially should be tested only after they have been submitted to this preliminary observation. The calving period is also to be avoided. (*b*) In tuberculous animals a characteristic rise of temperature is usually observed between the ninth and fifteenth hours, but it is occasionally, though rarely, observed after the fifteenth hour. (*c*) A slight rise of temperature, not amounting to more than 1° C. above the normal temperature of the animal, cannot be considered characteristic, since healthy animals are liable to fluctuations of temperature capable of producing such a rise. It is therefore desirable to adopt some scale similar to that recommended by Nocard who considers a rise of 0·8° C. (1·4° F.) as having no significance; a rise of from 0·8° to 1·4° C. (from 1·4° to 2·5° F.) as being only suspicious and requiring the confirmation of a further test at the end of a month; a rise of from 1·5° to 3° C. (from 2·5° to 5·4° F.) as characteristic of tuberculosis when the conditions previously stated have been observed. (*d*) It is almost useless to add that no tuberculin should be used which does not come from a reliable source and which has been exposed to loss of activity by long keeping. *The exact dose of each preparation* should be carefully ascertained. Many of the earlier observers have not paid sufficient attention to these precautions. Thus Schütz has considered a rise of 0·5° C. as indicating a tuberculous reaction.

2. Sufficient care has not always been taken to make a thorough post-mortem search for minute tuberculous lesions on animals which had reacted and in the absence of very careful and minute examination it is unscientific to report an entire absence of tuberculosis.

3. The absence of reaction in animals suffering from advanced tuberculosis does not affect the value of the test. This absence of reaction is only what can be expected in the case of animals which are already saturated with the products of the tubercle bacillus. This state is probably analogous to the state of tolerance produced by frequently repeated doses of tuberculin. But when cows have reached such a stage of tuberculosis their state should be obvious to a competent veterinary surgeon, and as most of these animals would be suffering from advanced phthisis the clinical diagnosis could be confirmed by the bacteriological examination of mucus obtained by swabbing the pharynx according to the method recommended by Grellier.[7] (To excite *secretion pilocarpine*, from 25 to 30 centigrammes, may be previously injected.)

4. The absence of reaction in the case of animals in an early stage of tuberculosis will, I think, be found to be very rare when the test is properly applied. The most remarkable feature of the tuberculin test is the power which it gives to detect extraordinarily small lesions, and it is this property which, I think, renders it so specially suitable as a basis for preventive methods and will allow such methods to be carried out economically—i.e., before infected animals have lost their value on the meat-market. But even if a few escaped it is obvious that early tuberculous lesions could hardly be a source of infection in other animals and that under a regular and thorough system of inspection these animals would be detected before they had become a source of danger to other animals or to man.

5. With regard to the tolerance acquired by cattle which have been tested several times I can best indicate to what an extent this might be a source of difficulty by giving the results of some experiments made for the Cheshire County Council by Mr. Laithwood, chief veterinary inspector of the county. I was able to follow these experiments closely, being engaged in another branch of the same investigation. In the space of 80 days several cows were tested five times at variable intervals with the following results (Table I.).

TABLE I.—*Effects of Testing with Tuberculin Repeated at Short Intervals.*

Reference No. of cow.	First testing.	Second testing, 45 days after first.	Third testing, 13 days after second.	Fourth testing, 14 days after third.	Fifth testing, 12 days after fourth.	Result of post-mortem examination and remarks.
5	?	?	–	?	–	Case of distomatosis; temperature irregular.
24	+	+	+	+	–	Advanced tuberculosis.
32	+	+	+	+	?	Slight tuberculosis.
37	+	+	+	+	–	Slight tuberculosis.
41	+	+	+	+	–	Advanced tuberculosis.
42	+	+	?	+	–	Advanced tuberculosis.
27	+	+	Not tested.	+	Not tested.	Advanced tuberculosis.
35	?	–	Not tested.	–	Not tested.	Healthy.
51	+	+	In calf; not tested	+*	...	Tuberculosis slight.

* Tested later than the others.

Three of the cows which had ceased to react were found to be still in the same state 35 days after the last test. ? indicates that the reaction was doubtful.

It was only at the fifth injection that the tuberculous cows all ceased to give a reaction, and this fifth injection had followed the fourth, third, and second testings at intervals of only 12, 14, and 13 days respectively. Nocard had previously obtained more carefully tested results showing that tolerance to tuberculin is not so easily produced as has been stated.

Fear of fraud cannot be considered a very sound argument against the use of a good method.

C. New experiments.—Having shortly referred to some of the evidence already available I must now record the results of experiments which have been conducted under my supervision since 1897 and in which an attempt has been made to observe all the precautions necessary to avoid the fallacies which have been previously discussed. I will also take advantage of the extensive investigation carried out in Aberdeen on behalf of the University Department of Agriculture in 1899. As a result of a conversation which I had with him, Mr. Gair Ashton, M.P., in 1897 decided to test practically the possibility of stamping out tuberculosis from the herd kept on his estate at Ford Bank. The probable cost of the experiment which I fully explained did not deter him, and with great liberality and public spirit he gave me the means of obtaining all the information which I could obtain from such an experiment. The small herd kept at Ford Bank consisted in 1897 of 21 cows, bullocks, heifers, and calves, several of which were tuberculous. The problems before us were, first, to stamp tuberculosis out of Ford Bank; secondly, to estimate the cost of this radical procedure; and, thirdly, to keep the new stock free from tuberculosis. Briefly speaking, these experiments were conducted as follows. All the stock on the farm was tested with tuberculin from the Institut Pasteur by Mr. Locke, assisted at first by Mr. King, the corporation chief veterinary inspector, and afterwards by Mr. Holburn, Mr. King's successor. The test was applied with all the precautions which I thought necessary and which I have previously indicated. In all cases the animals were kept under observation for two or three days before testing and their temperature was taken at least three or four times. After the injection of tuberculin the temperature was taken, with few exceptions, four times between the ninth and twentieth hours at intervals of three hours. The animals which did not react were at once transferred to recently disinfected sheds. Those which reacted were speedily sent to the abattoir. The carcasses of slaughtered animals were examined carefully at the abattoir by Mr. Holburn and the lesions found were carefully recorded. In doubtful cases the organs or parts of organs were referred to me for further investigation. The price obtained for each carcass was also noted. Each animal previously to being slaughtered was valued by an independent expert. All the calves were kept isolated from the first and were fed on boiled milk. No attempt was made to separate the calves of tuberculous dams from the others, of which there were very few. The stables which had been occupied by tuberculous cattle were disinfected thoroughly with chlorinated lime solution and then they were whitewashed. To fill the gaps made in the old stock new stock was bought subject to the tuberculin test, the animals being kept in a separate shed previously to the application of the test. All animals found to react were returned to the seller and only those which did not react were added to the old stock. This was done in order to ascertain the safety of relying on the tuberculin reaction as a basis for contract. The milk of none of the tuberculous cows was again used on the farm without being boiled, although there was no evidence of tuberculosis of the udder in any case. Finally, owing to Mr. Ashton's change of residence, all his cattle were sold by auction and a record was kept of the prices obtained for each animal. Shortly speaking, the results of the tests were as follows in the case of cattle which I have been able to keep sufficiently long under observation. (I have excluded all animals which after being tested once were lost sight of.) *Definite reactions:* 48 out of 49—i.e., nearly 98 per cent. The doubtful reaction gave place to a definite reaction on the second trial within three months, so that the failure was not a permanent one. *Positive reactions:* 19 out of 19 proved to be correct—i.e., 100 per cent. *Negative reaction:* 28 out of 29 proved to be correct at once—i.e., 96·5 per cent. The tuberculous cow which did not react had newly calved; this error was corrected within three months by re-testing. I believe that a method which gives such results may be considered as perfect as any other method of diagnosis can ever be expected to be.[8]

I am fortunately in a position to avail myself of the results of a later investigation bearing on a much larger number of animals examined under conditions such as may be easily observed in practice. I had opportunity to discuss with Professor D. J. Hamilton the conditions under which this set of experiments was carried out and I am fully satisfied that as far as they go the results may be received as absolutely reliable. I feel, however, that, owing to the facts that the temperature of the animals was taken only once before the test was applied and only between the tenth and thirteenth hours after the injection, the value of tuberculin was tested somewhat more severely than was necessary. It is not possible to reproduce here the tables of results given in the report of this experiment published in 1899 by the Department of Agriculture of the Aberdeen University.[9] The authors explain in this report that by arrangement with important butchers and cattle-owners they have been able to test a large number of cattle which were intended for slaughter, generally on the farm before removal, but when this was impossible the test was applied in the byre connected with the slaughter-house after the animals had been kept there for 24 hours. It will be obvious, therefore, that in the second group of cases the test was applied under conditions not altogether favourable to success. The main conclusions of the authors regarding the value of tuberculin are summed up as follows by themselves: "1. Our experience confirms the generally accepted opinion that tuberculin loses its virulency when kept for any length of time. 2. When used with care and under proper conditions tuberculin is a reliable diagnostic of tuberculosis in cattle, except (*a*) when the tubercular lesion is minute, or (*b*) when the disease has become generalised, especially in the case of aged and emaciated animals." The authors sum up these results in four tables giving a detailed account of the age of the animals tested, of the temperatures observed, and of the lesions found in the carcasses after slaughter. I have prepared on the basis of their own records the following table (Table II.).

---

[8] See second part of this paper for the other results of this experiment.

[9] Report on an Investigation with regard to the Value of Tuberculin as a Test of the Presence of Tuberculosis in Cattle. By J. McLauchlan Young, F.R.C.V.S., and J. S. Walker, M.B., D.P.H., Aberdeen University, 1899.

TABLE II.—*Analysis of the Sources of Failure in the Aberdeen Experiments.*

—	Number tested.	Age.	Tuberculin reaction.		Tuberculosis found post mortem.	Error in tuberculin reaction.	
			−	+		+	−
						Per cent.	Per cent.
Heifers ...	60	1½ to 2 years.	54	6	10	0·0	6 6*
Bullocks ...	100	2 years.	80	20	24	0·0	5·0†
Bulls	3	3 years.	2	1	1	0·0	0 0
Cows	77	Average 7½ years.	52	25	42	0·0	32 6

* Corrected 1·6 per cent. † Corrected 2·5 per cent.

NATURE OF CASES IN WHICH ERROR WAS OBSERVED.

Heifers.—Nos. 28 and 30: Bad tuberculin used. No. 31: The syringe leaked; quantity injected unknown. No. 60: The dose was possibly too small; this is the only error not fully explained by experimental accidents. This reduces the percentage of failures to 1·6.

Bullocks.—No. 3: The only lesion was a *fibrous* tubercle in the lung. No. 7: There was a rise of 1° F. The animal was not well; this is not a negative but a doubtful reaction. No 19: There was a minute calcareous tubercle in the mesenteric glands, tubercle bacilli were found, but the process was apparently becoming quiescent. It is doubtful whether any of these cases is a complete failure; two cases may be accepted as such. This reduces the percentage of failures to 2 5.

Cows.—Nos. 5, 6, 7, 19 and 33: In all these [illegible]

We may safely exclude from this table all the results which are vitiated by experimental faults clearly admitted. On the other hand, we must retain those results which though of doubtful value may be accepted as necessary defects which would occur under ordinary circumstances. After excluding from the animals one the age of which was not stated and five which cannot be considered as having been properly tested (in two cases old inactive tuberculin was injected; in another the syringe leaked and the quantity was not known; in two others it was doubtful whether there was active tuberculosis or not) I have constructed tables bringing out facts which had not been previously paid sufficient attention to and which corroborate my previous experience in Manchester (Table III.).

Even if the five cases which I have excluded on good grounds from the group of animals under eight years of age were retained in that group the total number of errors would have been nine out of 209 tests, an error equal to 4·3 per cent. I should state also that all the positive tests were found correct, whilst of the nine cases in which a negative reaction was misleading seven were affected with extremely localised tuberculosis arrested or nearly arrested, and only two were suffering from pulmonary tuberculosis and might have been a source of infection. In this group, therefore, the amount of serious and material error amounted to two out of 209, or less than 1 per cent. With regard to the second group of aged cows they were all in an advanced state of tuberculosis and their state would have easily been recognised by clinical examination.

I will show later that under a proper system of inspection tuberculosis should never reach such a degree as to render tuberculin useless as a method of diagnosis. It may be interesting to note that similar experiments conducted in 1891 in the Duchy of Baden by Lydtin, according to the same plan as that adopted in Aberdeen, yielded the following results. Of 110 head of cattle there was negative tuberculin reaction in 70, in none of which were tuberculous lesions found post mortem; there was positive tuberculin reaction in 39, and tuberculous lesions were found post mortem in 37 of them; and there was doubtful reaction in one animal. In this experiment the negative reactions were free from error. The errors in connexion with the positive reactions were two in number, but as no precaution appears to have been taken to allow the animal to rest before the injection of tuberculin, and as perhaps not sufficient attention was paid to deep-seated lymphatic glands, the results obtained were remarkably accurate.

TABLE III.—*Influence of Age and Disease on the Results of the Tuberculin Test.*

—	Number of animals giving a definite reaction.	Tuberculin reaction.		Tuberculosis found post mortem.	Total number of tuberculous animals.	Error on − reaction.	Error on + reaction.

Totals for cows above eight years of age	25	22	3	19	76·0	16 = 76%	0

The results of these three sets of experiments which bear upon a total of 408 animals leave, I think, no room for doubt as to the efficiency of tuberculin as a diagnostic agent when it is properly used. The amount of error attributable to failure of the test is very small; indeed, it is trifling when compared to the errors which are inherent to most methods of diagnosis, many of which are, nevertheless, used as a basis for administrative procedure. To the direct evidence which I have already given I may add some indirect evidence which I have collected in the course of my investigations on cow's milk as a source of infection. In the course of six years nearly 2000 samples of milk have been examined in my laboratory; of these samples over 500 were from single cows. I am greatly indebted to the Manchester Sanitary Committee, and especially to Dr. Niven, for the facilities which have been given to me for collecting the information which I wished to obtain; to Mr. Holburn, the chief veterinary inspector; and to Mr. Lloyd, the veterinary inspector attached to the Sanitary Department, for supplying me with all the material I required. I have also to acknowledge similar help received from Mr. Tattersall, the medical officer of health of Salford, and his veterinary inspector, Mr. Fordham. The following table records some of the data which I have thus obtained. The smallness of the numbers is undoubtedly disappointing considering the amount of trouble taken, but the absence of any discordant result renders these figures, small as they are, very significant. Most of the 505 cows the milk of which was examined separately had suspicious udders. A reliable record of the effects of the tuberculin test was obtained in 50 cases only. The following table (Table IV.) shows the effects of inoculation of guinea-pigs with the milk of these 50 cows.

TABLE IV.—*Information Collected in Connexion with the Examination of Milk from Single Cows with Diseased Udders since 1896.*

Year.	Total number of cows examined.	Total number in which a record of the tuberculin test was obtainable.	Number of cows giving a positive reaction.	Number of cows giving a positive reaction and the milk of which was tuberculous.	Number of cows giving a negative reaction.	Number of cows giving a negative reaction and the milk of which was tuberculous.	Doubtful reaction.	Milk tuberculous.
1896–97	30	15	12	5	3	0	—	—
1898	4	0	—	—	—	—	—	—
1899	173	14	12	1	2	0	—	—
1900	208	19	12	2	5	0	2	0
1901	90	2	0	0	0	0	—	—
Total	505	50	36	8	10	0	—	—

This evidence shows that none of the cows giving a negative reaction with tuberculin yielded tuberculous milk. On the other hand, all those cows which yielded tuberculous milk gave a positive reaction.

PART II.—ADMINISTRATION AND FINANCE.

A. Methods which have been recommended for the prevention of tuberculosis in cattle.—When one reviews the various methods which have been recommended, and sometimes carried into execution, for the purpose of checking the progress of tuberculosis, one is struck with the fact that most of these measures had for their chief object the protection of the consumer of tuberculous products, more especially meat and milk. The measures provide the means of controlling to a certain extent cattle which have become tuberculous, but they do not make, in my opinion, any adequate provision for the eradication of existing tuberculosis or for the prevention of the spread of the disease among cattle. I think that the chief causes of the failure of the legislation which has been proposed so far in various countries have been the following. 1. Nowhere has the use of a sufficiently accurate method of diagnosis been made the basis of the measures taken. Tuberculin has been recommended, but option in favour of clinical methods has almost invariably been allowed. This, as I have shown, has for effect to allow a large number (probably from 80 to 90 per cent.) of tuberculous animals to remain undetected. On the other hand, if the use of tuberculin had been made compulsory as a basis of action with regard to cattle under seven or eight years of age, not more than 2 or 3 per cent. would have escaped for a time but would have ultimately been discovered on re-injection. (The proportion of aged cattle kept on farms is gradually diminishing.) 2. With the exception of the short and necessarily incomplete trials which have been made by the State of Massachusetts and the Belgian Government those methods have been partial and not general, so that what good was obtained in one farm or district has been counteracted by the absence of precautions in a neighbouring farm or district and by the shifting of tuberculous cattle from districts under control to those not supervised. 3. When slaughter of tuberculous animals has been resorted to this has generally been done without discrimination, and the necessary compensation has become so costly as to be prohibitive. These have, in my opinion, been the chief causes of failure, and I have therefore attempted to find if it would not be possible to discover some solution of these difficulties.

B. Experimental stamping-out of tuberculosis in a small herd.—1. I have shown by the Ford Bank experiment how, by a careful application of the tuberculin test, disinfection of premises, and thorough disinfection, it is possible in the short space of one year to replace entirely a highly tuberculous stock by stock free from tuberculosis remaining on the original premises. This stock remained entirely free from tuberculosis during a second year. To make this clear I may sum up the results in the following way: May, 1898.—Old stock: 12 milch cows and heifers, 11 tuberculous; three bullocks, two tuberculous; and six calves, all free from tuberculosis. Total, 21 animals, 13 of which were tuberculous, or 61·88 per cent. February, 1900.—New stock, including old stock which had not previously reacted: 20 milch cows and heifers,[10] none of which were tuberculous; one bullock not tuberculous; and nine calves born since the beginning of the experiment, none of which were tuberculous. Total, 30 animals all free from tuberculosis.

2. In my experiments it has been impossible to test the effects of general measures except by the rigid exclusion from the estate of new cattle which had not passed the tuberculin test. This was done by making a negative tuberculin reaction a *sine quâ non* condition to the introduction of any fresh cattle. 24 cows or heifers, apparently healthy and specially selected, were offered to Mr. Ashton's steward under these conditions. They were all isolated and tested with the following results; of 11 cows five years of age or more six reacted, and of 13 cows or heifers from two to three years of age one reacted, giving a total of 24 animals, seven of which reacted.

3. The financial aspect of the question, which from a scientific point of view is not the most important, is probably, from the practical and administrative sides, the chief difficulty which has to be overcome before satisfactory preventive measures can be put in force. The Ford Bank experiment was therefore conducted in such a way as to yield as much information as possible on this point. It will, however, be obvious to those who are acquainted with farm management that it was impossible for Mr. Ashton to have the experiment conducted as economically as it could have been by a practical farmer. Owing to the conditions of a farm kept in pleasure-grounds the Ashton experiments must be considered as indicating the maximum cost of preventive measures. This, however, does not in the least diminish their importance. In May, 1898, the approximate value of the old stock, which consisted chiefly of 21 well-bred Yorkshire Shorthorns (not pedigree cattle), was £262.[11] 13 of these gave a positive reaction at the first testing with tuberculin and were slaughtered at once—viz., eight cows, three heifers, and two bullocks, which were all found post mortem to be tuberculous. Except in one case all the viscera had to be condemned; in addition to this, one whole carcass was condemned on account of generalised tuberculosis, and the half of another was also found to be unfit for food. The sum realised for the carcasses was £159 4*s.* 8*d.*, and the value of the remaining stock was £48 10*s.* (total, £207 14*s.* 8*d.*); the actual loss was therefore £54 5*s.* 4*d.*, to which must be added the veterinary charges, which amounted to £10, making in all £64 5*s.* 4*d.* There was also a serious loss of dairy produce which was due to the immediate slaughter and which would not have occurred to the same extent had arrangements been made to slaughter the diseased cows only at such time when they were in a proper condition and it had been possible to replace them rapidly. (The milk of diseased cows should, of course, be always sterilised before use.) The next step taken was to replace the diseased stock. The shippons having been thoroughly cleansed and disinfected new stock was bought subject to the tuberculin test—that is to say, the cows were kept at Ford Bank for about a fortnight, during which they were tested, and only those not reacting were kept. A fee of £3 was paid to the seller as a general consideration for the trouble caused by this arrangement. But I think he found further compensation in the prices which he charged for the cattle sold under these special conditions.

The experiment carried out by the Cheshire County Council may be compared with advantage with the Ford Bank experiment. This important experiment was conducted on very much the same lines as the Ford Bank experiment, but about one year later The cattle tested at the county council farms at Worleston and Holmes Chapel numbered over 70 The results were very similar to those obtained at Ford Bank.

---

[10] The average age of these cows was higher than in the case of the old stock.

[11] The cattle were in these experiments valued by an independent expert, the value of whose opinion is generally recognised in the district.

A general consideration of the results obtained at Ford Bank, Worleston, and Holmes Chapel leaves no doubt as to the value of tuberculin as a diagnostic agent—that is to say, as far as the positive reactions are concerned This is a matter of great importance from an administrative point of view, for tuberculin could hardly be employed for administrative purposes if it were found that many non tuberculous cows gave a reaction similar to that given by tuberculous cows With regard to the value of the negative reactions I have shown in the first part of this communication that by proper attention to certain conditions they are also quite reliable It is also evident that the immediate loss caused by indiscriminate slaughter of all tuberculous animals is very considerable Valuable stock being excluded, there was a loss of £52 11*s* 6*d* on the nine tuberculous animals from Worleston, that is, a little more than £5 16*s* per head[12] At Ford Bank the loss on the 13 animals slaughtered was £64 5*s* 9*d*—i e, a little under £5 (veterinary charges included) On the 22 animals from both places the average loss was nearly £5 7*s* per head

C Influence of age on the losses caused by tuberculous—In order to obtain information on this point I divided all cattle into five groups (1) five years of age and over, (2) three years and up to five years exclusive, (3) two years and up to three years, (4) one year and up to two years, and (5) under one year Then I found for each group the number of tuberculous animals, their estimated value under ordinary circumstances as dairy stock, and their value as meat after they had been slaughtered on account of tuberculosis and thoroughly inspected at a public abattoir by competent veterinary inspectors[13] I cannot give here the details of these calculations which I have summarised in the following table (Table V)

TABLE V—*Showing Losses caused by Slaughter of Tuberculous Cattle of Various Ages*

Ford Bank

—	Percentage of cows and heifers tuberculous	Estimated value of 100 animals before testing	Loss on 100 such animals after slaughter of tuberculous ones	Percentage loss on capital
	Per cent			Per cent

It is evident from these figures that if herds are to be kept free from tuberculosis by a method which will not cause unnecessary pecuniary loss this must be done by removing all animals which have become tuberculous before they have reached their third year Before that date the slaughter of tuberculous animals does not involve any serious loss to the farmer, at a later period the loss becomes very serious more especially in connexion with cows between the third and fifth year, when they have reached their greatest value as milkers With regard to bullocks the problem is simpler, but it is equally evident that all tuberculous animals should be isolated before they are two or three years of age and then slaughtered as soon as they can be profitably sold to the butcher If all the tuberculous stock over three years were eliminated from our herds it would be quite easy for the farmer, assisted by competent veterinary inspectors, to keep his stock ever after practically free from tuberculosis without any serious expenditure to himself

D Practical experiment to test the relative meat value of tuberculous and non tuberculous cattle under two years of age—In order to test whether the foregoing conclusions were correct Mr Gair Ashton generously consented to bear the cost of a new experiment This I will call the second Ford Bank experiment Ten barren heifers not over two years of age were to be bought by the steward at a fair or from a cattle dealer They were to be selected in the usual way on the basis of their external appearance and estimated value and *not subject to the tuberculin test* After a few days' rest they were to be tested and the animals reacting were to be entirely separated from those non reacting This young stock was then to be fattened and when ready for the butcher their value as live stock was to be estimated by an expert The animals were then to be tested again and slaughtered at the Manchester abattoir and their carcasses were to be thoroughly inspected by Mr Holburn the chief veterinary inspector, who kindly undertook to report upon them The carcasses were then to be offered for sale at the meat market Mr Jones[14] was to keep a complete account of the cost of agistment, special feeding, and testing, as well as of the amount realised after slaughter By this experiment I hoped to obtain definite answers to the following questions 1 Old tuberculous cattle being removed, what would be the cost of keeping the purified herds free from tuberculosis by the slaughter of young tuberculous animals during the first few years following the first application of the stamping out measures? 2 What loss, if any, would be incurred by the selling to the butcher of young tuberculous carcasses? 3 Would the tuberculin reaction prove a practical basis for the carrying out of the method which I had suggested? The second Ford Bank experiment was carried out according to the general plan indicated above Circumstances, however, prevented our waiting for a time favourable to purchase on suitable terms It was also found impossible to select the best time for fattening and selling The 10 heifers were tested a second time on Nov 15th, with the result that the six which reacted in July reacted again and the four which did not react continued to give a negative reaction They were then sent to be slaughtered at the Manchester abattoir on Nov 22nd Their carcasses were there examined by Mr Holburn in the presence of Mr Locke who had tested the cows, and Mr Jones Mr Jones reported to me as follows In each case Mr Holburn was able to say which of the animals had reacted *without any reference to the testing notes*, it was therefore perfectly clear that tuberculosis was present in all those animals that had reacted In no case was it necessary to condemn any part of the carcass' The original cost of the 10 heifers *plus* the cost of keeping them for four months and fattening them had been £120 11*s* 6*d* The total sum realised after slaughter was only £90 12*s* 2*d* There was therefore a loss of about £3 per head This loss was not so great as that borne in connexion with cattle of all ages, which was over £5 per head; but in my opinion there should have been no loss at all, in fact I expected a profit There are, however, certain features of the experiment which account for the failure 1 The cattle had been bought irrespectively of the conditions of the market and as I understand too late in the season 2 The steward who bought the cattle had not much experience of the value of live stock this was the opinion of two experienced men who warned me before the conclusion of the experiment of the fallacy which this might introduce It was also unfortunate that two heifers in calf should have been bought, as such animals whatever their value might be in life, were not (before calving) suitable beasts for the meat market As a speculation the experiment was not a success, but considering the mode of purchase and selling it could not be expected to be a sound transaction The total sum paid for the 10 animals in July was £96 Their total estimated value as living stock in November was £109 10*s* Their total cost *plus* the cost of keeping and fattening, was in November £120 11*s* 6*d* If from this total expenditure the sum of £5 spent for the carrying out the test is subtracted there remains still a total expenditure of £115 11*s.* 6*d.* It is therefore obvious that even if tuberculosis had been out of the question there would have been a loss in the *transaction* due to some error in the purchase. It is also possible that too much had been spent on special feeding—£1 1*s.* per head. The experiment has not therefore yielded the same results as it would have yielded in the hands of an experienced and skilful farmer. But although it was not successful with regard to management it has nevertheless given very *important results* with regard to the relative value of the flesh of tuberculous and non-tuberculous young cattle. The following table (Table VI.) of results gives the value obtained for eight of the 10 carcasses (two of them were *sold* together and it was impossible to ascertain afterwards their separate value).

---

[12] A later estimate based on the losses caused by the slaughter of 19 tuberculous [illegible] £7 7*s* per head This would [illegible] up to £6 [illegible] per head [illegible] valuable animals [illegible] of proportion to the value of their carcasses; the loss on such animals should always be considered separately)

[13] Information regarding the age of cows which cannot be found in the Cheshire County Council Report I have obtained through the courtesy of Mr P P Ward the organising secretary to the Technical Instruction Committee

[14] Mr Jones had charge of the cattle and dairy at Ford Bank

Averages per head £8 14*s.* 10*d.*	£7 13*s.* 7½*d.*	£7 12*s.* 6*d.*

The same animals were also valued before being slaughtered, and it was found that during life they stood in the same relation as their carcasses did. The same prices had been paid originally for the three tuberculous heifers in Group A and the three healthy heifers in Group C. There seems, therefore, no evidence showing that *a moderate amount of tuberculosis depreciates* the meat value of young carcasses. As a matter of fact, in this case better value was obtained for tuberculous carcasses than for those which were free from the disease—a fact to which I will have to allude again. This matter being one of great importance I thought it desirable to obtain an independent opinion from Mr. Holburn who had inspected the carcasses. I therefore asked him to give me without any reserve his views on the results we had obtained. With his permission I reproduce the answer :—

Markets Department, City Abattoirs, Water-street, Manchester.
Jan. 23rd, 1900.

DEAR PROFESSOR DELÉPINE,—In answer to your inquiry as to the market value of Mr. Ashton's experimental cattle and as to whether there was any difference in the conditions of those animals that reacted to the tuberculin test from those that did not react as regard their saleability, I feel quite confident in expressing the opinion that as regards their carcass value those animals that reacted came out as well as—in fact, one or two of them a little better than—those that did not react to the test.

ALFRED HOLBURN, M.R.C.V.S., Chief Inspector.

This valuable statement is in complete agreement with the results which I have recorded above. It is, however, evident that it would have been preferable to use animals two and a half or three years old for the experiment The age which I had fixed was two years, in order to avoid cows in calf, but this complication was not successfully avoided. Taking everything in consideration it seems, therefore, evident that if young tuberculous cattle be properly prepared for the meat market there could not be a more profitable or convenient way to dispose of them than by that method. It is equally certain that at no other period in their life could their flesh be utilised with less danger to public health [15]—a danger which should disappear entirely if private slaughter-houses were entirely abolished and all the meat submitted to thorough inspection as it is in the Manchester city abattoirs.

E. Disposal of the milk of tuberculous cows.—Whilst I consider it advisable to deal with young stock under three years of age as rapidly as possible, I think that in the present state of things the indiscriminate slaughter of all tuberculous animals above that age would be attended with considerable and unnecessary losses. Only cows in an advanced stage of tuberculosis, showing evidences of wasting or of tuberculosis of the udder, should be slaughtered without delay. They are serious sources of infection and the longer they are kept the less their value becomes, if they retain any at all.

With regard to the cows which are not in an advanced stage of tuberculosis it is desirable that those in milk should be fattened only after lactation had ceased or had been caused to stop. As it is impossible to foretell how soon the udder of a tuberculous cow will become diseased it would be wise to consider *the milk* of all tuberculous cows as suspicious. It should therefore be sterilised before being used. With the object of finding how this suspicious milk could be utilised I made two years ago a number of experiments. I found that it was not easy to obtain butter free from abnormal taste with cream which had been heated for a few minutes to a temperature exceeding 75° C., and that contrary to results obtained by some other observers complete safety could not be obtained by the heating of cream up to 85° C. for 15 minutes. Some of the results obtained are given in Table VII.

TABLE VII.—*General Results of Experiment on the Sterilisation of Cream.*[16]

—	Temperature.	Duration of exposure after the temperature indicated had been reached.	Results of inoculation of guinea-pigs with equal quantities of treated and untreated tuberculous cream.
First set of experiments.	74° C (165° F.)	30 minutes.	Tuberculosis slight and delayed, well-marked after three weeks.
	76° C. (169° F.)	10 ,,	Tuberculosis slight and delayed, well-marked after three weeks.
	82·5° C. (180° F.)	5 ,,	Tuberculosis nearly normal.
Second set of experiments.	85° C. (185° F.)	15 ,,	Tuberculosis considerably delayed (two months).
	70° C. (158° F.)	45 ,,	Tuberculosis delayed but well-marked after three months.
	65° C. (149° F.)	360 ,,	No tuberculosis after three months.
	65° C. (149° F.)	180 ,,	Slight. tuberculosis after one month.
	65° C. (149° F.)	60 ,,	No tuberculosis after one month.
Controls.	—	—	Well-marked tuberculosis after three weeks.

No reliance should be placed on pasteurisation of cream at temperatures up to 85° C. for the times indicated in the above table. I regret to say that in a previous paper I had expressed the opinion that a lengthened exposure of cream to a temperature below 85° C. would probably be sufficient to destroy the tubercle bacilli. I stated, however, at the same time, that I had not completed the experiments which I was making with the view of confirming the experiments of other observers.[17] In my opinion, therefore, the *milk of all tuberculous cows should be boiled before it is used.* I do not venture at present to suggest any special means of utilising this milk; all I wish to do is to express a *warning against an implicit belief in the statements which have been made regarding the ease with which the milk of tuberculous cows can be rendered innocuous.*

F. Innocuousness of tuberculin inoculations.—It has been frequently stated that the use of tuberculin was detrimental to milch cows. Not being able to investigate this matter personally I have asked Mr. J. Jones to give me his impression upon the effects which our experiments had had on the dairy cows kept at Ford Bank. The following was his answers : "The quality of milk from tested stock was all that could be desired. I do not consider testing to be at all detrimental to dairy stock in any way if carefully done." Knowing that Mr. Walter W. Law of Briarcliff Manor, New

---

[15] I do not wish to convey by this the impression that the consumption of meat from tuberculous cattle is attended with much danger.

[16] I wish to acknowledge here the cordial assistance which I received from Dr. E. J. Sidebotham and Dr. F. J. H. Coutts in the carrying out of these experiments, some of which lasted for a considerable time.

[17] See Veterinarian, July and August, 1899.

York, had for some years past determined to clear his extensive herds from tuberculosis, and had had for this purpose his cows repeatedly tested with tuberculin, I asked him to supply me with some information on the effects of the testing on healthy cows He had the great kindness to forward my request to Professor Leonard Pearson of the University of Pennsylvania who inspects biannually the Briarcliff Farms dairy herd This herd is composed of over 600 "thoroughbred or high grade" Jersey cows Professor Pearson replied as follows —

> University [illegible] erinary Medicine,
>
> DEAR SIR,—I [illegible] itted by Professor Delépine regard[illegible] althy cows I would [illegible] of [illegible] e to [illegible] est [illegible] per [illegible] ss [illegible] e at [illegible] ove [illegible] ear [illegible] and [illegible] ws) [illegible] Mr [illegible] in [illegible] n of [illegible] is a [illegible]
>
> [illegible]
>
> To Walter W Law, Esq, Briarcliff Manor, New York

G Disposal of valuable stock.—I would urge that pedigree cattle in which tuberculosis has not produced serious lesions should be carefully isolated and watched, that these animals should be used for breeding purposes and slaughtered as soon as possible after they have sufficiently fulfilled the purpose for which they are kept In the event of the disease affecting their general health they should be slaughtered without further delay

H Market value of living tuberculous animals.—Before [illegible] I [illegible] the question which [illegible] out Early tuber[illegible] the appearance of young and middle aged stock, is often associated with all the external appearances of flourishing health Many tuberculous cows are exceptionally good milk producers They have often a very good market value during life It is not therefore easy to persuade the farmer that tuberculosis may be a serious source of loss to him He does not consider it a matter of importance to discover whether a cow is tuberculous or not so long as the animal is a good milk producer or does not lose flesh It is not denied that a herd affected with tuberculosis is liable to greater depreciation than a herd free from tuberculosis, but it is urged that in the present state of things the loss of capital involved by the removal of tuberculous cattle would be so great that the ultimate benefit would not be sufficient or obtained soon enough to prevent ruinous losses It is therefore stated that farmers cannot be reasonably expected to adopt measures which would be contrary to their own interests If the matter could be considered in the light of a commercial transaction affecting only one generation of speculators having no responsibility towards their country or humanity the above argument might be considered sound It is, however, the duty of the State to see that the present generation does not sacrifice for its own benefit the patrimony of future generations, thereby doing great harm to the country It is also the duty of the State to see that any condition of things which tends to perpetuate the existence of a disease which is so detrimental to man as well as to the lower animals is checked as speedily as possible Even if the financial argument against the stamping out of tuberculosis were as sound as it appears to be it does not prove that farmers are justified in remaining passive If through ignorance they have allowed the evil to grow beyond control they cannot consider this a valid excuse for not doing their duty as soon as they know what their duty is The fact, however, that the carrying out of this duty towards the State would mean complete ruin in the case of many small farmers whose welfare is also of importance to the whole country clearly shows that a part of the losses caused by the stamping out of tuberculosis should be borne by the State.

CONCLUSIONS.

1 Tuberculin is an almost infallible test of the presence of tuberculosis in animals under seven years of age when this fluid is used with proper care In older cattle clinical methods are more reliable than the tuberculin test as used at present. (The use of larger doses than the usual ones may, however, be resorted to with advantage in these cases) 2. It is possible by the use of tuberculin and thorough disinfection of cattle-sheds to stamp out tuberculosis from a herd in *the course of one year* 3 *Cases of infection* which may accidentally occur after this preliminary removal of tuberculous cattle can be easily and economically detected by the periodical use of tuberculin 4 Tuberculous animals between two and three years of age can be disposed of on the meat market without serious loss 5 The slaughter of cows in calf or of milch cows not in an advanced stage of tuberculosis involves a serious loss to the farmer, and so long as tuberculosis is as prevalent as it is at the present time it is doubtful whether the measures necessary for the extirpa*tion of tuberculosis can be left to private efforts without* State help 6 To remove the chief sources of infection immediate slaughter should be resorted to in the case of all animals in a state of advanced tuberculosis, and of all cows with tuberculosis of the udder 7 Milch cows and cows in calf in which tuberculosis is not very advanced should be isolated and slaughtered only after they have been suitably prepared for the butcher The milk of tuberculous cows should invariably be sterilised by boiling 8 Valuable breeding animals free from advanced tuberculosis or tuberculosis of the generative organs should be isolated, *they* can be kept *for a time* for breeding purposes provided the calves are isolated and fed on sterilised milk 9 Measures which do not provide for the removal of all tuberculous animals from a district, for the disinfection of all cattle sheds in that district, for the periodical testing of all the animals within the district, and which do not give the means of preventing the importation of tuberculous animals cannot be expected to yield satisfactory results.

MEASURES RECOMMENDED.

On the basis of these conclusions I feel justified in recommending once more the general measures which I have advocated on several occasions during the last few years These may be summed up as follows —1 Division of the whole country into a number of well-defined administrative areas each provided with an efficient staff of inspectors 2 Marking and registration of all cattle for purposes of inspection and notification (This would, of course mean the inclusion of tuberculosis among the recognised contagious diseases) Systematic periodical inspections of herds and cowsheds within each administrative area. Testing with tuberculin of all cattle. 3 Isolation of all tuberculous cattle Disinfection of sheds which have been occupied by tuberculous cattle 4 Immediate slaughter of all cattle in an advanced state of tuberculosis (including all cases of udder tuberculosis) 5 Fattening of all animals not in an advanced state of tuberculosis for the meat market All cattle should be slaughtered in *public abattoirs* so as to insure *thorough meat inspection* 6 Compensation during one year or two for losses incurred by owners of cattle, except in cases regarding which there had been gross or culpable neglect After this *transitional period of compensation* the presence of a case of advanced tuberculosis in a cowshed to render the owner liable to a penalty 7 Testing of all cattle brought into the area so as to prevent the introduction of fresh sources of tuberculosis No cattle above six years of age to be imported 8 All the milk from tuberculous cattle to be boiled before use Control of all imported foreign dairy produce so as to enforce the same standard of purity as in the case of home produce 9 To avoid a sudden national depression in the dairy industry, which would be favourable to foreign produce I further suggest that *the enforcement of these measures should not be simultaneously carried out all through the country*, but that they should be at first enforced in a certain number of administrative areas, to which year after year other districts should be added, until the whole country was under administrative control It is probable that the work could be accomplished in some five or six years

N B —*This paper does not deal with evidence showing that* bovine tuberculosis is communicable to man; this has been done by the author in a series of papers published since 1892 —vide *Medical Chronicle* (1895), THE LANCET (1897), &c

THE TREATMENT OF MELANCHOLIA.

BY LEWIS C. BRUCE, M.D., F.R.C.P. EDIN.,
PHYSICIAN SUPERINTENDENT TO THE PERTH DISTRICT ASYLUM, MURTHLY, N.B.;
AND
H. DE MAINE ALEXANDER, M.D. EDIN.,
ASSISTANT PHYSICIAN TO THE PERTH DISTRICT ASYLUM.

IN the *Journal of Mental Science* for October, 1900, we recorded the results of some observations on the various physical changes occurring during the acute and sub-acute stages of melancholia. In our previous paper we pointed out our belief that the majority of recent cases of melancholia pass through a definite course prior to recovering or becoming chronic; and we divided that course into an acute stage and a sub-acute stage, summing up the symptoms characterising the two stages as follows. A. *Acute stage.*—1. Mental symptoms: great depression, restlessness, vivid hallucinations, and sleeplessness. 2. Pulse rapid, from 90 to 120 per minute, of high tension, and tending to be irregular; arterial pressure high (from 140 to 180 millimetres of mercury). 3 Temperature tending to be febrile (from 99° to 100° F.). 4. Urine scanty; excretion of urea deficient; trace of albumin present. 5. Tongue furred and foul; no desire for food or drink; digestive power of stomach upon coagulated albumin practically *nil;* motor power of stomach weak; bowels constipated and stools very offensive. 6. Skin dry. B. *Sub-acute stage.*—1. Mental symptoms less acute; the patient generally sleeps well; hallucinations, if present, do not affect conduct. 2 Pulse regular, softer, from 70 to 80 per minute; arterial pressure from 120 to 130 millimetres of mercury. 3. Temperature never above 98·4°. 4. Urine more abundant, excretion of urea considerably increased; albumin never detected. 5. Tongue clean; appetite for food and drink returning; digestive power of stomach-juice at first weak but later active; tendency to constipation less marked 6. Skin becoming moist; sometimes perspiration profuse.

Before passing on to the subject of treatment we desire to record certain further observations made upon the urine excreted during attacks of melancholia.

FIG. 1.

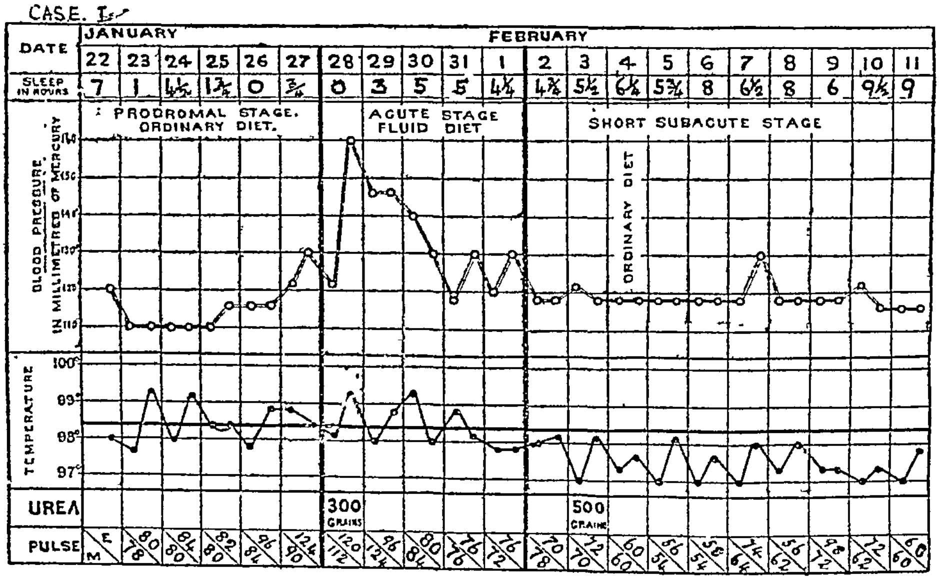

Chart illustrating Case 1.

FIG. 2.

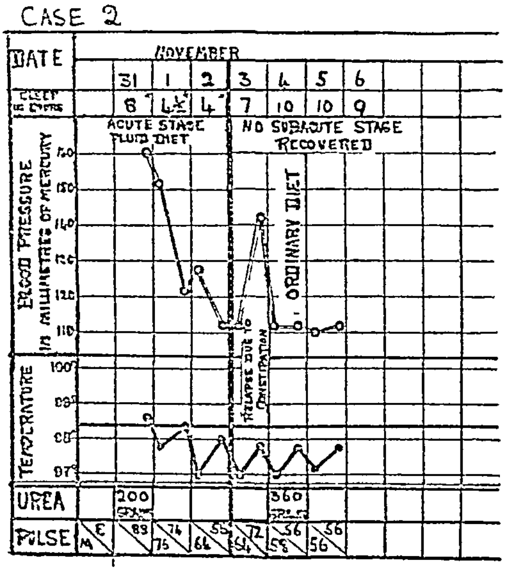

Chart illustrating Case 2.

During the acute stage of the disease we found that the excretion of chlorides was normal, but when this acute stage was unduly protracted they were diminished. The ethereal sulphates were increased during this stage of the disease—an indication of intestinal putrefaction. In the sub-acute stage the chlorides were diminished but rose gradually to normal as the patient recovered. The diminished excretion of chlorides in the urine during melancholia is mentioned by Simon,[1] but without reference to any particular stage of the disease. The ethereal sulphates were not increased, showing that the antiseptic functions of the intestinal secretions had been resumed.

In the course of another year's work we have verified all these observations, and we believe that recent acute melancholia is a disease very amenable to treatment. Our first attempts at treatment were directed towards lowering the blood-pressure by means of erythrol tetranitrate, increasing the excretion of urea by the administration of ammonium carbonate (in 10-grain doses), in obtaining a healthy action of the skin by means of hot-air baths, and assisting digestion and assimilation by artificially digested food. We have discarded erythrol tetranitrate after an extended trial, as, although successful in some cases, it was very uncertain in action. The excretion of urea was certainly increased by the exhibition of ammonium carbonate, but we did not notice any benefit accrue to the patient as a result of its administration, and as this drug only differs from urea in having two more molecules of water it is highly probable that the increased amount of urea obtained in the urine was really due to the oxidation of this alkaline salt in the body Hot-air baths gave little relief and were rather troublesome as a routine practice Artificially digested food soon became intolerably nauseous to patients who already had no desire for food These early attempts at treatment were therefore not encouraging, and more particularly so as they failed to induce a sufficiently increased flow of urine to carry off the accumulating waste products of tissue metabolism

---

[1] Clinical Diagnosis, third edition, p. 297.

In our previous paper we recorded the fact that if a patient, while passing through the acute and sub-acute stages of the disease, be placed upon a fixed measured dietary of solids and liquids the amount of fluid excreted by the patient in the acute stage is less by many ounces than [illegible] comes of [illegible] disease[2] [illegible] because the skin is abnormally dry they are not exhaled in the breath, and as we have shown they are not excreted by the kidneys, as the urine is scanty in amount. There is but one explanation and that is, that in the acute stage of the disease the fluids of the body are in some unexplainable way broken up, an insufficient amount of fluid is left for carrying away the products of tissue waste, and these accumulate in the body There is a deficiency of fluid in the tissues and the demand for it must be met by administrating to the patient a copious supply of liquid, and it is essential that part of this fluid should be nutritive and easily assimilated

In the treatment of our last eight cases of acute melancholia we have discarded all our earlier attempts at treatment and have worked upon the lines above indicated The patients upon admission were put to bed and placed upon an exclusively fluid diet of three pints of milk and three pints of weak tea (sweetened with sugar) per diem and as much water as the patient cared to drink The tea must be weak, as if strong it tends to raise the mean blood pressure[3] Persons suffering from acute melancholia are as a rule thirsty and take this fluid diet readily No solid food was given until the patient asked for it and complained of hunger The result of this treatment in these eight acute cases of the disease has been most satisfactory In every case the

FIG 3

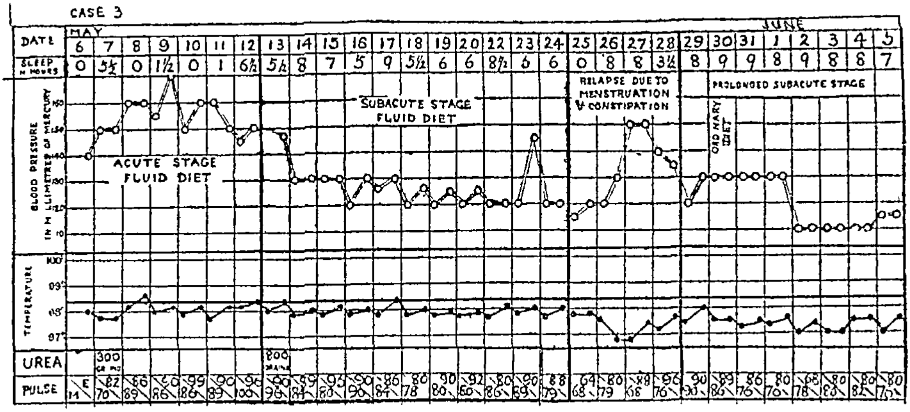

Chart illustrating Case 3

FIG 4

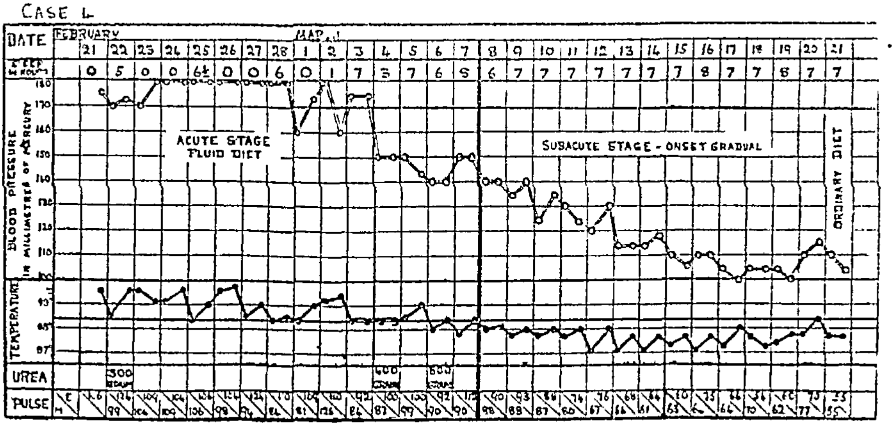

Chart illustrating Case 4

---

[3] Oliver Blood and Blood pressure p 195.

urine increased in amount, the skin acted freely, and the excretion of urea was augmented—in some of the cases to 800 grains per diem. The arterial tension fell rapidly and steadily to normal or subnormal and the habit of sleep returned. The only drug administered was citrate of potassium in from 20 to 40-grain doses thrice daily. This was gradually reduced and finally stopped altogether when the nitrogenous equilibrium was re-established.

Early treatment is imperative in this disease, and our experience has shown that those patients who had been ill for some considerable period before admission took longer to recover than those in whom the disease was of comparatively recent onset. Of our eight cases five were treated early and in none of these patients did the acute symptoms last more than a week, and in them the sub-acute stage was either absent or of only a few weeks' duration. The remaining three cases were of long standing, and in them the acute stage lasted from two to three weeks and the sub-acute stage was prolonged for many weeks.

Relapses.—We have had no serious relapse during the treatment of these eight cases, and any threatening of such was due to one or more of the following causes. 1. The obstinate constipation so frequently associated with melancholia if not regularly relieved is a certain cause of relapse. In treating this symptom in our cases we used salines in combination with strychnine and when necessary enemata. 2. Menstruation temporarily accentuated all the symptoms, mental and physical, of the disease. 3. Gastric irritation induced by putting the patient too early or too suddenly upon a solid dietary.

Summary.—We believe melancholia to be a disease of disordered metabolism and that treatment should be directed towards increasing the excretion of waste products of this metabolism through the channels of the urinary and integumentary systems, and we mechanically accomplish this end by administering to our patients an abundant fluid dietary. By means of this treatment the blood gets rid of its overcharge of waste products and the arterial tension falls. We assist digestion by giving milk frequently, and in small quantities, as it is the most easily assimilated food. We consider the forcing of solid food (or such food as custards) upon a patient suffering from acute melancholia just as injudicious treatment as would be the feeding of a patient suffering from typhoid fever exclusively on beef-steaks. We append four charts illustrative of our cases, with a short summary of each case. Each chart shows the temperature, pulse, arterial tension, and the amount of sleep obtained from day to day. The amount of urea excreted on certain days during the 24 hours is also shown diagrammatically. A small additional table illustrates the fact that while the patients were on the fluid diet their loss of weight was practically immaterial.

Weight Table.

Cases.	Length of time on fluid diet.	Weight lost.	Weight gained.
1	7 days.	0	0
2	5 „	0	0
3	23 „	2 pounds.	—
4	28 „	3 „	—
5	8 „	0	0
6	38 „	1 pound.	—
7	33 „	5 pounds.	—
8	11 „	—	5 pounds.

CASE 1.—The patient was a female, aged 34 years. The chart is interesting because it shows the attack from the commencement. The temperature became febrile on Jan. 23rd, but the tension did not rise until the 28th, when the symptoms became very acute. Under fluid diet treatment and rest in bed all the symptoms had subsided by Feb. 1st. On the nights of Jan. 29th, 30th, and 31st sleep was obtained by the administration of two drachms of paraldehyde. She made a good recovery. Weight is rapidly lost during the onset of the disease and this patient lost nine pounds in seven days though she was on ordinary diet.

CASE 2.—The patient was a female, aged 64 years. The attack was treated early—within a week of onset. The acute symptoms lasted only three days. Sleep was obtained by the administration of two drachms of paraldehyde on the nights of Oct. 31st and Nov. 1st and 2nd. There was practically no sub-acute stage. The patient recovered.

CASE 3.—The patient was a female, aged 42 years. She had been ill for one month prior to admission to hospital. The acute stage lasted for seven days. Sleep was obtained upon the nights of May 7th and 9th by the administration of two drachms of paraldehyde. The sub-acute stage was complicated by a threatened relapse and was prolonged, but the patient has now completely recovered.

CASE 4.—The patient was a man, aged 34 years. He had been ill for two months prior to admission. The acute stage lasted for 15 days. The onset of the sub-acute stage was gradual and the patient, though much improved, is not yet recovered at the present date (June 20th, 1901). In the acute stage sleep was obtained upon the nights of Feb. 22nd, 25th, and 28th by the administration of two drachms of paraldehyde.

Murthly, N.B.

THREE CASES OF PRURITUS ASSOCIATED WITH LYMPHADENOMA.

BY WYNDHAM COTTLE, M.D. OXON.,
PHYSICIAN TO THE SKIN DEPARTMENT, ST. GEORGE'S HOSPITAL, AND CONSULTING SURGEON TO THE HOSPITAL FOR DISEASES OF THE SKIN, BLACKFRIARS;

AND

LEE DICKINSON, M.D. CANTAB.,
ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL.

CASE 1.—A woman, aged 42 years, was admitted into St. George's Hospital on Feb. 20th, 1901, under the care of Dr. F. G. Penrose who kindly permits this publication of the case. The patient was suffering from well-marked lymphadenoma. Her illness dated from the autumn of 1899, when she lost strength and noticed lumps in the neck. She took to bed in November, 1900. On admission she was depressed mentally and physically and was markedly anæmic. The legs were œdematous; in the neck, the axillæ, and the groins were masses of enlarged glands, and over the anterior mediastinum was found extensive dulness, probably due to a glandular tumour. The patient sweated much and the temperature inclined to be hectic. The blood was examined on several occasions and showed only simple anæmia with moderate leucocytosis. The red corpuscles were generally about 3,000,000 per cubic millimetre; the white varied from 8000 to 14,000—the lymphocytes being in the fairly normal proportion of 18 per cent. Intense irritation of the skin was complained of at times, affecting the whole body, but more especially the neck, the shoulders, the back, and the outer sides of the limbs; and when the patient was uncovered she made violent efforts to scratch. Scratch marks were conspicuous all over the body, and there was brownish discolouration of the skin, especially below the eyes, at the bends of the elbows, in the axillæ, and on the inner sides of the thighs. On March 13th Dr. Cottle was consulted about an eruption of pemphigus which had appeared on the legs, accompanied by increased irritation of the skin. The eruption improved rapidly under an ointment of tar and in a month practically disappeared, though itching continued. The general condition, however, steadily deteriorated, and on May 3rd the patient was removed by her friends to a Home for the Dying. It should be mentioned that before the pemphigus appeared arsenic had been given in the form both of Fowler's solution and of cacodylate of soda. Whether or no the arsenic had any causal relationship to the pemphigus, it was certainly not responsible for the pruritus and pigmentation, both of which were of older standing.

CASE 2.—A female patient, aged about 20 years, was sent to Dr. Cottle by Dr. G. M. Pittock of Margate on Nov. 11th, 1896. The history given was that in June, 1896, being already somewhat ailing with enlarged glands and anæmia, she underwent some worry in her work and was vaccinated upon her appointment to a clerkship in the Post Office. Soon afterwards she came out in an eruption of papules which was suspected of being secondary syphilis from the vaccination. When seen by Dr. Cottle she was thin and very anæmic, with masses of enlarged glands at the root of the neck She complained of intense itching of the skin, especially at night. The skin was much pigmented generally —least on the legs and most on the abdomen, around the eyes, and on the flexures of the elbows—the colour varying from a deep yellow brown to that of light nutgall There were numerous deep scooped-out nail grooves or furrows in the skin, especially at the back of the neck, with some papules on the face and many small white scars on the neck and chest, probably where the skin had been scooped out by the nails Dr Cottle regarded the affection of the skin as due to malnutrition and in no way connected with vaccination or syphilis Sir William Gowers, to whom also the patient was sent, remarked in a letter to Dr Cottle that "she now presents symptoms of subacute lymphadenosis with (possibly pseudo-) Addison's disease" Remarking the enlargement of glands and the profound pigmentation of the abdomen, he observed "The pigmentation may be due to enclosure of the sympathetic plexuses of the abdomen in masses of enlarged glands, though these cannot be felt See article on Hodgkin's disease in Reynolds's System of Medicine, vol. v, p 376" Large doses of iron and arsenic were prescribed, together with rest, good feeding, cod liver oil, tar lotion, and carbolic acid ointment The pruritus was relieved, but the patient died on Feb 2nd, 1897, death being attributed in the medical certificate to lymphadenoma in the first place and to Addison's disease secondarily

CASE 3—This is the case of a male patient, aged 34 years, who had spent some years in India In December, 1896, he met with a dogcart accident in that country, sustaining some cuts and abrasions, as a consequence of which the right leg became inflamed. A month later he was attacked with "septic rheumatism" in a very severe form, affecting almost every joint of the limbs and also the neck, the jaw, and the eyes After a long illness he was sent home to England, where he apparently made a good convalescence, so that at the end of 1897 he was allowed by competent authority to return to India. At this time some glands in the groin, the axilla, and the neck were already slightly enlarged Towards the end of 1899 an abscess or carbuncle formed on the left thigh and failed to heal in spite of frequent incisions A voyage to Australia was undertaken but without resulting in benefit Œdema of the genitals and lower extremities set in and the patient was finally invalided to England, where he arrived in May, 1900 The thigh was now operated upon by Mr F C Abbott who removed a quantity of diseased tissue leaving an area of the size of the palm of the hand to heal by granulation In the course of the summer this area became slowly though securely healed—a point worth mentioning as having some bearing upon the nutrition of the skin. The general condition was now one of pronounced lymphadenoma *the disease being apparently limited to the* lymphatic glands and most advanced in the inguinal, pelvic, and abdominal groups, but all the other groups were obviously affected The blood showed nothing characteristic beyond a leucocytosis which might be referred to the suppurating wound Dr Patrick Manson, who kindly saw the patient in consultation with Dr Lee Dickinson *and* Mr R. T P. Collyns of Wimbledon, made a special examination of the blood for malarial and filarial parasites, but with a negative result. Not to record what is immaterial to the present purpose, the patient, after many vicissitudes of febrile temperature, dropsy, dyspnœa and various abdominal troubles due to continual changes in the size of the glandular tumours, sank from exhaustion and inanition on June 1st 1901 Throughout the illness—certainly for the last 18 months—not the least of his troubles was persistent pruritus of the whole skin, especially, perhaps, of the hands, the shoulders, the neck, and the scalp, but any part which might happen to be exposed and within reach was immediately subjected to scratching On the covered parts of the body small papules and furuncles were of frequent occurrence but the intensity of the pruritus varied quite independently of any eruption Eventually the skin of the trunk, and to a less degree that of the face and the arms became pigmented to a tint that raised some suspicion of suprarenal disease but the pigmentation may have been due to a prolonged course of arsenic which was only stopped upon the appearance of a severe eruption of herpes zoster The arsenic, however was not the cause of the pruritus which set in long before the administration of the drug and continued for several months after its discontinuance

Remarks—*Those three cases suggest the existence of a* real connexion between lymphadenoma and pruritus—something more than mere coincidence To say the least of it, pruritus is not a common or widely recognised complication of lymphadenoma which is itself *a rare disease, and Osler* is the only text-book writer we know of who refers to its occurrence. Neither Trousseau nor Gowers, both of whom describe certain eruptions in lymphadenoma, mentions the occurrence of pruritus, but Nékám of Budapest, in a recent monograph upon the skin affections of leukæmia, refers incidentally to those of pseudo leukæmia or lymphadenoma and includes pruriginous affections in the list. The only unequivocal examples of pruritus in lymphadenoma that we have met with in the dermatological literature of the last few years are two cases recorded by Hallopeau and Prieur,[1] and these two cases seem to be essentially of the same kind as those which we have just described We conclude therefore, that lymphadenoma entails a certain degree of liability to pruritus, and our own three cases would seem to show that this complication is an unfavourable sign. It is unnecessary to allude to the constant and tc [illegible] which is thereby added to a [illegible] will only discuss the nature and [illegible] tion As for the prognostic [illegible] can only point to the rapid course of the lymphadenoma in Case 1 and Case 2, and to its inveterate character in Case 3 in spite of many fallacious improvements and every favourable circumstance of fresh air, luxury, and attention. In this connexion it is of interest to refer to a severe but much more chronic case of lymphadenoma which was shown by Dr Lee Dickinson at a meeting of the Clinical Society of London last April. In this case, although the skin has become extensively affected with lymphoid growth, pruritus is, and always has been entirely absent

In the three cases here reported the pruritus clearly did not depend upon gross skin lesions such as growths or eruptions, although papular eruptions of some sort and lesions due to scratching were generally present, but would seem to have been akin to the itching that occurs in jaundice and may with probability be attributed, in part at least, to a poison in the blood or in the lymph. Whether in such cases some special toxin is produced by the lymphadenoma or whether the pruritus results merely from obstruction of the lymphatic circulation by the glandular tumours and consequent vitiation of the lymph is a matter for speculation, but certainly the former theory is not inconsistent with the febrile temperature that characterises severe cases of lymphadenoma It should be *borne in mind that degenerate and* ill nourished skins itch In the pruritus that occurs in the aged and in those of feeble circulation and health the most appreciable changes in the skin are those associated with malnutrition and atrophy—dryness accompanying paleness or pigmentation, warts and moles, dilatation of vessels, and *in other parts a* wasted state of skin tissue so that it feels thinner than natural and has in great measure lost its elasticity, and in these conditions there is no direct evidence of toxic influences The pruritus of jaundice possibly belongs to the same class for it does not set in, as a rule, till after the jaundice has existed for some time or has begun to decline. At the opposite end of the scale we have the pruritus of gout, which is a pure example of the toxic variety, for it may be and generally is, associated with a perfectly healthy condition of the skin.

The cases which form the subject of this paper would seem to belong to an intermediate class in which it is difficult to know how far to attribute the pruritus to malnutrition of the skin and how far to toxic influence We must even be prepared to allow that the neurosis of sensation which constitutes the pruritus is of reflex character and due to local irritation elsewhere than in the skin—for example, in the abdomen from enlargement of the mesenteric glands Be this as it may, we have little doubt as to the prognostic significance of pruritus in lymphadenoma, and that this complication especially if attended by pigmentation of the skin is of grave augury in cases which upon other grounds do not seem utterly hopeless

With regard to pigmentation in lymphadenoma we have already quoted the views of Sir William Gowers in Case 2, and it may be *opportune to remark* that the late Sir George F Paget founded similar views upon a post mortem basis In a former number of THE LANCET[2] is reported a case under the care of Dr Paget (as he then was) which was described as "lymphadenosis with brown pigmentation of the skin" (characteristic of Addison's disease). On post-mortem examination the suprarenal bodies were found perfectly normal, but the semilunar ganglia and solar plexus were involved in a closely aggregated mass of enlarged glands. It must not be forgotten, however, that long-continued scratching will itself lead to pigmentation, and it is a curious fact that in Sir G. E. Paget's case the patient complained much of irritation on the palms of the hands and soles of the feet, and marks of scratching were noticed on several parts of the body.

[2] THE LANCET [illegible] 22nd [illegible]

We have purposely avoided any discussion of the pruriginous or other skin affections of leukæmia as distinguished from lymphadenoma, but for the convenience of those who are interested in the subject we may refer to Nékám's publication already mentioned and to a long article on the subject, with an elaborate bibliography, by Pinkus.[3]

CONGENITAL HEPATIC CIRRHOSIS WITH OBLITERATION OF THE BILE-DUCTS.

By G. PARKER, M.A., M.D. CANTAB.,
ASSISTANT PHYSICIAN TO THE GENERAL HOSPITAL, BRISTOL.
WITH NOTES OF ADDITIONAL CASES BY E. L. WALKER DUNBAR, M.D. ZURICH, AND THEODORE FISHER, M.D., M.R.C.P. LOND.

THE recent papers of Rolleston, Ford, and others, with the older researches of J. Thomson, show the importance of these somewhat rare cases. It is possible that they may throw light on the problems of the production of biliary cirrhosis in the adult or explain some of the obscure forms of cirrhosed liver in older children, whether we finally regard them as due to congenital absence of the bile-ducts or to obstruction by calculi or to a poison in the fœtal blood acting on the liver-cells and on the bile-ducts. The following case illustrates many of the points which have been raised by previous observers.

CASE 1.—A male infant was under my observation from Feb. 27th, 1901, till his death, at the age of six months, on April 27th. He seemed quite well and strong when born and was fed at the breast for two weeks or more. He had no jaundice and passed at first meconium and then yellow stools, but in the third week violent vomiting occurred for several days. He was in consequence weaned, but became jaundiced and the stools changed to a white hue. About Jan. 1st he had been placed under the care of Dr. E. L. Walker Dunbar for six weeks and was then admitted by her into the Women's Hospital for 14 days. Dr. Dunbar writes that at that time he took food well and passed stools quite devoid of bile, and white, except when ox-gall or calomel had been administered. In the hospital he was fed at first with milk-and-water, then with condensed milk, and finally with Nestlé's food. In the first week he gained weight, but having lost again during the second week he was sent home to be under his mother's care, and the unfavourable diagnosis was made known to her. When seen by me at the General Hospital on Feb. 27th he was well nourished but deeply jaundiced and the stools continued quite white. The abdomen was slightly distended, but nothing else abnormal could be detected. Later the jaundice became of a brownish tint, and the liver and spleen were moderately enlarged and distinctly palpable. There were no symptoms of syphilis. He was treated as an out-patient for about seven weeks, receiving liquor hydrargyri, Scott's emulsion, and other preparations, and with the exception of occasional dyspeptic troubles and the slightly increasing jaundice his health remained good. On April 25th he seemed failing; slight ascites occurred, though without enlargement of the abdominal veins; there was some irritation of the skin over the chest, otitis *media* was noted, and the mother reported that a little blood had been passed per rectum. He was taken into the hospital. On admission he appeared to be fairly vigorous and took his meals well, but the urine was deeply tinted and contained numerous granular casts. The stools became yellow again, possibly from admixture with the urine, and he died suddenly on the 27th.

As regards the family history the mother stated that she had always enjoyed good health except for occasional attacks of tonsillitis. Her first pregnancy had miscarried, in the second she had twins, and in the third she had a healthy child, all of whom were still alive. During her last pregnancy she suffered much from what she took to be dyspeptic troubles and was confined to the house for some weeks. Dr. Dunbar tells me that three years ago the mother brought to her a male infant, one of twins, with a syphilitic lesion on the thigh which rapidly yielded to mercurial treatment. The mother becoming again pregnant fell into bad health, but quickly improved under similar measures which were continued till her confinement. As far as is known no fresh treatment was needed before the last confinement.

The necropsy was made 50 hours after death by Dr. J. M. Clarke. It was noted that the body was stained a deep but bright yellow and that all the organs were similarly coloured. There was very little subcutaneous fat, but the heart and lungs were normal in every respect. The liver weighed about 11 ounces, which is nearly double the normal weight for a child of that age. It was of a very deep green olive or bronze colour and smooth in section. The substance of the organ was not friable or granular and, on the other hand, it was not specially hard. In the neighbourhood of the portal fissure there was much thickened connective tissue, and scattered through the liver around branches of the ducts there was an excessive amount of the same tissue, but this condition did not apparently extend through the whole substance. No concretions could be found in the gall-bladder or the ducts. A portion of the common duct was enormously distended and contained a clear fluid with deposits of dark pigment on the walls. The papilla of the common duct in the duodenum was prominent, and both in the portal fissure, in the mesentery, and behind the peritoneum were several enlarged firm glands of a reddish colour. On further examination the gall-bladder was found to be thickened and apparently completely closed. No trace of the common duct could be discovered for half of its length; the distended portion was about an inch in length and of the size of a pigeon's egg. The spleen weighed five ounces and was large and firm with patches of thickening of the capsule. In the kidneys the cortex was swollen, but the capsule stripped easily. Microscopical examination of the liver showed extensive fibrosis mainly surrounding the lobules, but invading them in places and cutting off islets of liver cells. Small bile-ducts were numerous. Nowhere was there small-celled infiltration of the margin of the fibrous tissue, which may be taken to indicate that the fibrosis was not progressive. The liver cells showed no degeneration and the contents of the bile-ducts were dark and prominent.

By the kindness of Dr. Dunbar and Dr. Theodore Fisher I am able to give notes of two other cases observed by them and not previously recorded.

CASE 2.—Dr. Dunbar says: "I delivered Mrs. L—— of a living boy in 1877 who was deeply jaundiced at birth. The mother remarked at once upon the colour, adding that she had had another child like it who had died. I afterwards learnt that she had lost previously six children in early infancy, all born alive and all deeply jaundiced. They lived from a few days to a few weeks. J. L—— lived for seven months an uneasy existence, suffering from sickness and constipation. The diet was carefully regulated and every effort was made, more or less unsuccessfully, to procure a food acceptable to his digestive organs. The stools were hard and scanty and always smeared rather than incorporated with yellowish-brown colouring matter. I made a post-mortem examination and found the liver enlarged. The bile-ducts seemed to me to be replaced by mere connective tissue, but the condition of the stools made me think that there must have been some communication, however minute, between the liver and intestine. On examination of the fresh liver tissue I could not satisfy myself that there was any definite cirrhosis or destruction of the cells. Four out of 11 children of this family lived to adult life. One of them showed symptoms possibly due to hereditary syphilis, but in the others none were observed."

CASE 3.—Dr. Fisher writes: "A male child, A. B——, was first seen by me nine weeks after birth. It was then deeply jaundiced, of a dirty yellowish colour, with a tinge of green. The colour was sufficiently deep to be perceptible over the gums and soft palate. The child was thin and weighed only seven pounds, but could not be said to be either drowsy or restless and appeared fairly comfortable. There was a rash on the buttocks very suggestive of syphilis. The liver could be felt one and a half inches below the costal margin and the spleen about three quarters of an inch. The mother stated that the child had been of a deep yellow colour from the time of birth and that the motions were generally white, but sometimes of a pale yellow. There were five other children in the family alive and well, and the mother had had no miscarriages. During the time the child was under observation the bowels were moved three or four times daily. The motions were semi-solid and like white lead in consistence and colour. There was never a trace of yellow in them. The urine was of a reddish yellow and gave a marked reaction with nitric acid. The saliva was tested for the sulpho-cyanide reaction and gave a faint colour. Five weeks later the child died. The liver and spleen were found to be much enlarged. The gall bladder was present but the common duct could not be found. There was nothing noteworthy in any of the other organs. Microscopic sections of the liver showed well-marked multilobular and monolobular cirrhosis and numerous small bile ducts. Some of the bile ducts were distended with dark material and dark granules were seen in many of the liver cells."

---

[3] Archiv für Dermatologie und Syphilis, October, 1899.

These cases, then, seem to be rare, for Rolleston can only find 59 recorded instances, of which three were operated upon, one of them, Treves's case, being successful. This last case, however, may be of a different kind, for the jaundice had not commenced till the third year instead of within a day or two of birth, and the patient was not operated upon till his nineteenth year. It has been stated that none of the typical cases survive more than eight months, mild ones may survive and be mistaken later for alcoholic cirrhosis in children. They must be carefully distinguished from simple icterus neonatorum and septic jaundice, though umbilical and other hæmorrhages seem not uncommon in them. In this patient no organisms except the bacillus coli were found in the dilated portion of the duct, and the general health remained good in spite of the extreme jaundice. Nor do they resemble the *ictère splénomégalique* of French writers, which seems to occur in older children, and presents a gigantic spleen extending over a large part of the abdomen, and ascites, stunted growth, clubbed fingers, deep jaundice, and enlarged abdominal veins.

Perhaps the most common cause of large liver in childhood is syphilis. Syphilis cannot be traced in many of these patients with obliterated ducts though Thomson thinks that it may intensify the morbid process at times. Moreover, the condition of the liver is quite unlike that which is due to the luetic infection. Finally, the anæmia with a large spleen and liver found in some rachitic and other children may produce slight jaundice, but it shows no other points of resemblance and is frequently cured.

The first question to be solved is whether the changes in the liver are prior to those in the ducts or *vice versâ*. Where no meconium has been passed the disease must have arisen at a very early stage of fœtal life but in this patient and several others neither white stools nor jaundice appeared for some time after birth. If yellow stools are passed for some days it seems strong evidence that the bile channels are open after birth and therefore that no congenital failure of development has existed. We can hardly weigh against this fact the cases referred to by Dr. Rolleston and Dr. Dunbar where the changes in the liver were slight and recent and those in the ducts well developed. If, however, we think that both changes may occur after birth in some patients from inflammatory processes, these cases are not without importance. Thomson, indeed, finds that instances have occurred where the jaundice was very deep and that yet the ducts were pervious. He adds *that if death takes place early no lesion* or only some thickening of the duct walls may be found, while it is in those who live some months that extreme degeneration and even complete absorption of the ducts are generally found. This would seem conclusive, but Thompson suggests that as the bile found is usually much thickened virtual obstruction of the ducts may have been the cause of the cirrhosis of the liver. However it appears proved that the complete destruction of the ducts is a secondary process and the only likely explanation offered is that of Rolleston that owing to their extreme narrowness at birth they are easily destroyed by catarrhal and other inflammation, just as stenosis of the larynx is found more commonly in children from a similar cause. In adults the causes of cholangitis are the presence of calculi and perhaps of typhoid bacilli. Indeed the formation of calculi is referred by some writers to the presence of an infective agent leading to chronic catarrhal changes. Calculi are exceedingly rare in infants, only about eight have been placed on record. It would seem, therefore, that we must reject as causes either developmental failure or calculous obstruction, and recognise an inflammatory process occurring either in fœtal life or afterwards affecting the liver, the ducts, and the bile itself in varying degrees, and bearing in mind the presence of multilobular changes in some patients at least, there is evidence in favour rather of a descending infection than of one ascending the bile ducts. The obliteration of the ducts is a later symptom due in part to mechanical factors.

We may now turn to another line of argument. The cirrhosis is largely of the monolobular or biliary type, though more or less mixed with the multilobular. What, then, is the cause of biliary cirrhosis? The best known class of cases is that known under the name of Hanot, which is usually regarded as infective in origin. Of late much evidence has been brought forward to show that some form of cirrhosis may be due to obstruction of the ducts. Cheadle indeed, says that in the majority of cases of obstructive jaundice no cirrhosis follows,[1] but Vaughan Harley and others have shown by experiments on animals that in them biliary cirrhosis can be produced by ligature identical anatomically with that seen in Hanot's form. Mangelsdorff in 1882 collected 184 cases in man of cirrhosis with duct obstruction and even argued that any form of cirrhosis might accompany this condition. Ford, reviewing the whole subject in the present year,[2] found 24 additional cases and includes several of these congenital ones though he omits alcoholic and syphilitic cases and those due to well known poisons. He regards it as now certain that in animals a damming back of the bile leads of itself to cirrhosis, while in man cirrhosis also follows on obstruction, but this is due in part to the inflammatory conditions which are always present. The cirrhosis, moreover, cannot be anatomically differentiated from that seen in Hanot's type but the general symptoms accompanying it are totally different.

Now in this patient and others the general clinical picture is much more like that of Hanot's type than that which Ford finds in cirrhosis due to obstruction. Ford, indeed, rather strangely reckons these congenital cases among his instances of obstructive cirrhosis in spite of his own teaching, perhaps from grouping them with the few instances of calculi recorded. Thus, in obstruction he points out that the course of the disease is acute, with rapid loss of flesh and symptoms of portal obstruction. Yet in this patient and others like him the course of the disease was chronic, without much emaciation or loss of appetite. There were no enlarged abdominal veins, or œdema, or, until the final stage when nephritis had set in, any ascites. Indeed, but for the kidney poisoning there seemed no reason why he should not have lived a considerable time in fair health. Thomson remarks that the interference with the general nutrition is usually much less than might be expected and that ascites is only occasional in congenital disease. Of course, as obliteration of the ducts is added to the cirrhosis at a later stage we get absolute exclusion of the bile from the bowel without any intermission of symptoms and finally a fatal termination, while in the adults suffering from Hanot's disease there are intermissions. On the whole then we have in some of these cases at least a complete picture of hypertrophic biliary cirrhosis only different from that seen in adults by the results of a secondary obliteration of the bile-ducts. What the poison or infection is which leads to it is by no means certain. The gastro-intestinal disturbances in the parent during pregnancy occasionally noted may point to the source of the mischief as Rolleston suggests, but until we know the cause of the much debated biliary forms of cirrhosis no conclusion is possible.

Clifton, Bristol.

INUNCTION v. INTRA-MUSCULAR INJECTION IN THE TREATMENT OF SYPHILIS.

By C. F. MARSHALL, M.D., B.Sc. Vict., F.R.C.S. Eng.,
ASSISTANT SURGEON TO THE HOSPITAL FOR DISEASES OF THE SKIN, BLACKFRIARS.

A comparison of the different methods of treating syphilis is difficult owing to the length of time during which it is necessary for patients to be under observation. The present contribution, although necessarily imperfect, may be of some value as it deals with 69 cases which were under my continuous observation while I was resident medical officer at the London Lock Hospital, most of them for more than a year. Of the patients in these 69 cases 37 were treated by intra-muscular injection and 32 by inunction during the active symptoms of secondary syphilis. When the active symptoms had cleared up the patients were put on a course of pills—as a rule, two grains of blue pill twice daily. The method of intra-muscular injection employed was that introduced by Mr. J. A. Bloxam some time ago and still employed by him. Ten minims of a solution of sal alembroth, containing one-third of a grain of the salt, are injected by means of a platinum-iridium needle deeply into the muscles of the buttocks. The injections are performed once a week into alternate buttocks. The inunction was done with unguentum cinereum, consisting of one part of mercury, one part of lanolin, and half a part of olive oil. About half a drachm of this is rubbed daily into different parts of the body. The rubbing lasts 20 minutes. A warm bath is taken before each inunction.

---

[1] Lumleian Lectures, 1900.

[2] American Journal of the Medical Sciences, January, 1901.

As to the results of the treatment, by referring to the table it will be seen that there were 16 relapses of the disease during or after treatment by intra-muscular injection, including no less than four cases of severe iritis and one case of early tertiary syphilis. On the other hand, out of the 32 cases treated by inunction there were only seven relapses (two of which were doubtful) and only one case of iritis. Considering that nearly all of these cases were under observation in hospital for a year or more I think that it is justifiable to draw the conclusion that relapses are twice as frequent with the injection treatment as with the inunction method. This view is supported by observations on several hundreds of cases which were observed for shorter periods.

The advantages claimed for injection are secrecy, cleanliness, uniformity of dose, and that it is performed by the surgeon himself; the disadvantages of inunction are its irksomeness and dirtiness. I think, however, that inunction is the more reliable method of the two and that it is the best where rapid mercurialisation is required, as in cases of iritis. The great objection to the intra-muscular injection of perchloride of mercury is the pain caused by it, which is often considerable. Injections of sozoiodol of mercury or of Lang's gray oil are said to be less painful. I have had no experience of these. In treating relapsing syphilis the biniodide of mercury seems the most useful drug.

TABLE OF CASES OF SYPHILIS TREATED BY INJECTION AND INUNCTION RESPECTIVELY.

Case.	Time under observation.	Treatment.	Relapses.	Remarks.
		Injection.		
1	November, 1896, to January, 1898.	5 injections, 3 months pills.	Iritis in eighth month during treatment.	Cured by inunction and biniodide.
2	November, 1896, to November, 1897.	6 injections, 3 months pills.	Iritis in sixth month after temporary omission of mercury.	—
3	October, 1896, to September, 1898.	9 injections, 4 months pills.	Tertiary ulceration in eighteenth month.	—
4	December, 1896, to December, 1897.	4 injections, 3 months pills.	Severe iritis in seventh month, one month after temporary omission of mercury.	Cured by inunction and biniodide.
5	January, 1897, to November, 1897.	6 injections, 1 month pills.	Glossitis and ulcerated throat.	Cured by Donovan's solution and pills of mercury with iron.
6	April, 1897, to July, 1898.	5 injections, biniodide	Nodes on tibia.	—
7	July, 1897, to July, 1898.	6 injections, pills.	Relapsing condylomata.	—
8	May, 1897, to October, 1898.	Several injections and pills.	Circinate syphilide.	Cured by salicylate of mercury pills.
9	September, 1897, to October, 1898.	Several injections.	Circinate syphilide.	Cured by salicylate of mercury pills.
10	January, 1897, to February, 1898.	4 injections and pills.	Erosion of tongue.	—
11	April, 1897, to July, 1897.	4 injections.	Recurrent squamous syphilide and leucoplakia of tongue.	Cured by biniodide.
12	December, 1896, to April, 1897.	6 injections.	Iritis and synovitis.	Cured by inunction and Donovan's solution.
13	April, 1897, to January, 1898.	6 injections and biniodide.	Recurrent condylomata.	—
14	June to August, 1897.	6 injections.	Lesions did not clear up.	Cured by biniodide.
15	June to September, 1897.	8 injections.	Circinate syphilide.	„
16	June, 1897, to October, 1898.	6 injections, pills, and biniodide.	Relapsing circinate syphilide.	Cured by salicylate of mercury pills.
17–37	A year or more.	From 3 to 14 injections (average 6) followed by pills.	*Nil.*	—
		Inunction.		
1	February, 1897, to July, 1898.	10 weeks inunction and pills.	Iritis in fifth month.	Cured by inunction and biniodide.
2	June, 1897, to September, 1898.	4 weeks inunction and pills.	Synovitis of knees.	—
3	September, 1896, to November, 1897.	4 months inunction, 2 months pills.	Erosion of tongue.	—
4	September, 1896, to January, 1898.	5 months inunction, 3 months pills.	Laryngitis.	Cured by biniodide.

AN EPIDEMIC OF CATARRHAL JAUNDICE PROBABLY DUE TO THE ENTERIC FEVER BACILLUS.

BY J. W. DALGLIESH, M.D. DURH., M.R.C.S. ENG.,
L.R.C.P. LOND.

DURING this last summer and autumn there has been a great epidemic of jaundice in Bloemfontein. I myself have treated over 100 cases. The occurrence of several hundred cases of this disease in a small town in several months is a curious and serious thing and one well worthy of our thought and investigation as to its etiology. At the same time there has raged an epidemic of enteric fever, but not worse than what occurs every summer and autumn after the rains. There has been, in addition, a very great amount of serious acute dysentery. This is quite a new feature in the medical *history of Bloemfontein.* It followed the British occupation and was undoubtedly brought by the troops. These three diseases, then—enteric fever, dysentery, and jaundice—have raged here for months. They have risen and fallen together. The outbreak of enteric fever was later than usual in starting last summer because the rains were late, and enteric fever always follows the rains. As it and dysentery increased so did jaundice. Towards the end of October cases began to occur, but there were not many until the end of the year, when the epidemic of these three diseases commenced in earnest. Increasing *steadily every month it reached its height during* April and May, when the number of cases of these three diseases was enormous. Then, during June, the epidemic rapidly subsided. The weather had then for some time been very dry and very cold and bracing.

This epidemic of jaundice is quite a new feature in Bloemfontein. Before the war, during my six years' residence in this town, I did not see any more jaundice than I saw during my six years' practice in Newcastle-on-Tyne Jaundice has now attacked all sorts and conditions of people. It has occurred in the drunkard, in the moderate drinker, and in the abstainer, in those who were careful and in those who were careless as regards their food; in those who had good houses and good food and in those who were badly housed and badly fed; in those who were able to obtain plenty of fresh foodstuffs, fresh milk, vegetables, and fruit, and in those who were obliged to live on tinned foods; in those who had permits to leave the town and who indulged in horse and other exercises every day on the veldt and in those who were closely confined to town and could obtain neither fresh air nor exercise; in those who were overworked and worried and in those who were not troubled in that way; in those who had good teeth, clean mouths, and good digestion, and in those who had the reverse; in those who were constipated and in those who were not; in the new comer and in the old resident; in the rich and in the poor, in the clean and in the unclean, in the well fed and in the starved. The only thing common to all was the insanitary state of the town and the presence of a vast amount of enteric fever and dysentery. Living in a small town closely surrounded by large hospitals, camps, remount depôts, refugee camps, and immense droves of cattle and sheep and horses, with the soil contaminated with many years of filth and disease, with the air full of clouds of dust, with no water that was safe to drink until it was boiled, with fresh fruit and vegetables and other things at times unobtainable unless one had one's own garden, and with all the depressing conditions associated with a long war, it is not to be wondered at that there was much sickness. Every summer and autumn there is an epidemic of enteric fever; last summer this was reinforced by dysentery and this year by jaundice.

I have already said that this epidemic wave of jaundice rose to its height and fell with that of enteric fever and that of dysentery, but it was also mingled with them in other ways As examples I may say that a father had jaundice *while his son and his daughter had* enteric fever; a husband had enteric fever while his wife had jaundice; one brother had enteric fever while another brother had jaundice and a sister had dysentery; and a mother had jaundice while her child had enteric fever. In a large boarding-house during three months seven cases of jaundice, five cases of enteric fever, and three cases of dysentery occurred. I could find numerous other instances, but the above will suffice. The jaundice occurred most in those classes who suffer most from enteric fever. The young unmarried men from home, coming out to appointments and living in hotels and boarding houses, were the greatest sufferers from enteric fever and afterwards, I may add, from dysentery. They also supplied the greatest number of cases of jaundice. The married men suffered infinitely less from enteric fever from the greater care they experienced in cooking and in food and water, and they also suffered very much less from jaundice. Females have never suffered much from enteric fever owing to their drinking tea, which means boiled water, and they only supplied a few cases of jaundice. Children here do not often have enteric fever and then usually in a mild form—I have not yet seen a child with jaundice. In addition, I wish to add that two men who were convalescent from severe enteric fever developed jaundice, and that I have seen three cases of cholecystitis which is certainly a rare disease.

There has been nothing specially to note about the jaundice. It has crept on gradually, as enteric fever often does I say "often" advisedly, for enteric fever very frequently comes on acutely in this country. The jaundice commences with dull headache, languor, depression of heart and nervous system, epigastric pain, tenderness over the gall-bladder, nausea, vomiting, furred tongue, and complete absence of fever. Patients who were at once sent to bed, and kept there, blistered, starved, and purged, recovered most quickly; and those who struggled about soon found out that they must submit to the same *régime.* Another fact is that gastritis, without obvious cause, has been for some time *very frequent here Sometimes it passed off, leaving the* patient very weak; sometimes it has gone on to jaundice; and sometimes ultimately the patient has developed typical enteric fever.

Now, what has been the cause of all this jaundice? It will be readily seen by those who read this communication that I think that it is due to the germ of enteric fever or its toxin, but in what manner I do not know. Is it a mild enteric affection causing gastritis and cholangitis? I think it is; that is the impression I have received in the midst of a large and busy practice. I think that it is a subject well worthy of attention and elucidation by anyone who has the skill and the time to do it, and I write these lines in the hope that someone may be found to do it and also in the hope that some others practising in this colony may be led to give their experience, for I believe that the jaundice has not been confined to Bloemfontein. I think, also, that the Royal Army Medical Corps reports might be interesting. There has been a considerable amount of jaundice amongst the troops.

Bloemfontein.

MEAT ALBUMIN DIETARY IN THE TREATMENT OF TUBERCULOSIS.[1]

BY F. W. FORBES ROSS, M.D. EDIN.,
D.P.H. R.C.P.S. LOND.,
LATE CLINICAL ASSISTANT AT THE NORTH LONDON HOSPITAL FOR CONSUMPTION.

SUCCESS in the treatment of tuberculous conditions, whatever may be the method for the time being which is most generally approved by competent authorities, must necessarily depend in great part on the problem of diet in this disease. Particularly is this so with cases of pulmonary tuberculosis in which defective alimentation is the most troublesome factor of the disease to be dealt with. Defective alimentation may be understood, for all practical purposes, to be governed, on the one hand by the digestive and assimilative powers of the sufferers, and on the other hand to be dependent on the easy digestibility of the food substances exhibited—that is, calculating the amount and quality of nutriment derived from the particular food by comparison with the *amount of digestive effort expended* and its ultimate nutritive value and power of producing stable nutrition when finally assimilated. The problem presented by the digestive and assimilative powers of consumptive patients is perhaps one of the most complex and difficult which the physician is called upon to face in the daily routine of practical medicine. It is just those very articles of every-day dictary, of tried and proved food-value, which, owing to the peculiar circumstances of a consumptive person, are most difficult and trying for his deranged digestive system to deal with even in only a partially complete manner. The ingestion of ordinary food, such as meat, vegetables, fats, &c., and the effort to extract from them their constituent proteids, carbohydrates, &c., in such a manner as to derive benefit therefrom, are often beyond the strength of the patient's naturally defective powers and more frequently cause a tax upon his or her energies which the small amount of nutriment derived is unable to compensate. Almost any rational line of treatment adopted will prove satisfactory and equal to the demands made upon it, provided that the digestion of the sufferer is good and remains so. When digestive powers begin to give out—which will almost inevitably happen in the vast majority of cases—then the fight to make any progress which may be called favourable begins in grim earnest.

---

[1] A paper read before the British Medical Association, Medicine Section (by consent of the President of the section), on August 2nd, 1901.

The above amply accounts for the successes, failures, and general inequalities of results obtained under any of the well-known methods of treating phthisis. Nothing more exhausting and distressing can be well conceived than a continuous effort to derive nutriment from food, unsuitable in quality and quantity, under circumstances of deranged functions and irritative and morbid conditions of the digestive apparatus. Energy is uselessly expended in a stupendous endeavour to extract an amount of benefit miserably incommensurate with the effort and with a result which would only count as a minimum under more favourable conditions. Comprised in the term "digestive power" is the ability of the nervous mechanism of the pulmonary-gastric chain to resist the mutually reciprocal stimuli which the various processes in the one set of organs excite in the other set and *vice versâ.* Marked additional gastric effort, especially accompanied by diminished digestive power as the result of functional or irritative morbid conditions, made more profoundly disturbing by these very conditions, tends to call into action the pulmonary reflexes—i.e.. cough. This last if in itself sufficiently aggravated reacts on the gastric reflex and leads to the manifestation of vomiting, and thus we here have set up a vicious cycle, ending in inability to retain food. As the ultimate result the general nutrition of the patient rapidly fails, his or her powers of resistance to the disease are gravely diminished, and the disease makes swift and devastating progress towards an unfavourable termination.

As proof of the above contention that the easy excitability is due to loss of power, and that the deranged and irritable reflexes require strengthening, the benefit to be derived from small doses of a nerve stimulant such as strychnine, over and above a sedative such as opium, is well known and appreciated. The assimilative powers can be understood to embrace not only the ability to take up and absorb nutriment, but to fix it in the organism, and having done so to be able to retain and keep it in that condition of potential stability and fixation. The stability of the assimilated matter taken up into the organism depends much on the inherent kind and quality of the food exhibited. A good instance of this is shown by the contrast in the behaviour of milk or casein albumin, and meat albumin or myosin albumin[2] as articles of diet in consumptive cases. Milk or casein albumin, where the gastronomic peculiarities of casein albumin can be borne, is taken up with very moderate rapidity, and benefit is obvious only after comparatively large quantities have been consumed. On the other hand, the beneficial results of the assimilation of milk albumin are rapidly dissipated under unfavourable conditions. Meat albumin, on the contrary, quickly and readily manifests its better qualities in the early observable improvement in the sufferer, and the benefit so obtained is not so easily undone as in the case of casein albumin.

Whatever the benefits manifested in the young by a milk diet, the circumstances do not altogether hold good for the adult, and especially an adult needing the utmost possible assistance from food specially adapted for the needs of adult life, which is the case with a consumptive person. Muscularity is the feature of the adult, therefore the proteid of muscle-food is more nearly adapted to the exigencies of that condition of life than the peculiarly adapted food of the infant in whom muscularity is not the predominant note of development. The above can be easily proved by anyone taking the trouble to weigh tuberculous patients fed on either diet mainly. Whether this is due to the fact that the casein albumin of milk is an excreted or excretory albumin and that the albumin of muscle is a fixed and more highly-elaborated and differentiated albumin, or that the marked deficiency of albuminoid-iron in the casein albumin accounts for the superiority of the iron-carrying muscle albumin, has not yet been satisfactority settled. Any benefits accruing from the ingestion of milk albumin can be easily assisted and their stability enhanced and safeguarded by the admixture and addition thereto of the albumins of meat with their many and various good qualities. Further, the resistant and combative forces of the patient to the ravages of the disease seem to be more markedly increased and fortified under a diet of meat albumin, or mixed meat and milk albumin, than under milk alone.

Personal practical experience of the results of feeding consumptive patients tends strongly to confirm the experience of others. Meat albumin or myosin albumin can be used either in a cooked state or as a raw meat-juice prepared from fresh meat and used immediately after preparation. It can be made either by mincing the meat and expressing it, or by the cold extraction process with saline solution.[3] This last can either be used alone as it is or it can be flavoured with port wine, spices, &c. Commercial raw meat-juice preparations on the market possess no advantage over the home-made raw meat extract, and have the additional disadvantage of containing only a small percentage of actual albumin; they are most expensive, and must necessarily be highly charged with chemical preservatives of more or less harmful nature. All the above methods of administering raw meat-juice, home-made and commercial, run the risk of conveying tubercle bacilli from the meat from which they are made; and the meat juices of foreign origin may also contain the spores of anthrax bacilli if they are made from meat where the cattle are subject to that disease. On the other hand meat albumin can be also utilised in a coagulated or cooked condition,[4] and apparently with just as great benefit, judging from practical results. From elaborate experiments made by myself it can be easily and safely put up in tins and sterilised ready for use at very small expenditure.

Héricourt and Richet's[5] researches and experiments with raw meat on tuberculous dogs induce them to attach some importance to the rawness of the meat, its action supposedly being due to a somato-antitoxin existing normally in muscle plasma or serum; actually the reason may really be that more albuminoid nutriment was forthcoming for less digestive effort Perhaps the contention that muscle serum possesses antitoxic influences has some foundation in fact, as persons of well-marked muscular development are known to be less liable to consumption than others not so well developed muscularly. Consumptive patients of good muscular physique do better than those who are not so fortunate. Finally, in cases of profound tuberculosis such as the tuberculous infection of a large serous cavity as the pleura or peritoneum, the patients, however well developed muscularly, seem to lose their muscular tissue at a rate out of all proportion to that occurring in other diseases. This may be that the muscular tissue is used up in a vain attempt at combating the tuberculous poison. Djvorak[6] and Webber[7] speak well of, and recommend, a meat diet strongly in the treatment of phthisis.

At the present time in my wards in H.M. Guards' Hospital, London, is a well-marked case of tubercle of the right apex in a man who began to go down-hill rapidly and to lose weight and become anæmic, with cough and loss of all appetite, under ordinary diet with much milk. He was put upon the albumin made from two pounds of good steak daily and now after three weeks is so much better that all active subjective and objective symptoms have ceased and he expresses himself as *feeling quite well* His condition is *rapidly approaching the* stage known as ‘ arrest ’ [8]

About [illegible] the right pleural cavity c[illegible]eral pints of fluid contain[illegible] Horsell) After paracentesis he was placed on full diet and the right chest was *painted with iodine but this case became one of dry tuberculous* pleurisy, spoken of so unfavourably by Maguire [9] The patient rapidly ran down and became emaciated, weak, and anæmic He was now put on the albumin from one pound of meat daily was sent into the country, and returned after three months with a gain in weight of two stones, ruddy, feeling well, and with what was more important his right pleura apparently well, but thickened This is undoubtedly another case of "arrest" [10] under meat albumin

A case of malaria with a specific taint and beginning tubercle of the lung though doing extremely badly with a most generous diet and appropriate treatment yet is now, under meat albumin as the patient expresses it "a different man" Another striking case was one published in THE LANCET by Dr Fletcher Little and myself [11] which did wonderfully well with meat albumin and open air treatment combined This particular patient had done badly in South Africa, whither he had been sent for cure, but returned much worse with tuberculous laryngitis, yet in two months he had so far recovered as to form h a case of ‘ arrest

The assimilative powers of a consumptive patient are in direct ratio to the relative efficiency of the vital functions of his organism—e g adequate oxygenation of blood leads to increased power of tissue storage and metabolism with withdrawal of pabulum from the blood stream, this in its turn leads to renewed demand for nutrient matter to replace that withdrawn which is met by increased digestive effort of healthier tone The success of the open air or fresh air treatment of consumption is the fact that digestion being improved and appetite sharpened the patient is able to partake of just those articles of food which tend to provide him with nourishment best suited to his needs in return for the increased power of dealing with them

The above factors produced the survival of the high altitude' treatment, "change of air," and in a less degree owing to lack of adequate food the "long sea voyage on a sailing vessel If it be our duty to the consumptive bread earner [12] to provide him with sanatoria for the open air treatment of phthisis, it also behoves us to endeavour to furnish him with easily assimilated foods within the reach of his pocket No matter what method of treatment be found most successful medicinally the factor of diet will ever remain paramount and essential to that method Myosin albumin returns a maximum of nutrient for a minimum of effort, peptonises rapidly and is promptly absorbed throwing little or no stress and irritating over action on the stomach When combined with fresh milk or stimulant extractives it helps to ensure a highly nutritious food and leaves additional power and spare energy for such valuable adjuvants to the dietary as extract of malt, cod liver oil bone marrow hypophosphites &c

THE CONDITION OF THE BLOOD IN SCARLET FEVER

BY F PERCIVAL MACKIE M R C S ENG ,
L R C P LOND ,
LATE RESIDENT MEDICAL OFFICER AT THE BRISTOL CITY ISOLATION HOSPITAL

As the result of the examination of 25 cases of scarlet fever of different degrees of severity and at different stages the following conclusions have been arrived at

Moderate anæmia was a constant feature In half the cases the red cells numbered between 3,500 000 and 4 000 000 per cubic millimetre The highest count was 4,170 000 per centimetre The percentage of hæmoglobin was in direct *ratio to the number of red cells, so that the individual corpuscular* richness kept very nearly normal All the cases were accompanied by leucocytosis to a pathological degree—that is over 10 000 per cubic millimetre This leucocytosis seems to bear no direct ratio to the temperature but varies rather with the severity of the throat lesion and to a less *extent with that of the rash* In most cases the increase of leucocytes began about 24 hours after the appearance of the rash and reached a maximum after the subsidence of the general symptoms and at times varying in different cases from the third to the tenth day Mild cases show a maximum increase about the fourth day after the appearance of the rash, and therefore generally not less than 24 *hours after the complete disappearance of the* rash In the presence of septic complications the duration and intensity of leucocytosis naturally depends upon the intensity and duration of such complications In anginal cases the leucocytosis may be very high (it was 95 300 per centimetre in one case) and in the one fatal case it diminished as the disease became more severe This seems analogous with the blood condition in pneumonia where a decrease of leucocytes in a severe ca e is looked upon as a bad sign Percentage enumeration of white corpuscles was only carried out in a few instances, but in these the chief increase was in the polymorpho nuclear variety and in several cases increase of eosinophile cells was present (5 per cent or 6 per cent)

The above conclusions though not made on a very large number of cases are very much in accord with those arrived at by other observers Thus Hayem [1] states that about 1,000 000 red corpuscles are lost per cubic millimetre during an attack of scarlet fever The diminution is most marked about 24 hours after the fall of the temperature Kolschethoff [2] finds that there is a gradual diminution of red cells to about 3 000 000 per cubic millimetre regeneration taking place slowly and not being complete till about the sixth week. Felsenthal [3] on the evidence of a few cases found no variation in the red cells Zappert [4] gives 4 150 000 per centimetre as the average number of coloured corpuscles Hayem [5] found that the hæmoglobin diminished in direct ratio to the red cells As regards the question of leucocytosis Cabot states that the increase may be noticed as long as six days before the rash appears and that it attains a maximum two or three days after the eruption of the rash It persists for several days after the temperature has fallen to normal and with this remark Limbeck also agrees. The average leucocytosis is given as between 18 000 and 30 000 per cubic millimetre Cabot sums up the question by saying In general the severest cases are apt to have the highest leucocyte count the figures have no direct relation to the amount of fever glandular enlargement or complications in the ear or kidney In reference to the percentage enumeration of white cells Kanthack found that the chief increase was of the multinuclear forms (that is the polymorpho nuclear) Cabot finds the same and also says that the lymphocytes—presumably also the large mononuclear—are decreased An increase of eosinophile cells is noted to 6 per cent or 8 per cent., and even in one case to 15 per cent (Kanthack) and this has been used as a prognostic sign it being stated that such increase except at the commencement of the disease is a bad sign

These observations as far as they go tend to bring the question of leucocyt is in scarlet fever into line with that found in some other diseases notably in pneumonia, and speaking in general terms it seems that this increase is a favourable sign and perhaps bears some near relation to the questions of natural protection crisis and acquired immunity Conversely a deficiency or absence of leucocytosis in a clinically severe case is of bad import and the same may be said of a sudden or rapid drop in a case of increasing severity Further as far as our experience goes the sign is of value in indicating the presence of septic complication such as deep seated suppuration in the neck or obscure middle-ear disease particularly as neither of these conditions is infallibly revealed by the temperature chart The moderate leucocytosis in simple angina—from 20 000 to 30 000 per centimetre—is increased to from 40 000 to 60 000 per centimetre when suppuration takes place, and this sign may therefore be used to indicate operation, as has been claimed in the case of appendicitis. The condition of the throat has an important bearing on the degree of leucocytosis, but as long as the discharge is free the increase of leucocytes is not excessive. Measles can be readily distinguished from scarlet fever, as it is one of the few febrile diseases where there is no leucocytosis. Contrary to the experience of Cabot I found no leucocytosis until the rash had been out for about 24 hours; the statement of his about there being leucocytosis six days before the eruption is difficult to understand, as in most cases that would be before the child was even exposed to infection.

[4] Zeitschrift für klinische Medicin 1893 p 232

[5] Ibid

That the chief increase should be in the polymorpho-nuclear variety is only what one would expect, but the increase of the eosinophile variety is interesting. Those who believe that the coarsely granular eosinophile cell has to do with the production of antitoxin will find their theory substantiated, though unfortunately it does not hold good in other diseases where antitoxins are produced. It seems rather that the eosinophile cells have some relation to skin conditions, as in many skin diseases they are much increased, and if this is the case the greater number should be found in those cases which present the most intense and lasting rash, but neither on this point nor on the question of leucocytosis in relation to acute nephritis have I been able to collect any evidence.

Addendum, June, 1901.—The finding a deficiency of red blood cells is not surprising, as everyone who has been brought into contact with patients convalescent from scarlet fever notices the frequency of anæmia. It is scarcely necessary to add that this fact establishes as a rational one the custom of administering to all children one of the iron-containing syrups—with the possible exception of those who have had arthritic complications.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

BACTERICIDAL EFFECT OF THE BLOOD OF NATIVES OF INDIA ON BACILLUS TYPHOSUS.

BY F. N. WINDSOR, B.SC. VICT., B.A. CANTAB.,
CAPTAIN, I.M.S.

(From the Pathological Laboratory, Army Medical School, Netley.)

THE opportunity being given by the presence at Netley of four Sikhs (invalided for wounds from West Africa) and one other native of India (an adult Bengali) I have, at Professor Wright's suggestion, investigated the bactericidal power of their blood on bacillus typhosus with a view to a possible bearing of such inquiry upon the problem of the comparative immunity of Indian native troops to typhoid fever. The method employed was that recently described by Professor Wright,[1] the details being as follows. A 24-hour old broth culture of the bacillus typhosus was employed and the number of bacteria contained in it was elicited as described in the paper above referred to. A series of dilutions of the culture were then made and a certain volume (about five cubic millimetres) of each was mixed with an equal quantity of undiluted blood serum (drawn an hour or so previously) in a capillary glass tube. After the serum had remained in contact with the culture for 24 hours at a temperature of 37° C. a comparatively large volume of sterile broth was drawn along with the contents of the tube into the mixing chamber at the upper end. The series of tubes were then incubated for 24 hours at 37° C. When the contents of the chamber remained clear the bactericidal action of the serum was assumed to be complete; when it had become turbid, incomplete. In case of doubt the inoculation of nutrient agar decided the question.

The results are shown below in tabular form and may be compared with those obtained from a similar investigation of the blood of several ordinary Europeans:—

Dilutions of Culture employed and Number of Bacilli in One Cubic Centimetre of each Dilution.

—	1 in 5. 40,000,000 in 1 cubic centimetre.	1 in 10. 20,000,000 in 1 cubic centimetre.	1 in 25. 8,000,000 in 1 cubic centimetre.	1 in 50. 4,000,000 in 1 cubic centimetre.	1 in 100. 2,000,000 in 1 cubic centimetre.	1 in 1000. 200,000 in 1 cubic centimetre.	1 in 10,000. 20,000 in 1 cubic centimetre.

European, J. B. C.	,,	Sterile	Sterile	Sterile	Sterile	Sterile	,,

The agglutinative reaction was also tested in sedimentation tubes and gave a negative result with all the above sera.

From these results it would appear that as regards its action towards bacillus typhosus the blood of these five native Indians did not differ to an appreciable extent from that of an ordinary European. The interesting question as to how this action would be affected by an inoculation with typhoid vaccine cannot at present be determined.

Netley.

A CASE OF CYSTINURIA WITH DIAMINURIA.

BY H. A. SCHÖLBERG, M.B. LOND.,
AND
A. E. GARROD, M.D. OXON., F.R.C.P. LOND.

THE observations recorded below have been made on a case of cystinuria in a boy, aged 12 years, an account of whose case appeared in THE LANCET of Feb. 16th, 1901, p. 470. He had been admitted to the Birmingham Children's Hospital for the removal of a cystin calculus from the bladder. We are greatly indebted to Dr. E. A. Sadler of Ashbourne for his kindness in collecting and forwarding samples of the urine and for giving us leave to publish these obse[illegible]tions on the case. The urine was examined at dif[illegible] periods from Feb. 15th to April 18th, the whole tim[illegible] a total of [illegible]0 days. The method employed for de[illegible] is that known as the Udranszky-B[illegible]es the details for those who may wi[illegible]he total urine passed in 24 hours was [illegible]llowing days, the results being tabu[illegible]

[1] Neubauer und Vogel: Analyse des Harns, p. 265.

It will be seen from this that on three occasions out of 10 examinations diamines were found, in one case putrescin (dibenzoyl derivative) being separated as a pure product This is the second case recorded which has given such a result, the other being described by Garcia[2] who was examining the urine of Baumann's case recorded in the same journal in 1889 The evidence that we had separated dibenzoyl putrescin is as follows (1) benzoylating yielded a crystalline compound having the same melting point as dibenzoyl tetra methylene diamine—175° to 176° C , (2) it was insoluble in water , (3) it was soluble to a certain extent in ether and readily soluble in alcohol , (4) the platinum salt of the compound was prepared and the crystals corresponded with those of the platinum salt of putrescin The yield was insufficient to allow of a further experiment and an ultimate organic analysis could not be done

The results obtained with the samples dated April 16th to April 18th indicated a mixture of the two diamines putrescine and cadaverine The melting points of the two dibenzoyl derivatives of these two compounds are 175° to 176° and 130° C respectively, and a mixture of the two would give a lowered melting point corresponding to the proportions of the two bodies present. The melting point of the crystalline bodies separated was in both cases 159° to 161°, *suggesting that we were dealing with a mixture of* dibenzoyl putrescine and dibenzoyl cadaverine, the greater part of which was the putrescine derivative Ether dissolved the greater portion of the mixture leaving a small crystalline residue An examination of the fæces was not made

In conclusion, we wish to emphasise the intermittent character of the excretion of diamines and the necessity of making a repeated examination of the urinary output before deciding that these bodies are absent We wish to express our thanks to Dr F W Andrewes for allowing us to carry out this work in his laboratory

MALARIAL COMA , PREMATURE DELIVERY ; DEATH

By J BELL M R C S ENG , L R C P LOND ,

ACTING PRINCIPAL CIVIL MEDICAL OFFICER, HONG-KONG

A CHINESE prisoner in about the eighth month of pregnancy was suddenly seized with a fit at Hong Kong gaol on June 1st. When seen she was quite unconscious with contracted pupils, stertorous breathing, insensitive conjunctivæ, and a small, feeble pulse Under the idea that she was suffering from [illegible] mia she was transferred to the Maternity Hospital [illegible] rrival she was much in the same condition , the tempe[illegible] was 100° F and she was quite unconscious She pas[illegible] r urine and fæces in bed but by means of a catheter a [illegible] m of urine was obtained , the specific gravity was 1[illegible] was acid, and it contained a trace of albumin. The [illegible] wing day she was somewhat better and she could be roused by loud shouting The temperature was 101° , *the urine contained one sixth albumin* with blood corpuscles and blood casts The labour ended naturally, the child being dead On the 3rd the temperature was 103°, the urine was normal and the patient was still unconscious A blood slide showed numerous malignant quotidian parasites Ten grains of quinine were given hypodermically twice daily, but without any drop in the temperature or improvement in the mental condition. On the 4th the temperature was 106 8° As the patient was evidently sinking lumbar puncture was performed clear serum coming out of the tube which was left in for 48 hours. This, perhaps, combined with ice packing brought the temperature to normal at midnight. The following day the patient seemed to be much more sensible though the temperature again rose to 104° As the blood still showed malignant parasites in large numbers the quinine was increased to 15 grains twice daily, with iron and quinine every three hours The patient slowly again relapsed into unconsciousness, the temperature varying between 101° and 106° till the 7th, when she died.

Necropsy —At the post mortem examination the heart and lungs were found to be normal save for some old adhesions at the right base The liver was cirrhotic and weighed two and three-quarter pounds The kidneys were normal but were much congested The spleen weighed five ounces The brain was soft and congested but there was no increase in the fluid either at the base or in the ventricles A smear obtained from the spleen teemed with parasites

Remarks —As these comatose forms of malaria invariably show a large increase in the cerebro spinal fluid lumbar puncture was tried in the hope of staving off the effects of pressure until the quinine had time to work The result was disappointing, as also was the effect of quinine which in these comatose forms seems to be useless In five days the patient had 145 grains hypodermically with practically no effect

ST GEORGE'S HOSPITAL

TWO CASES OF INTUSSUSCEPTION TREATED BY OPERATION ; RECOVERY

(Under the care of Mr HERBERT W ALLINGHAM)

THE following two cases are good instances of the successful treatment of intussusception by laparotomy, and the best results are obtained when, as here, no previous inflation or injection has been practised. In one important point, however, these two cases differ from most other cases of laparotomy for intussusception in both the vermiform appendix was removed Inasmuch as shock is the chief cause of death in laparotomy for intussusception this addition to the operation is of doubtful value and the utility of the modification is but little increased by the avoidance of possible appendicitis in the future and by the possible formation of adhesions which may tend to prevent a recurrence of the invagination. For the notes of the cases we are indebted to Mr P L Mummery.

CASE 1.—A well nourished child, aged a year and three months, was suddenly seized with acute abdominal pain at 9 A M on March 11th , this was followed by vomiting and diarrhœa, the stools consisting of blood and mucus. The patient had previously been quite healthy except that he had suffered from worms for some time, a worm having been passed just previously to the onset of symptoms The child was admitted to St George's Hospital at 4 A M on the 12th The abdomen was slightly distended and tender, and a firm roundish mass could be felt extending from the right iliac fossa upwards and then across the abdomen at about the level of the umbilicus towards the left side

The A C E mixture having been administered, an incision was made about four inches long just to the right of the umbilicus and extending about an equal distance above and below it On opening the abdomen an ileo-cæcal intussusception was found nearly a foot in length This was reduced easily by squeezing except for the last portion which was rather adherent. The appendix (about four inches in length) was then removed by turning back a sleeve of peritoneum in the ordinary way The wound was sewn up with fishing gut sutures and the dressings were fixed on by passing broad pieces of strapping completely round the body The child was subsequently allowed to move about in bed as he liked He was rather restless all day but after the administration of two minims of tincture of opium he slept well all night

On March 13th the child was sitting up playing with toys *and seemed* to be quite comfortable Two drachms of castor oil having been given without effect in the morning the child was given half an ounce in the evening which resulted in two good stools during the night The patient made an uninterrupted recovery, the stitches being removed on the sixth day The child was allowed to sit up when he wanted to and in fact, did so most of the day The wound was firmly healed on the 25th and the child left the hospital quite well on the 28th

CASE 2.—A well nourished child was in good health until

---

[2] Zeitschrift für Physiologische Chemie, 1893.

April 22nd, when the mother noticed that the stools were frequent and consisted for the most part of blood and slime. It vomited about the middle of the day; this continued and the child was restless and ill until admission to St. George's Hospital on the following afternoon (the 23rd). On admission the child was collapsed, with a subnormal temperature and rapid pulse; it vomited frequently and passed several stools consisting of nothing but blood and mucus. The abdomen was distended and with some difficulty a sausage-shaped mass could be felt on both sides of the abdomen. Nothing was felt on examining the rectum.

An operation was performed at 8.30 P.M. on April 23rd. Chloroform having been administered an incision about four inches long was made as in the first case. An ileo-cæcal intussusception was found involving the whole of the large intestine down to the sigmoid. The bowel was black in colour and slightly œdematous, but still shiny. It was reduced by delivering the mass and reducing it piece by piece by squeezing the intussuscipiens and drawing on the intussusceptum. The last part was rather adherent but was reduced without injury to the bowel. The appendix was then removed as in the first case and the wound was sewn up and dressed. The child stood the operation well and slept for some time afterwards. It was not weaned but was fed by the breast in the ordinary way, the first feed being given by the mother six hours after the operation.

On April 24th the child was very slightly sick after each feed during the day. The bowels acted three times unassisted, the last motion being natural in appearance. The temperature was 102° F. On the 25th the patient was better. The bowels acted slightly. Half a drachm of castor oil was administered with good effect. The temperature was normal. On the 29th the wound was dressed and superficial stitches were removed. On May 4th the remaining stitches were removed; the wound had healed. On the 11th the patient left the hospital quite well.

Remarks by Mr. Mummery.—In neither of the above cases was inflation attempted and in both cases it was found at the operation that such an attempt would have been quite futile. The large incision used in these cases was of great benefit as it allowed of the operation being quickly performed (neither operation took over 25 minutes), a point of the utmost importance in abdominal operations on young children. The appendix was removed in each case with a view to obtaining adhesions in the neighbourhood of the cæcum which we thought might prevent a recurrence of the trouble, while at the same time it removed an organ with unpleasant possibilities before it. Both children were allowed to move about as they liked after the operation and the second child was even taken out of its cot by its mother and put to the breast every few hours, and if this child had had to be weaned it would probably not have recovered. The child being allowed to sit up and crawl about did not appear to interfere in any way with the recovery of the bowel or the healing of the wound which in both cases was perfect.

KETTERING GENERAL HOSPITAL.

A CASE OF RUPTURE OF THE KIDNEY; EXCISION; RECOVERY.

(Under the care of Dr. Daniel D. Lee.)

The question of the removal of a kidney when a urinary fistula has become established must be decided partly by the risk of the operation itself, but chiefly by the functional activity of the other kidney. This should be estimated in all cases before nephrectomy is performed. In uncomplicated cases of injuries to the kidney the mortality is about 30 per cent. and when complicated cases are also included the death-rate may amount to 47 per cent. These percentages are founded on a series of 306 cases collected by Koster.[1]

A labourer, aged 19 years, was admitted into the Kettering General Hospital on Sept. 6th, 1900, 14 hours after an accident at the Kettering Furnaces, in which he was caught between two barrow loads of ironstone. When seen at the hospital he was in a state of extreme collapse. He was very restless, in great pain and distress, and passed blood copiously by the urethra. The hæmorrhage was ultimately checked, but did not cease altogether until the beginning of the third week. His condition was very grave and continued so for several days. The temperature ranged from 99° to 103° F. and the pulse was 140; there were frequent low delirium and almost incessant vomiting. At the close of the first week the cervical glands were inflamed and swollen and in the space between the last rib and the crest of the ilium an ill-defined swelling with faint fluctuation appeared. This gradually increased and could be traced from the outer border of the erector spinæ behind, almost to the middle line in front. Fluctuation became more marked and the presence of pus was suspected. Yet, notwithstanding that on three occasions a trocar was thrust deeply into the swelling, the result was negative. At the same time Dr. Lee felt convinced that he had to deal with a perinephric abscess. It should, perhaps, be mentioned that after the urine had become quite clear the quantity passed was excessive, amounting to 90 ounces in 24 hours.

On Oct. 7th it was decided to operate. Mr. J. P. Roughton gave the anæsthetic and Dr. J. Allinson and Mr. L. W. Dryland assisted. A vertical incision was made along the outer edge of the left lumbar muscles, extending from nearly the last rib to the crest of the ilium. No special difficulty was encountered in the dissection, the deeper stages of which were carried out rather by tearing with the finger and probe than by cutting, and a membrane containing fluid was reached, through which the kidney could be readily felt. The membrane was torn through freely, as was thought at the time, but only a disappointingly small quantity of foul-smelling urine escaped. Two large drainage-tubes were inserted into the cavity and were packed round with strips of cyanide gauze and the wound was dressed. The patient rallied well from the operation; on the two next days there was a considerable amount of discharge on the dressings, but on the third day they were quite dry. The vomiting meanwhile continued and the temperature and pulse showed no signs of improvement. Suspecting that the opening in the capsule was insufficient or that the tubes had either slipped out or got blocked, Dr. Lee put the patient under the A.C.E. mixture and freely lacerated the membrane with the fingers, when an astonishing quantity of urine and pus escaped. The cavity was again drained and the wound was dressed. The vomiting now entirely ceased and the patient gained flesh and strength rapidly. In fact, he was practically well except for the presence of a urinary fistula. It may be remarked that when the cavity was being flushed out on two occasions some kidney tissue came away in the discharges.

After a month's uninterrupted progress it was put to the patient whether he would be content to have a urinary fistula all his life or to have the injured kidney removed. He readily chose the latter alternative and accordingly on Nov. 18th he was put under the A.C.E. mixture, Dr. Lee's colleagues assisting as before. An incision about four inches in length was made a little below and parallel to the last rib, forming an acute angle with the upper end of the wound made in the previous operation. A triangular flap resulted, which when reflected brought the kidney well within reach. The capsule was reflected from the pedicle as far as possible and the kidney was withdrawn partially through the wound. The ureter was now sought for, but from the extremely matted condition of the pedicle it was found impossible to isolate it. It was decided to include the ureter with the blood-vessels in the same ligature. The pedicle was therefore transfixed with a stout double silk ligature and was treated exactly like an ovarian pedicle and the kidney was removed. The cavity was well plugged with cyanide gauze and the dressings were applied. The patient bore the operation well, but became very collapsed on the next day when the dressings were removed. However, after being transfused by Mr. Roughton and Mr. Dryland with normal saline solution, he rallied and subsequently made an uninterrupted progress to complete recovery. He is now, and has been for three months, back at his old work again, feeling, he says, as well as ever.

Remarks by Dr. Lee.—The only comment which I wish to make on the treatment of the case is with regard to the management of the ureter. The authorities on the subject within my reach say that the ureter ought always to be treated separately and Mr. Knowsley Thornton is quoted as advising, in addition, the suturing of the end of the ureter to the lowest part of the wound, especially, I take it, where the kidney is removed by the abdominal method. I do not know if he advises it when the operation is performed by the post-peritoneal method. That there are conditions of kidney met with, for which the operation of nephrectomy is performed, which point to the operator the wisdom of treating the ureter as a separate entity I do not wish to deny, but that it is unnecessary to do so in all cases is, I think, amply demonstrated by this one. The evil results of a leaking ureter were conspicuous by their absence.

Reviews and Notices of Books.

Sexual Dimorphism in the Animal Kingdom: a Theory of the Evolution of Secondary Sexual Characters. By J. T. CUNNINGHAM, M.A., formerly Fellow of University College, Oxford. London: A. and C. Black. 1900. Pp. xi + 317. 32 Illustrations in the text. Price 12*s.* 6*d.* net.

MR. CUNNINGHAM could hardly have selected a more important and entrancing subject upon which to write a book than a consideration of the various problems involved in what is generally called "sexual selection." So obvious is this that he need hardly have adopted so deprecatory a tone in the preface as he has thought fit to adopt. Mr. Cunningham writes: "It is true that many interesting and valuable observations have been made, but as the description of the *behaviour of a living animal adds so much less to a man's* reputation than an anatomical or systematic research the study of habits makes slow progress." The precise opposite appears to us to be the case. There is most unquestionably at the moment a "boom" in bionomics and a decided "slump" in purely anatomical or embryological investigation. The former is not to be regretted, but the latter to our mind is a retrograde step. The professional zoologist is apt to resemble the religious convert, he lives for half his life in crass ignorance that a certain line of work is a possibility and desirable; when he wakes up to the fact he begins by insolent denunciation of other zoologists who prefer other paths. In the palmier days of "section cutting" and "morphology" the systematist was contemptuously treated as was even the anatomist who followed the methods of Cuvier and of Owen. Now we study the influence of temperature upon development and feed birds with gaudily coloured caterpillars. An excellent thing, too, but not to be studied to the exclusion of everything else. If Mr. Cunningham will do once again what he has doubtless often done before—walk into the central hall of the Natural History Museum—he will find bionomics to any amount and will revise the sentence in his preface to which we have referred.

The question arises in considering Mr. Cunningham's book, important and fascinating though the subject is, are there sufficient facts and inferences which have accumulated since the time when Darwin wrote "The Descent of Man" to justify a review of the subject of sexual selection? Perhaps it is easier now than it was some years ago to treat sexual selection from the point of view of destructive criticism but it does not appear to us that a replacement of that theory is yet possible and least of all by a theory so purely Lamarckian as that in which Mr. Cunningham believes. As to the first point such advances as we have made in the knowledge of fact seem not to have strengthened the evidence for sexual selection; but it does, as it appears to us, seem to be a fact incapable of refutation that "preferential mating" occurs in the vertebrate world. *The classical instance of the latter* marriage custom is, of course, "the old pied cock" of Darwin whom the hens preferred to his more attractively coloured and youthful rivals. The two theories are sometimes confounded, but the one has not necessarily anything to do with the other. They may obviously coincide; but this emphatically remains to be established. However, this attitude of mind does not really affect the position taken up by the author of the volume before us. Mr. Cunningham dwells upon the fact that sexual differences of colour and structure other than of the parts concerned in reproduction, are the outward effects of a different mode of life and are at least often caused by direct stimulation of a special kind. To do Mr. Cunningham justice he is not in the least afraid of the inconveniently "tight" places in which the pursuit of his views at times lands him. He has in an eminent degree the courage of his opinions. In dealing, for example, with the marked differences which the two sexes of certain butterflies exhibit, he boldly leans for support upon *the first of the two articles of his creed.* It is a commonplace of zoology that many butterflies (and of course, other animals) closely resemble other species of butterflies to which they are or are not closely related. In many cases this resemblance is limited to one sex, which is then most commonly the female. Mr. Cunningham instances the swallow tail butterfly (*Laertes pammon*); this insect has two kinds of females; the females are, as it is said, "dimorphic." One kind of female imitates another swallow tail (*Menelaides aristolochiæ*), the other a second species of the same genus (*M. hector*). The male imitates neither, but bears carelessly his own peculiar characteristics. Now it is held by the advocates of the theory of "mimicry" that the female escapes destruction by this striking likeness to the nastily tasting *M. aristolochiæ* and its ally. They would add that it is more important that the female should be protected than the male, since upon her devolves the duty of egg laying. When the male has once paired with his mate natural selection has no further interest in him and does not care what becomes of him. Mr. Cunningham attacks this view in a fashion which is not without ingenuity. Why, he asks in effect, should not the male also get to be a mimic? Although it may escape by its activity, why should not it also add to its defences by an imitation of a protected *Papilio?* If selection were the only factor, then thinks Mr. Cunningham, the male would undoubtedly be affected like his mates. "On the theory," concludes the author, "that the similarity of habits between the female and the mimicked species was the cause of the mimicry, the facts at once become intelligible; on the theory of selection they do not." Now it must be conceded that this line of criticism is most damaging to those who are convinced of the adequacy of the theory of mimicry, for the reason that according to most of that party variation is taking place in all directions. But the innate fallacy in that view, and in Mr. Cunningham's criticisms thereof, seems to us to be the assumption that variation does occur in this *radiating way.* Facts of breeding, and other natural facts prove more and more conclusively every day that variation—whatever be its cause—does not proceed in every direction but along definite and circumscribed paths.

Mr. Cunningham has a wider knowledge of the facts of zoology than many who have attempted to write works of a general character like the present. But like most zoologists Mr. Cunningham is not a specialist in every group. In stating that the horned screamer (*Palamedea cornuta*) has two pairs of spurs upon the wings the author is in error; nor is he accurate in stating that the pendulous fleshy process on the head of the turkey is erected when the animal is "love making." The "anseres" are not the only birds with two pairs of extrinsic muscles upon the trachea; there is, moreover, no family cygnidæ which can be distinguished from the *other anatidæ.* The latter criticism may be, perhaps, thought pedantic, but it is not pedantic to remind the author that chamæpetes does not belong "to the turkey family." Mr. Cunningham's own special knowledge relates mainly to fishes, upon which group he has published much in the way of valuable research; when he deals with this group he is more illuminating than he is at times elsewhere. It is generally quite possible to deal with philosophical speculation from a knowledge of one group only; we wish much that this plan were more usually adopted. With the critical destructive part of Mr. Cunningham's work we are as a rule in sympathy. He points out, for instance, a real difficulty to the believer in selection pure and simple in treating of the specific characters of certain fishes. The plaice has red spots and smooth scales with a bony ridge behind the eyes elevated into five tubercles. The dab, on the other hand, has spiny scales, while the flounder differs from both in its small and reduced scales accompanied by other scales which are specially enlarged; and the ridge behind the eyes is smooth. How can we account for these specific differences on any theory of utility, he asks; and as in countless other cases there appears to us to be no answer possible. It would be wiser, we think, to let the matter rest here for the present, but Mr. Cunningham must have a theory, and naturally dwells upon the different kind of life led by the three species of flat fish.

Elsewhere the author is to our mind too anxious to press his views of the close relation between certain habits and concomitant structural peculiarities. To arrive at the conclusion that the complexly branched horns of deer are the result of the habit of butting each other shown by the males is too difficult of acceptance; worse still from the point of view of probability—and what other arguments are there at present?—is his opinion that the grooves on the adorned snout of the mandrill are the results of continued clawing at each other by quarrelsome males. We cannot accept his assertion that the manes of lions, the long feathers of certain birds, warts and combs, are merely due to increased growth caused by pulling and pecking at those spots. In short, while Mr. Cunningham possesses a pleasant and fluent style and has furnished us in this book with many interesting and often little known or absolutely novel points, and has attacked the standpoint of those who believe in sexual selection with much acute criticism, we cannot allow that he has replaced that theory by one which is more convincing. As he admits himself, we require more study and the accumulation of much more fact; the time has not yet come for even the most tentative generalisation.

A Text-book of Practical Obstetrics. By EGBERT H. GRANDIN, M.D., and GEORGE W. JARMAN, M.D. Third edition, revised and enlarged, with 52 full-page Photographic Plates and 105 Illustrations in the text. Philadelphia: F. A. Davis Co. 1900. Pp. 526. Price $4.00.

THIS book has reached a third edition in a comparatively short space of time. From this we may infer that it is appreciated by American students. In our notice of the second edition we pointed out what we considered some of its defects. One of the most important in a book of this character intended for ready reference is the difficulty experienced in finding any connected account of the treatment recommended for varying conditions. This is due firstly to the fact that the index is a very poor and incomplete one and no attempt seems to have been made to improve it, and secondly, to the plan adopted of relegating without adequate cross references the descriptions of the operations of obstetric surgery to the second half of the book, away from the account of the different conditions in which they may be required. We should much like to know upon what number of cases the authors base their statement that in the treatment of placenta prævia "the elective emptying of the uterus enables us to save nearly 90 per cent. of the infants instead of losing this number, as was the record of the past, and the chances of the woman's life being saved may be placed at about 98 per cent." We are surprised to find no notice at all of Champetier de Ribes's bag and the old-fashioned, we had thought obsolete, pattern of Barnes's bag figured and apparently recommended. The authors appear to consider the exceptions to Colles's law as sufficiently numerous to warrant the prohibition of nursing by a healthy mother of a congenitally syphilitic infant and the suckling of a child born without evidence of disease by its mother for fear it may become infected.

For the experienced practitioner able to pick out the good from the bad no doubt the book contains some useful information, but at any rate for the English student we do not feel that we can recommend the third edition any more than we did the second.

A Treatise on Plague: The Conditions for its Causation, Prevalence, Incidence, Immunity, Prevention, and Treatment. By Major GEORGE S. THOMSON, M.B., M.Ch., M.A.O. R.U.I., I.M.S., Bombay; and JOHN THOMSON, L.R.C.S., L.R.C.P. Irel., Special Plague Officer under the Government of Bombay. London: Swan Sonnenschein and Co., Limited. 1901. Pp. 308. Price 7*s.* 6*d.*

THIS volume, which consists of nine chapters and a few pages devoted to Pest Bibliography, after dealing with such subjects as the definition and etiology, historical retrospect, and incidence of plague, proceeds to the consideration of the relation of rats to the pest, the mode of infection in plague, and the use of chemical disinfectants, with a description of the plague epidemic in Satara city, Mr. Haffkine's prophylactic inoculation, and the reports, statistical, clinical, and otherwise, of the Parel plague hospital.

The authors, it will be seen, have a wide field and a large amount of information and material at their disposal, in addition to that which has been acquired from considerable personal experience; and from what may be termed a practical common-sense point of view they have a good deal to say which is deserving of, and commends itself to, attention.

Their treatment of the subject, while it evinces an up-to-date acquaintance with the results of scientific researches, is nevertheless not perhaps so terse and precise as could be desired. It contains a great deal of information, but it is too discursive in style and arrangement and the book does not readily lend itself to analysis and review. We take it, however, that one of the main objects aimed at being proved is made plain enough, and it may be described as something to this effect: that although a micro-organism is the origin and cause (the seed) of plague, as of some other infectious epidemic diseases, it requires a suitable soil and environment for its life, growth, and development. That, in other words, every seed or germ of disease requires, like a vegetable seed, a suitable muckheap or soil for its preservation and growth and that it is often far easier to prevent or to deal with the muckheap than with the seed itself.

"The practice of classifying diseases mainly by the micro-organisms that give rise to them confers on the germs," say the authors, "a wholly factitious and overwrought importance, has caused us to pay less regard to the secondary controllable causes, equally, if not more important. ...... In nature whatever is, is so under certain conditions, some of which are accidental, while others are essential. The difference must be carefully ascertained." The authors allege that the germ has become the dominant process in disease, and the theory overdriven has become a bar to medical progress and true preventive science. They contend that the dreaded scourge of plague can be resisted and stamped out by proper sanitary precautions alone in a sensible manner, based on the true theory of its causation. Experience has proved that the contagion of plague, when diluted with pure atmospheric air, becomes innocuous to those in close contact with the afflicted. The preventive measures are cleanliness, prevention of overcrowding, and perfect ventilation.

The unfortunate thing connected with public hygiene, however, is that whilst the principles by which we should be guided are generally recognised their application in practice is another matter. Other considerations of a more or less prohibitive nature come in and assert themselves, and peoples—especially Eastern peoples—and governments are only too ready to run the risk of being devastated by epidemics rather than to incur the financial and other sacrifices which preventive measures entail. This is so well known that to assert it even has become a platitude. To an uneducated and conservative laity the only interest attending the discovery of a specific microbe is the hope of its immediate destruction or, failing that, the limitation of its spread by measures of quarantine; the former frequently cannot be accomplished and the latter, besides being impracticable and ineffective, often costs more than the provision and execution of obvious sanitary requirements would have done. Practically we have in the meantime to put our main reliance in the case of plague in the East on prompt evacuation of an infected house or locality and prophylactic inoculation against the disease. Without going into all the details set forth in this volume we may say, in conclusion, that this treatise on plague is written from a practical and independent standpoint and containing, as it does, a large amount of information and a record of the results of personal experience on the part of its authors is well worth reading.

Les Processus Généraux. By A. CHANTEMESSE and W. W. PODWYSSOTSKY. Vol. I. of *Pathologie Générale et Expérimentale.* Edited by C. NAUD. Illustrated. Paris: G. Carré et C. Naud. 1901. Pp. 420.

THIS volume, which deals with certain of the general processes of pathology, is the first of a series which will ultimately include all branches of the science which are concerned with what is strictly called general pathology. The volume commences with an account of the morphology of the cell and with the propagation, course, and termination of disease. It then discusses the influence of heredity on the determination of morbid processes and proceeds to a full account of the various degenerations and atrophies.

Although one of the authors—namely, Professor Podwyssotsky—has already published in the Russian language a work dealing with practically the same departments of pathology the present volume is by no means a translation. The text has been entirely rewritten and extended and the illustrations, which constitute a most important feature of the work, are nearly twice as numerous as in the Russian work of Professor Podwyssotsky. As the authors are at pains to make clear in the preface, the reader must be prepared for a more strict interpretation of the term "general processes" than is usually accepted by authors of works on general pathology. Thus they admit that they can draw no sharp distinction between the processes of life which are usually called physiological and those which are usually called pathological. Both of them represent the reaction of the organism to variations in its environment. For this reason the term "pathological physiology" might have been adopted as an alternative title for a work which deals almost as fully with physiological processes as with those which are distinctly within the borderland of pathology. A very fruitful attempt has been made to systematise the morbid processes which are dealt with in this volume according to a rational and genetic classification. The degenerations are shown to be variations of certain more or less similar types which start as simple coagulation of protoplasm (granular degeneration) and proceed through various stages of chemical disintegration until in carbohydrate degeneration (glycosuria and diabetes mellitus) we find protoplasm completely broken down into two *moieties*, a carbohydrate- and a nitrogen-containing half. Hyaline degeneration is considered as a precursor of amyloid degeneration and mucoid as a transitional stage between albuminoid and carbohydrate. In mucoid degeneration there is a liquefaction of albumin with a modification of its chemical composition, whereby the carbohydrate molecule, instead of being set free as in carbohydrate degeneration, is united loosely to an albuminous substance. The relationship between fatty and carbohydrate degeneration is again close, and has this common feature, that in both cases fixed albuminous bodies become transformed during life into bodies which contain no nitrogen. These two forms of degeneration frequently are associated. Although the correlation of these morbid processes is intensely interesting the authors have not allowed themselves to be carried away by merely theoretical considerations. They admit the difficulties and point out the many hiatuses which must be filled in before any classification can be complete.

Closely associated with the question of degenerative processes is the subject of the unorganised ferments of internal secretion. Obesity with diminished combustion of fat may in certain cases be associated with a deficiency of a ferment called lipase which is contained in the blood and has the power of splitting fat into a glyceride and a fatty acid. The extent to which fat can be utilised in the system (limit of utilisation or coefficient of assimilation) may be dependent on the activity or quantity of this ferment, in the same way that glycolysine (Lepine's sugar-splitting ferment) may determine the limit of utilisation of sugar. On the degree of activity of these ferments, which can be measured, it may ultimately be possible to base a more or less trustworthy prognosis in certain cases of obesity and diabetes.

In the chapter which deals with Heredity there are a number of points of extreme interest. The authors accept as established the doctrine of the transmission of acquired characteristics, both physiological (transformism) and pathological (disease). It would appear that a habit of metabolism is the essential feature which is transmitted. This may ultimately conduce to morphological variation. Lowly organisms such as bacteria, which may pass rapidly through many generations, afford the best subjects for inquiries of this kind.

The illustrations, which, as we have before mentioned, contribute in no small degree to the value of this book, are, for the most part, exact reproductions in colours of the original sections which have been prepared mostly by Professor Podwyssotsky according to the most modern and approved histological methods. As a series they are altogether superior to any other with which we are acquainted.

If the high standard of excellence which characterises this the first volume is maintained in those which are to follow this general pathology will be unparalleled as a work of reference

---

LIBRARY TABLE.

Practical Hints on the Erection of Baths and Wash-rooms for Public Use and in Factories, &c. Illustrated London: Messrs Andrew and Suter. Pp. 30.—The principal object of this pamphlet is to bring into notice a patent counter-flow water-heater which has only recently been introduced into the English markets, although in Germany, where it was invented, and in the United States of America it has met with favourable acceptance for some time past. The heater consists of a small bundle of copper tubes inclosed in an iron jacket. The supply of water to be heated enters this jacket at the bottom and is controlled by a valve; a second valve admits steam, either direct from a boiler or the exhaust steam from an engine, to the bundle of inner tubes at the opposite direction to the cold supply, and this steam valve is so arranged that it cannot be opened before opening the cold-water valve. A thermometer is fitted to the supply-pipe from the heater to the bath to guide in the regulation of the steam valve, so as to ensure the heating and maintenance of the water at any required temperature according as the steam pressure may vary in the boiler. By this means any chance of over-heating is avoided. The pamphlet illustrates a number of schemes to show how mines, factories, &c., may be fitted at a comparatively small cost with the means for the personal cleanliness of the employés, whether in large or small numbers. Without criticising the several proposals in detail it may be stated than the plans and suggestions have evidently been carefully considered with a view both to efficiency and economy. Any scheme that tends to promote the personal cleanliness of those engaged in manual labour, amidst surroundings not only of a dirty but often of an unwholesome character, is not only a matter of vital importance to the individual worker, but is a boon to the community at large. It is a matter for surprise that the necessity for suitable washing accommodation is not more generally recognised by employers. Seeing that cleanliness tends to health, the producing power of any individual must be raised or lowered as his or her health may rise above or fall below the normal standard. This fluctuation, where many hands are employed, must obviously greatly influence production. We understand that an installation has already been fixed for the Leeds Corporation and doubtless many users of steam-power will avail themselves of the opportunity to promote the comfort and well-being of those under their charge.

Walley's Practical Guide to Meat Inspection. With Illustrations. Rewritten and enlarged by STEWART STOCKMAN, M.R.C.V.S. London and Edinburgh: Young J. Pentland. 1901. Pp. 281.—That Walley's "Meat Inspection" is a work which has been fully appreciated is shown by the fact that it has reached a fourth edition. It is the accepted text-book of those whose duties involve the inspection of flesh used for food, and, indeed, it may be said to be the only trustworthy work of its kind in the English language The method of inspection of carcasses is carefully dealt with, each individual part being taken and described in detail, and the differences are explained between the appearance of the organs of each species of animal. A chapter is devoted to the methods of preparing specimens for the microscope, including the processes of freezing, embedding, cutting, and staining sections. The appearances of diseased flesh are illustrated wherever possible, as are also the bacilli which cause tuberculosis, anthrax, swine fever, tetanus, and other affections. The chapter on Bacillary Diseases is very full and complete, as is also that on Diseases caused by Animal Parasites, and the book concludes with a chapter on Food Poisoning in Man. The fourth edition has been rewritten and brought up to date by Mr. Stockman, M.R.C.V.S., professor of pathology and lecturer on meat inspection in the Royal (Dick) Veterinary College, Edinburgh, and we can with every confidence recommend it to medical officers of health and veterinary inspectors.

JOURNALS AND MAGAZINES.

The Medical Guild Quarterly.—This, the organ of the Manchester Medical Guild, contains in its July number a most interesting article by Mr. Colin Campbell of Saddleworth. The article is headed "The Parish Doctor and Out-door Medical Relief." Mr. Campbell points out how in most places the parish medical officer works under great disabilities. He works under contract and has no stimulating competition to meet. He is often only called in as a last resource, and that, too, in the middle of a long and acute illness, a change of practitioners being made, which is unfair to both practitioners and to the patient. Often, too, the poor will not call in the parish medical officer as a private medical attendant lest they may be suspected by their neighbours of receiving parish relief. The Saddleworth system, which appears to be an excellent one, is as follows. Every registered practitioner in the district who desires it is appointed a district medical officer, "consequently there is no one parish doctor, and poor persons can obtain medical relief from any doctor they desire." The Saddleworth Guardians, acting on the principle of *obsta principiis*, grant medical relief orders before a state of destitution arrives and do not dub an honest man a pauper simply for the crime of being out of work. We commend the Saddleworth method to other unions.

The Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, F.R.S., D. J. CUNNINGHAM, F.R.S., G. S. HUNTINGTON, M.D., A. MACALISTER, F.R.S., and J. G. M'KENDRICK, F.R.S. Vol. XXXV. New series, Vol. XV. Part 4. July, 1901. With Plates and Figures in the text. London: Charles Griffin and Co. 1901. Price 6*s.*—This part contains the index to the thirty-fifth volume of the journal and the following articles:—1. The Natural Subdivision of the Cerebral Hemisphere, with five diagrams, by Professor G. Elliot Smith, which is an elaborate and successful effort to clear up the confusion at present existing in regard to the nature of the "pallium" which properly includes three structural elements, a ventral part or pyriform lobe, the basipallium, the marginal pallium or hippocampus, and lastly, that large dorsal cap the dorsipallium or neopallium. He goes on to say that if "we regard this term 'neopallium' as the complement of 'rhinencephalon' it will involve a new definition of the latter, which would then include the whole pyriform lobe, the whole hippocampal formation and paraterminal body, in addition to the olfactory bulb, peduncle and tubercle, and the locus perforatus." Professor Smith regards the neopallium as the *sensorium commune*, where the various sensory impulses meet and react upon one another. 2. On Professor Pearson's Contributions to Osteology, by Robert Worthington, B.A., Clare College, Cambridge. This article gives the relations of mathematics to anthropology. 3. The Effect of Thyroidectomy upon Nitrogenous Metabolism, by J. Herbert Parsons, F.R.C.S., Sharpey research scholar. The effects are shown to be slight. 4. A Case of Hereditary Brachydactyly, by T. Law Webb, M.R.C.S. Eng., with two plates. 5. Note on the Superior Tibio-fibular Joint, by S. A. Owen, Trinity College. The author describes an intra-articular lamella as existing in 70 per cent. of the specimens examined. 6. Report of a case in which there occurred an Anomalous Structure at and about the Base of the Bladder, by H. T. Thompson, Christ's College, with a woodcut. The author supposes the structure described to be the lower ends of the ducts of Müller. 7. An Anomaly of the Omohyoid, by J. Ernest Frazer, F.R.C.S. Eng. 8. Double Left Parietal Bone in a Scottish Skull, by Professor Sir William Turner. 9. Eleventh Report on Recent Teratological Literature, by Bertram C. A. Windle, F.R.S. Lastly, the number contains the Proceedings of the Anatomical Society of Great Britain and Ireland.

Annals of Ophthalmology. Vol. X., No. 2, April, 1901. Managing Editor, H. V. WURDEMANN, M.D. St. Louis, Mo., U.S.A.: Jones H. Parker. Price 18*s.* per annum. Published quarterly. — The following articles are contained in this number:—1. Exophthalmos, the result of an Osteoporosis, by P. N. K. Schwenk, M.D. Philadelphia. 2. Myosis and Ptosis resulting from a Gunshot Wound Paralysing the Cervical Sympathetic, by George C. Harlan, M.D. Philadelphia. 3. New Test Types for Determining the Acuteness of Vision, by Edmund Landolt, M.D. Paris. 4. Evisceration without the Necessity of wearing Artificial Eyes, by J. G. Huizinga, M.D. Chicago. 5. A Series of Demonstration Lenses intended for Teaching Purposes, by Charles A. Oliver, M.D. Philadelphia. 6. The Economic Valuation of Vision, by H. V. Wurdemann, M.D. Milwaukee, Wis., with the collaboration of H. Magnus, M.D. Breslau. Lastly, the part contains abstracts by Charles May, M.D., of English and American ophthalmic literature, by Frank Allport, M.D., of English colonial literature, and by other surgeons and physicians of the ophthalmic literature of Germany, France, Italy, Spain, Portugal, Russia, Austria-Hungary, and Holland.

The *Practitioner* has for the main topics of the August number the treatment of fractures, particularly as regards the early use of massage and passive movement, and the value of Roentgen rays in the matter of fractures. Mr. H. H. Clutton's article on the Influence of X Rays on the Diagnosis and Treatment of Fractures should be read by every practitioner, it is full of sound advice with which to temper a blind faith in the indiscriminate infallibility of the rays in questions of diagnosis. Mr. Clutton concludes that for routine examination of common and uncomplicated fractures there is little to be gained from use of the rays, but that for exceptional cases of difficulty this is of paramount importance. Such use may save a patient pain and anxiety and enable a surgeon to arrive at a definite diagnosis without much manipulation. At the same time certain disadvantages are to be borne in mind, the chief of which is the ease with which fallacy arises through inexperienced interpretation of a skiagram or through too limited application of the rays when the truth can only be reached by means of photographs from several aspects. Sir William H. Bennett writes on the advantages of Massage and Early Movement and arrives at the conclusion that with ordinary discretion and average dexterity the result of the method is advantageous, the time elapsing before a patient is fit to resume his vocation being diminished at least one-third. Mr. C. H. Golding Bird discusses the treatment of Simple Fracture, particularly as regards the question of open operation. His views are not of the extreme order and are well supported by sound argument. An article devoted to the subject of Fractures of the Upper Extremity is from Mr. J. E. Platt of Manchester. The editorial remarks upon the British Congress on Tuberculosis include some severe criticism of what is described as Professor Koch's "*coup de théâtre*." He is censured for working a "boom" and running a "sensation." The *Practitioner* does not scorn the vocabulary of less dignified and more frequent periodicals.

The *Medical Magazine* for August is largely occupied with the British Congress on Tuberculosis, which we have already dealt with too fully to permit of any useful description of the articles reproduced in the magazine. Dr. George Heaton contributes an article on Blood Examination as a Clinical Guide in Cases of Obscure Suppuration, with Cases, but does not, we think, make out a very strong case for the method which he advocates. In comparatively mild cases of appendicitis where there is for days doubt as to the presence or not of pus the blood count seems to be of more service than in any other class of case. Leucocytosis is common to so many different conditions that the question of diagnosis must be by other means narrowed down to a small limit of doubt before blood-count helps us much. Mr. J. Foster Palmer concludes his series of articles on Modern Epidemics with some philosophical reflections upon the ultimate causes of disease in general and some worthy admonitions in respect of the "medical ideal."

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague Epidemic.—The Pasteur Institute at Kasauli.—"Epidemic Dropsy" in Calcutta.

AN increase of 457 is reported this week in the number of plague deaths throughout India, the total being 1912 as against 1455 for the week previous. The Bombay Presidency showed a rise from 1174 to 1643, the worst district being Belgaum with 467 deaths. The State of Kolhapur had 390 deaths, and Dharavi 474 deaths. Bombay city returned 106 and the State of Mysore 154 deaths, but elsewhere the mortality was unimportant.

Since its foundation last year I have had occasion to record from time to time the very favourable results which are being achieved by Major D. Semple, R.A.M.C., at the Pasteur Institute at Kasauli. No less than 286 patients have been under treatment during the past 11 months. The army has benefited very largely, as 19 British officers, one warrant officer, and 57 British soldiers have been saved a journey to Paris and have successfully gone through the treatment. Caste prejudice is being gradually broken down and the benefits of the institute are being sought for by all classes. In several instances one or two patients have come from places where five or six persons had been bitten by the same rabid dog or jackal and are now alive and well, while those who remained in their village have died from hydrophobia. Other work is also being done at the institute. Anti-typhoid serum is being prepared, and the diagnosis of typhoid and Malta fevers by the serum test is being undertaken. Quite a little school of bacteriology is being started, and several medical officers are working in the laboratory. There is still much to be done. Anti-venene ought to be turned out in comparatively large quantities instead of having to be procured from Lille at great cost. Anti-tetanic serum, again, is urgently required, but more funds are wanted to provide horses and stables. Tetanus is so very common, both amongst men as well as beasts, that immense benefits could be conferred by the establishment of a ready supply. The success of the institute not merely justifies but demands immediate support on the part of the Government.

Several series of cases which have been described under the title of "epidemic dropsy" have lately occurred in Calcutta. The symptoms consist of œdema of the legs, purpuric eruptions all over the body, fever of a mild type, intestinal catarrh, pain in the limbs and abdomen, slightly jaundiced condition of the eyes, and extreme prostration. The illness has lasted in several cases for over a month. The outbreaks have occurred in groups of families and in a girls' college. In one published case the urine was albuminous and dark red in colour and it contained blood and hyaline casts and a large excess of urates. It is said that a similar series of cases occurred in the year 1878-79 and that they are described in the report of the Calcutta Medical Society for 1880, but no special cause for the disease could at that time be made out. Many of the cases proved fatal, but no deaths this year have as yet been reported. The disease is being investigated by the health officer and by the pathologist to the Medical College Hospital, but it is somewhat premature at present to formulate any opinions.

August 3rd.

COCAINE POISONING.—At Cromer on July 24th an inquest was held on the wife of a pharmaceutical chemist, death having been caused by injections of cocaine administered with a view to the extraction of teeth. The operator was a medical student, an assistant to the deceased's husband. He prepared the solution, gave the injection, and extracted one tooth without much trouble. Deceased, who had previously had cocaine injected by a dentist without any ill effects, insisted on having another injection for the extraction of the second tooth, and convulsions soon afterwards set in. The assistant stated that he dissolved one grain of cocaine and gave it in three injections. He had been in the habit of administering cocaine. Two medical men who [illegible] Movement of the he[illegible] was very slow and [illegible] the pupils were dilated. Artificial respiration was used and restoratives were given, but death took place in about half an hour. No unusual appearances were found at the necropsy.

THE LANCET.

LONDON: SATURDAY, AUGUST 24, 1901.

Dr. Ravenel on Human and Bovine Tuberculosis.

AT Congresses bane and antidote flourish side by side; free expression of opinion makes for truth; and Professor KOCH said well, at the British Congress on Tuberculosis, that all he wished to get at was the truth. Had Professor KOCH'S address not been given Dr. RAVENEL'S paper, published in our columns,[1] valuable as it is, might have been allowed to pass without attracting the attention that it deserves, and, like other evidence hitherto brought forward in the same direction, might have been dismissed as proving what had already been proved. This would have been a great loss, for we have in it evidence of an exceedingly striking character such as is seldom collected into one paper. It is specially valuable at the present time as following up Dr. THEOBALD SMITH'S work. Much of Dr. RAVENEL'S work runs parallel with certain of the work reported by Professor KOCH and corroborates many of his statements based thereupon. At one point, however, diverging from Professor KOCH'S conclusions, most convincing evidence is adduced to show that some fallacy must have crept into Professor KOCH'S experiments, his observations, or his arguments. At the outset Dr. RAVENEL, in agreement with many other workers, comes to the conclusion that there is usually some slight difference in the morphological characters of the bovine tubercle bacillus and the human tubercle bacillus. Further, as the result of a series of well conceived and carefully executed experiments he is of opinion that the human tubercle bacillus is less virulent for most species of animals than is the bovine bacillus. In the case of pigs this general statement does not appear to hold good, as the human bacillus seems to induce death and extensive tuberculous lesions in these animals at least as early as does the bovine bacillus. There appears, however, to be little doubt that where cattle are concerned this difference is at high-water mark and that it is an exceedingly difficult matter to produce tuberculosis in cattle with the tubercle bacillus of human origin. The converse, Professor KOCH maintains, may hold good, though from Dr. RAVENEL'S experiments this appears to be by no means probable; indeed, we should expect, as pointed out by several workers, that a bacillus that is pathogenic for such a large number of species as the tubercle bacillus of bovine origin, if intensified in virulence for one species would probably be intensified for the others. This, of course, does not necessarily follow, as examples are recorded of an organism becoming more virulent for one species and less so for another; but even so it is usually an easy matter for the organism to regain its virulence for a species to which for a time it appeared to be temporarily innocuous. As Professor MCFADYEAN pointed out, there is no micro-organism at present known that is pathogenic in three distinct species of animals which is not also pathogenic in man. The bovine tubercle bacillus, as we have seen, is pathogenic in a very large number of widely diverse species; it is even more pathogenic in these than is the bacillus from the human subject: we should expect, therefore, *a priori*, that it would also be more virulent for the human subject.

At present there is not much direct evidence on this point, but a few well-authenticated cases of a disease which is developed so slowly as tuberculosis, and of which the proof is so difficult, are of enormous value in this connexion, outweighing all the negative evidence that can possibly be brought forward on the opposite side. Dr. RAVENEL has three such cases in which the evidence is clear and well authenticated. He has recovered the tubercle bacillus from one case in which the inoculation was undoubtedly from a bovine subject, another of the cases succumbed to the disease, and in all three cases the veterinary surgeons engaged in handling and treating the tuberculous bovine subjects seem to have incurred inoculation wounds. No doubt in due course other cases will be recorded, but the great value of these is that they are reported at the "psychological moment" and have done more to strengthen the hands of those who are dealing with the question of the prevention of tuberculosis by paying attention to tuberculosis amongst cattle than would hundreds of cases reported at an earlier date or after interest in the subject had evaporated.

It is evident that mixed infection may play a most important part in determining an attack of tuberculosis. We know, for example, that under certain conditions the tetanus bacillus is incapable of inducing an attack of tetanus whilst under others the same organism may prove most effective, and we are gradually coming to understand the conditions under which this takes place; the presence of other septic organisms, of other comparatively innocuous organisms and even of such substances as lactic acid may be sufficient to turn the scale against the tissues and in favour of the tetanus bacillus, with the result that an attack of tetanus may be induced. The action of the erysipelas coccus may be enormously increased by the presence of such a comparatively inert organism as the bacillus prodigiosus, and it will be gathered from Professor CROOKSHANK'S experiments that a mixed infection may have had something to do with the extent and distribution of the tubercle bacillus in his experimental case of tuberculosis produced in a calf by the intra-peritoneal injection of human tuberculous sputum. As has long been pointed out, the tubercle bacillus may be present in the alimentary canal of healthy individuals without giving rise to tuberculosis. On the other hand, tuberculosis is never present without the presence of the tubercle bacillus. Going a step further, it is recognised that it is specially in children who have some disturbance of the alimentary canal that mesenteric tuberculosis is most frequently met with. In fact, the conditions necessary for the invasion of the tubercle bacillus, and even the clinical symptoms associated with tuberculosis, are frequently those of a mixed infection

---

[1] THE LANCET, August 10th (p. 349) and 17th (p. 443), 1901.

It is evidently very important that we should continue our study of the tubercle bacillus Professor Virchow and Dr Klein have all along maintained that there are distinct morphological and pathogenic differences between the bovine and the human tubercle bacillus These differences may be, and probably are merely varietal We can as yet, scarcely come to the conclusion that they are specific, indeed, all the evidence yet obtained goes strongly against such a supposition Even in the much debated question of small pox and vaccine as Lord Lister points out Dr Copeman has been able to prove that small pox cannot be transmitted to the calf directly but it can be transmitted to the monkey, whilst from the monkey the virus appears to be sometimes transmissible to the calf and then in the child it produces a condition indistinguishable from that produced by vaccine matter

As regards the appearance of a local lesion at the point of invasion, numerous experiments have been carried on with the object of determining whether this always takes place or not Delépine Sidney Martin, Sims Woodhead, McFadyean, Shennan, Still, and other workers in this country are satisfied that the altered lymphatic gland *rather than any lesion of the free surface* indicates the seat of invasion. Anyone who will make a large series of inoculations cannot but be struck by the fact that it is not the point of infection that suffers in the invasion of tuberculosis, but the nearest lymphatic gland Even in typhoid fever, where the lymphoid tissue comes so near the surface it is only after marked alterations in the lymphatic tissue have taken place that ulceration occurs, and there are cases of typhoid fever in which ulceration practically never ensues Indeed it is only because of the presence of the lymphoid tissue in the alimentary canal mucosa that a local lesion is developed—and this, it may be remarked, in a disease in which the degenerative processes go on very much more rapidly than they do in the case of tuberculosis Most people therefore will be inclined to accept Dr Ravenel s statement that a certain proportion of cases of infection of the alimentary canal by the tubercle bacillus gave not the slightest evidence of any local lesion at the primary seat of infection, and that those cases in which there is infection of the mesenteric glands only are probably the result of infection by the tubercle bacillus—sometimes, no doubt the bacillus from the human subject, but in young children during the milk taking period of their life more frequently the bacillus from a bovine source

The matter cannot be allowed to rest The Government authorities in Germany are apparently so thoroughly convinced of the importance of this question that they are determined to sift it to the very bottom and it is to be hoped—although numerous enthusiastic workers will probably take up this question in order to gain information—that a Royal Commission will be appointed by our own Government to investigate the question thoroughly Should such a commission be appointed it is very desirable that the members should be invested with full powers to carry out inquiry in all directions.

Nursing in Workhouse Infirmaries.

The question of efficient nursing in workhouses and infirmaries is one of the highest importance, whether considered from the point of view of economy or approached on purely humanitarian grounds. Regarding the question on the lower basis, it has been stated that the detection of malingerers and the prompt and proper treatment of disease by thoroughly good nursing would probably save half the present sums expended upon the sick in door pauper If this statement is approximately correct it is surprising on the face of it that over 50 years had elapsed since the Local Government Board had made any reforms in workhouse nursing when on August 6th, 1897, they issued an Order the principal provisions of which were —firstly that no pauper inmate should be employed to perform the duties of nurse in the sick or lying in wards secondly that no person should be appointed to the post of nurse or assistant nurse in the workhouse without having had such practical experience as might render her a fit person to hold such office, thirdly, that when the nursing staff consisted of three or more nurses there should be a superintendent nurse appointed, and fourthly that it should be the duty of the master of the workhouse to engage additional nursing assistance upon receiving a *requisition from the medical officer that it was* required The special attention of medical officers of workhouses should be given to this last provision because from *facts which have come to our notice* it is to be feared that the valuable power placed by it in the hands of the medical officer of a workhouse has sometimes been overlooked It is at any rate not always brought into operation when it might be

The issue of this Order was undoubtedly largely due to the efforts of the Workhouse Infirmary Nursing Association, a voluntary association which was founded in 1879 and which has done valuable service in educating and supplying to workhouses and infirmaries some 400 properly trained nurses during the 18 years 1879 to 1897, voluntary subscriptions being collected from the public for the purpose In the latter year the executive committee reluctantly came to the conclusion that the difficulty of providing trained nurses in adequate numbers for the workhouses in England was too great to be grappled with by voluntary effort For instance, in 1895 the association could only supply 85 nurses in response to 199 applications from boards of guardians and consequently it was decided that they must cease to train and to supply nurses for workhouses. Then came the issue of the Local Government Board Order to which we have referred, and undoubtedly it was a step in the right direction The initial difficulty had been the reluctance on the part of guardians to employ properly qualified nurses, and the issue of the Order set an official seal on the desirability of adequate nursing and it intimated that the Local Government Board were both willing and anxious to pay some attention to the matter But, unfortunately the supply of nurses on the terms offered by the guardians has been totally inadequate, and the results, therefore of this Order have been largely negative It would perhaps have been well if the results had only been negative Unfortunately, in the absence of an adequate supply on the terms offered, the guardians have in many cases adopted a most pernicious system of engaging young inexperienced women under the title of "probationers" at low salaries with the promise of giving them "training." Could anything be more retrograde in the cause of good nursing or more injurious to the interests of patients, than bringing young girls into the sick wards of a workhouse without anything like systematic instruction? One of the inspectors of the Local Government Board has referred in his reports to this most serious aspect of the question. He speaks of the grave results attending the appointment as nurses of untrained women and gives examples of gross ignorance on the part of such "nurses." In one instance which he mentions a "nurse" was quite unable to take a temperature; and in another the death of a patient was attributed to incompetency to perform a duty which every trained nurse should understand. Another of the inspectors of the Local Government Board reports that "the employment of probationary nurses is on the increase, the object generally being to save expense in the way of salaries," and he speaks with disapprobation of the evils of the system at present in vogue.

An influential deputation from the Workhouse Infirmary Nursing Association waited upon the President of the Local Government Board on August 2nd, as noticed in our issue of last week[1] and pointed out the failure of the new Order to provide a proper system of nursing. It appears from the statements then made that the difficulty of obtaining trained women has increased, that many boards of guardians disregard the Order, that unqualified women are still engaged as nurses, that paupers are still employed, and that inexperienced probationers (so called) are being engaged to nurse the sick. This is not the first time by any means that the matter has been brought before the public, and we have often referred to the difficulty of obtaining a supply of trained nurses. The position is becoming more and more impossible. Nor are the causes of these difficulties far to seek. The position of nurse in the official scheme of a workhouse is not always an enviable one; the work is often uninteresting and unattractive, if not actually repellent, while the life in a country institution is dull and monotonous in the extreme. Many other extracts besides those which we have quoted from the reports of the inspectors of the Local Government Board could be given in support of the statements made by the deputation, and altogether there is a very remarkable consensus of opinion in regard to the matter. The serious defects in nursing lead to frequent cases of neglect and, as reports in the lay press reveal from time to time, to tragic consequences. As to the best method of applying a remedy considerable difference of opinion exists, but that the Poor-law nursing service, with but few exceptions, requires thorough reorganisation there can be no question. The object should be to create a permanent staff of nurses who would take a pride in the service, who would be adequately remunerated, whose position should be precisely defined, who would look forward to promotion by merit, and whose aim would be to assist the medical officers under whom they act in the alleviation of suffering, the cure of disease, and the detection of fraud.

The main responsibility for the present condition of matters clearly lies with the authority which issued the Nursing Order of 1897. It is hardly credible, yet it is nevertheless true, that the Local Government Board, with whom rests the sanction of the appointment of nurses, are constantly approving appointments which are in direct contravention of their own Order. We have rarely met with more notable instances of official self-stultification. It clearly is the duty of the Board to enforce compliance with their own Order or at least to take the initiative in seeking for and remedying the causes of non-compliance. Many of the more enlightened boards of guardians would gladly devote the money that they now waste in advertising for nurses to the maintenance of a central training school for the supply of nurses for the service. These guardians in times past subscribed to the funds of the Workhouse Infirmary Nursing Association. How much more willingly would they do so to an organisation of the same kind having official sanction? The whole question is undoubtedly an intricate one, but the solution of it cannot be much longer postponed if further public scandal is to be avoided. The matter urgently calls for the attention of the Local Government Board upon whom the responsibility rests of seeing that a uniform and efficient system of administration obtains in the workhouse infirmaries throughout the kingdom. A small Departmental Committee should be appointed to arrive at a solution of the difficulties to which we have referred. As matters now stand there exist a waste of public money, a grave defect in the care of the sick poor, a manifest injustice to nurses, and a no less manifest injustice to their patients, the sick poor. The Government must be pressed to see things in this light.

◆

The "Boiled Milk" Question.

The correspondence which has recently appeared in our columns on the subject of "Unboiled *v.* Boiled Milk" furnishes an instructive object-lesson in the want of unanimity which prevails in the minds of medical men, not only as regards the fundamental principles of dietetics, but even in their special application to the uses of the most universal of all foods.

It will not, we suppose, be seriously disputed, and we shall therefore take it for granted, that pure raw milk as it leaves the healthy gland is the most perfect form in which the maternal secretion can be administered to the offspring. We have, however, in the present controversy to consider conditions in which the maternal supply is not available, so that the issue before us practically resolves itself into two finite considerations: firstly, as to whether the dangers attendant on the use of unboiled cows' milk are, from the point of view of infection, real and substantial; and secondly, as to whether its nutritive value is seriously impaired by the usual processes of sterilisation. The first of these two questions must necessarily be approached from the widest possible standpoint, and from one which covers not only the conditions of urban and rural life but is applicable also to a large infant and invalid population. The evidence that typhoid fever, diphtheria, and scarlet fever can be disseminated through the instrumentality of the milk-supply is overwhelming, as also is the evidence that this danger is still operative in spite of numerous reforms in the methods *of distribution and administrative control*. Further than this, the rôle of the streptococcus pyogenes in the determination of disease is daily assuming a phase of greater importance, because in certain bacterial company its degree of virulence in milk is believed to become greatly intensified, and because, owing to the researches of KRUGER, of GUILLEBEAU, of ESCHERICH, of ADAMITZ, and of a host *of other observers, the severe diarrhœas of infancy and* acute gastro enteritis have been definitely connected with the presence of this organism.

---

[1] The Lancet, August 17th, 1901, p. 499.

Without entering upon the debateable question of the spread of tuberculosis by means of cows' milk it must be remembered that milk as it leaves the udder of the cow contains on the average in its mixed bacterial flora, though it is of course sterile in the gland, no less a number per cubic centimetre than 100 individual bacteria, and that as sold in the ordinary London dairy it contains something like 3 000,000 or 4,000 000 specimens. If at this point the progressive increase be not checked by some form of sterilisation before the milk is finally consumed the number of micro organisms may become almost infinite. This growth of bacteria can only occur at the nutritive expense of the milk itself, a loss which probably far outweighs any possible detriment to the nutritive value from the ordinary process of sterilisation. Bacteria, as we know, are wasteful and extravagant feeders, the chemical energy of which they deprive the nutritive media in which they thrive is utterly disproportionate to the energy which they re-accumulate in their growth.

With regard to the respective nutritive values of boiled and unboiled milk the question is one of many issues. As has been pointed out by one of our correspondents, there is ample experimental evidence to prove that from the point of view of digestibility and absorbability from the bowel neither variety can materially yield in superiority to the other, if anything the balance inclines to the side of boiled milk. Nor is there any reason for supposing that as measured in calories or any other unit representing its energetical equivalent as a food, the nutritive value of milk presents differences either in the boiled or unboiled condition. There is, however, a quality possessed by milk, in common with other animal and vegetable juices, which cannot be measured, as far as we know, by any ordinary unit of energy. This unknown quality has been variously described as the anti scorbutic or vital element of fresh food substances—a *tertium quid* which has so far remained undefined. We know, however, that in some form or other it is an absolutely essential ingredient of food if animal life is to be maintained for any considerable period of time. We gather, also that in the case of milk this unknown element it is at its maximum of efficiency at the moment when the mammary secretion leaves the udder and that from that time forward it suffers a gradual fall in its index of utility, whether it be merely kept for ordinary periods of time or whether it be exposed to mechanical manipulation, to the action of heat or chemical substances, or whether it be simply diluted with water. The exact *modus operandi* of these deleterious processes is still a matter of speculation. It must, however, be borne in mind that milk represents a special form of disintegrated protoplasm, and that as the dying cell gradually breaks down into a solution containing emulsified fat, proteid, sugars, and salts, the complex chemical affinities of a living tissue are loosened or disunited, so that finally a dead, some say a dying, solution of mixed elements is discharged from the lacteal ducts for the purposes of extraneous nutrition. It seems reasonable to suppose that the sum total of these immeasurable energies must ultimately depend on the degree in which the normal chemical complexes composing the original protoplasm are loosened or disunited in the natural evolution of death, or subsequently by mechanical or chemical processes *in vitro*. The further the analytical disintegration is carried the more difficult must be the subsequent synthetical processes by which a substance so disintegrated is made to live again in the tissues of the animal organism which uses it as a source of energy. And, further, it may depend upon the inherent vital powers of the organism whether or no in any particular case such a source of energy can be utilised in any degree whatsoever. As far as fats, sugars, and proteids are concerned, we know that, as they occur in boiled milk they are readily utilised by the animal economy. We do not know, however, to what extent the organism is capable of re uniting other chemical affinities which may have been disunited in the process of boiling. For instance, BUNGE many years ago asked the pertinent question whether it was not possible that the inorganic cells of milk might be combined with some organic substance and that they were only "digestible in that condition." We are still waiting for an authoritative answer, though for practical purposes the question is narrowed down to one of utilisation by the tissues rather than digestibility by the stomach or bowel. One of our correspondents—namely, Dr. R. HUTCHISON—has referred to the great preponderance of phosphates in the "skin" of boiled milk. The very presence of these "dead" phosphates may be a measure of the degree of chemical disunion between these and other salts and their organic bases brought about by the procedure of boiling. If it be true that the living organism stands in constant need of a supply of anti scorbutic energy in its food, and that this element can be variously destroyed by manipulative processes it follows that when milk constitutes an exclusive dietary extreme care should be exercised in its adequate preservation or provision should be made for providing a substitute. *In the case, however, of* adults, when the normal diet is a mixed one containing an abundance of fresh food it is a matter of indifference whether it be present or whether it be absent in the milk which can at most only constitute an insignificant factor in the daily nutritive supply.

It would be presumptuous to suppose that the last word has been spoken in this controversy, but pending more convincing and unequivocal evidence we are of the opinion that the dangers which have been attributed to boiled milk have been exaggerated. Moreover, boiled or sterilised milk in its application to infant feeding—or for the matter of that to adult feeding—has in competent and experienced hands proved a perfectly safe and satisfactory food for all the purposes of nutrition. At all events, we are satisfied that there is clear and conclusive evidence that boiled milk when scientifically administered can supply all the essential elements of a physiological dietary. It has taken many years of patient insistence on the part of medical men, it has taken men of the calibre of TYNDALL, of PASTEUR, and of LISTER to educate the public to a proper sense of the importance of "cleanliness"—that is to say, cleanliness in its bacteriological interpretation—so that for our part we regard it as regrettable that any opportunity should be given to the public to call in question the value of this principle, whether in its general or particular applications. Such an opening for criticism or distrust is not only fraught with danger to the public, but also lends colour to the charge of inconsistency which has ever been the opprobrium of the medical profession.

Annotations.

"Ne quid nimis."

INDECENT ADVERTISEMENTS.

AT Lambeth Police-court recently a man named Wilkins was committed to take his trial at the Old Bailey on a charge of selling indecent photographs which he advertised in the newspapers, describing them, without too closely veiling their nature, as "continental studies from life." Mr. Wontner, who appeared for the police, appealed to the magistrate asking him for an expression of opinion which might act as a deterrent upon the newspapers which published such advertisements, pointing out that without the aid of advertisement the trade in obscenity of this class could hardly exist and certainly could not prosper. He further stated that he would be sorry to mention the names of some of the newspapers in which the advertisements appeared and which he held in his hand because they were so "respectable" We agree with Mr. Wontner that such advertisements are a disgrace to all newspapers in which they appear, although we do not see why in asking for a public rebuke he should have withheld the names of the "respectable" offenders. We have ourselves protested against the advertisement of professed abortifacients until our readers must be almost tired of the subject; we have given the names of the offenders unsparingly; and this, aided by certain recent prosecutions, has practically stamped out this particular style of advertisement, and scotched, though, perhaps, it has not killed, the trade. We have pointed out again and again that newspapers continually insert advertisements which are obscene by Act of Parliament if exhibited on a gate post or in a urinal, and which found in the places named would be the subject of prosecution. But if we have suggested that a newspaper should keep its columns as free from indecency as a public latrine, we do not see that the police have great cause to complain in the matter. In many cases they could prosecute the newspaper. In any case the advertisement affords them the name and address of the vendor of filth—information of which they so rarely avail themselves that his trade practically goes on without check from the appointed administrators of the law. For years the advertising and selling of would-be abortifacients went on without any hindrance from the police. The Chrimes brothers were prosecuted because they took to blackmail and continued until at last one or more of their victims complained. Some time afterwards the firm that traded under the name of Frain was prosecuted, but in our columns we had given the names, the letters, and the analysis of the goods of such persons as Ottey and others at least as bad as "Frain" whose case we had dealt with long before the police took it up. On the whole, we are of the opinion that the disgraceful trades alluded to owe their prosperity quite as much to the laxity of the police as to the venality of the newspapers, which at any rate inform the police as to what is going on in as plain terms as they inform the public

A CONCOCTION.

WE have a bone to pick with *Truth*. While thinking it proper and becoming to afford publicity to an anonymous and malevolent story,[1] in which a soldier is represented as having had his eyes removed one after the other by military medical officers in the vain hope of relieving pain that in reality was due to an alveolar abscess, the editor explicitly disclaims all responsibility for the statements therein. Yet he proceeds to formulate the following conclusion: "I take this to be an argument in favour of 'post-graduate study' for army medicos, whether British or Indian." Post-graduate study is an excellent thing in every profession, but to find an argument in its favour in what is evidently a cock-and-bull invention is distinctly illogical. *Truth* has rendered so many services to the public and so evidently intends to be fair in the many-sided criticisms which its readers expect that we are disappointed to find in its columns the passage to which we have alluded. Such a story, reflecting so terribly on the scientific position of the Royal Army Medical Corps, should not, we think, have been published until its accuracy was demonstrated beyond contradiction, and even then there are circumstances which might well have determined its suppression. It is, of course, a manifest concoction.

FRUIT IN THE ASSUAGEMENT OF THIRST.

CHEMICAL analysis would assign practically no nutritive value to the juicy fruits, for they consist of little more than a cellulose envelope containing a solution of sugar, the amount varying from 17 per cent., as with grapes, to about 1·4 per cent., as with lemons. The amount of water in fruit is considerable. In water-melons it is no less than 95 per cent., in grapes 80 per cent., in oranges 86 per cent., in lemons 90 per cent., in peaches 88 per cent., in apples 82 per cent., in pears 84 per cent., in plums 80 per cent., in nectarines 83 per cent, and in strawberries 90 per cent., not a fruit in the whole category containing less than 80 per cent. The irresistible conclusion, considering these facts, is that fruit plays an important rôle in diet as a thirst quencher. Certainly when fruits are freely represented in the diet less fluid requires to be consumed and fruits would appear to be endowed with a subtle inimitable flavour which is ample inducement to imbibe fluid in this most wholesome form. The question so prominent in people's thoughts at this hot season of the year as to what to drink might, therefore, on sound physiological reasoning, be answered, eat sound, ripe, juicy fruit. It is noticeable that as fruit enters into the diet the indulgence in alcoholic drinks is diminished. Thus it is most satisfactory to observe people taking a good juicy slice of melon as preparatory to a meal instead of sherry and bitters or a "cocktail." This is a most commendable practice and the proceeding is dietetically speaking perfectly rational. The flavourings of fruits, although of little nutritive value, are undoubted stimulants to the appetite and aids to digestion. Moreover, the juice of fresh cut fruit is perfectly free from microbes, is as sterile as freshly clean-drawn milk, and the fruit acids tend to inhibit the power of those disease-producing bacteria which flourish in neutral or alkaline media. The marked anti-scorbutic properties of fresh fruit due to the vegetable acids and their salts in the juice are of great importance. For the most part these acids are combined with potash and hence a free diet of fruit preserves a healthy alkaline condition of the blood and there is consequently a reduced tendency to the depositing of acids in the tissues. Peaches and that delicious and delicately flavoured fruit the nectarine contain quite a small quantity of sugar and this, coupled with the fact of the tenderness of their pulp, makes them suitable for the gouty and diabetic. There can be no doubt that the juice of sound ripe fruit is an ideal means of assuaging the intense thirst of hot weather—cooling, refreshing, and of an agreeable flavour. It is a common experience that the more a person drinks to satisfy the demands of thirst in hot weather the worse he feels. The temptation is to gulp down huge quantities of fluid with the result that excessive perspiration sets in and a very uncomfortable and unrelieved feeling follows. On the other hand, a judicious amount of sound, ripe, juicy fruit, whilst containing all the water necessary to assuage thirst, would lead to no such distress and would exercise other healthy effects on the bodily functions.

THE RELATION OF BODILY MUTILATIONS TO LONGEVITY.

IN the *Boston Medical and Surgical Journal* of August 8th Dr. John Homans of Boston has an interesting article upon the subject of the Relation of Bodily Mutilations to Longevity. Dr. Homans is the medical director of the New England Mutual Insurance Life Company and so he writes from one point of view as an expert. But, so he says, there is but little known about the subject and, so far as he knows, there are no statistics on the matter. The only figures which are illustrative are those concerned with men who lost their limbs in the Civil War and who afterwards applied for the Government artificial limbs. In general, says Dr. Homans, the deprivation of any part of the body would make a man's chance of longevity less than that of sound, unmutilated persons, but in many instances there are ameliorating circumstances which would render such mutilated persons as good lives as most other people of the same age. Loss of the upper extremity increases in importance as regards longevity the nearer that the amputation has been made to the thorax. There is also a certain amount of mental depression attaching to the loss of the whole or part of a limb. Dr. Homans points out that the loss of an arm might affect the respiratory power of the thorax in certain positions, and naturally the loss of both arms would be even more injurious. The late Dr. W. Brinton, who in 1856 gave some lectures at the Royal Free Hospital on "Examinations for Life Insurance," remarked that "amputation of a limb for disease is said to confer an increased risk of visceral—especially of pulmonary—disease." In our own opinion the loss of a limb would increase risks to life from injury. Obviously, a man with only one leg is more likely to fall than a man with two, and a man with only one arm would not be so likely to save himself if he did fall as a man with his full complement of limbs. Dr. Homans gives some figures showing that the death-rate among soldiers who had served in the American Civil War and who had lost a limb or limbs was very high, but, as he says, these statistics are not altogether trustworthy, for many men who had lost a limb had also sustained other injuries. Some five years after the war the Government of the United States offered an artificial limb, or its commuted value once every five years, to all soldiers who had lost a limb in the war. At the close of the war there were 13,052 recoveries from amputations such as would have entitled the sufferers to apply for an artificial limb. In 1870, when the Act of Congress came into operation, only 10,187 applied, so that presumably 2865 maimed soldiers had died, being very nearly 22 per cent. of the total. From the close of the war up to 1890 5621 soldiers died out of the original 13,052, or 431 per 1000. In the first five years the percentage was, as we have said, nearly 22. In the last it was only 7 58 of those alive in 1885. As regards abdominal sections, Dr. Homans says that they all increase risk to life, principally on account of the chance of ventral hernia at one time or another setting in, but removal of small portions of the bowels is, he thinks, not likely to shorten life. Dr. Homans has raised a very interesting point and one which might be further studied with advantage.

THE NEW CHIEF MEDICAL OFFICER FOR CAPE COLONY.

WE have had sent to us from Cape Town copies of a newspaper published in the colony and called *Greater Britain*, in which letters are appearing commenting seriously upon the appointment of Dr Gregory to the post of principal medical officer of the colony. We have been asked to express an opinion upon the appointment, which, we are informed, has not been favourably received by the medical profession; indeed, from the letters published by our contemporary, the medical profession do not consider that Dr. Gregory has any proper claims to the post. We are not in a position to say much upon the matter. Probably those who appointed Dr. Gregory had good reasons for thinking that he was a fit man to fill a difficult and responsible position, for we cannot imagine a more serious offence to the community than the appointment as guardian of its public health of a gentleman of inadequate qualifications. Dr. Gregory seems to have spent the greater part of his time in the colony not so much in acquiring a knowledge of sanitary matters and administrative experience in the details of public health as in one of the departments of Cape Town Colonial Office. In the current issue of the Medical Directory we are unable to find his name, but in the South African Medical Directory of 1896 there is a Dr. Gregory residing in the colony, but he is not given as a D.P.H. The public health of Cape Colony at the present moment is of paramount, even imperial, importance; and we certainly think that no one should be appointed to the position who is not *hall-marked as an expert in sanitary science. Dr. Gregory* may be this, for all we know. We are not reflecting upon him, but stating a truism.

OZONE IN THE RAILWAY CARRIAGE.

THE air of a railway carriage is seldom without an objectionable characteristic; indeed, it has a peculiar smell of its own. The atmosphere may be tainted by the much-used upholstery or by varnish or oil, or the grime deposited by the engine on the seats and hat rails and in the various crevices, of which plenty are usually available for the process. Of course the windows may be flung wide open to get as much change of air as possible, but then dust, smut, and draughts invade the compartment. It is, in fact, difficult to keep the air of a railway carriage in a satisfactory state, and how bad it gets sometimes may easily be ascertained by entering a crowded compartment at the end of a journey. Railway headache is without doubt largely to be attributed to the impure and re-breathed air of the carriage. Many contrivances exist for the ventilation of railway carriages, but the majority of them act with limited success. Nothing sweetens or freshens stale air better than ozone and now that most of the railway companies have successfully adopted a system by which each carriage on its journey develops by means of a dynamo attached to the axle-trees its own current of electricity for lighting purposes there is no reason why the same current should not be utilised at the same time to ozonise the air of the compartment. The quantity of ozone required is small. The result would certainly be good since ozone has a remarkably destructive action on aerial impurities and unpleasant smells, and gives the air a degree of freshness similar to that of the sea-breeze. It rapidly overcomes the smell of stale tobacco-smoke which so persistently lingers in smoking compartments or in rooms where the upholstery is heavy or where cumbersome curtain hangings are the custom. It is reasonable to believe that if this expedient could be adopted much of the distress and fatigue of a railway journey would disappear. It is too much to hope that the same means of maintaining air in a fresh and pure state could be adopted in omnibuses, for even the problem of satisfactorily lighting these vehicles has not yet been solved. Again, the speed of the omnibus, we imagine, would never be high enough to generate a current sufficient for lighting purposes. The Underground Railway or "The Tube" might adopt automatic ozonisers in their trains with advantage; the suggestion might even appeal to the directors and shareholders of the former company as an alternate scheme to electric traction.

CERVICAL AND BULBAR TABES.

Dr. S. Solis Cohen and Dr. W. G. Spiller of Philadelphia report, in the August number of the *American Journal of the Medical Sciences*, a rare and interesting case of tabes affecting the cervical and bulbar regions of the spinal cord, together with the results of necropsy. The condition is one which has been mistaken for, or wrongly diagnosed as, syringomyelia. The patient was a man, aged 67 years at the date of his death in 1900. At the age of 25 years he contracted syphilis. He had had secondary, but not tertiary, syphilis. Later he developed ptosis of the right eye, inequality of the pupils, difficulty in coördinate movements of the lips, so that whistling and smoking were difficult, and the latter habit had to be abandoned. Deglutition was also attended with considerable difficulty. The tongue exhibited fibrillary tremors and some hemiatrophy of its left side. The tactile sense was fair, but the temperature sense was markedly impaired on the right side of the face. Vision was good and ophthalmoscopic examination showed normal discs. He now developed an irritable ulcer of the cornea which under treatment healed in about 10 days. The pupils showed the Argyll-Robertson symptom. The knee-jerks were present and the mental condition was clear. Gait was normal and he could stand steadily with his eyes closed or balance himself on one foot at a time. The above clinical report was made in 1889. He remained under treatment for nearly 12 years afterwards, dying in 1900 from pulmonary œdema [and inanition following complete paralysis of deglutition. At this time the sense of taste had been largely lost for some time, and he had also begun to complain greatly of pain in the abdomen which was very tender to touch. Occasional but severe darting pains were experienced in the right leg and were relieved by morphine. The mental condition was clear to the last. He never at any period of the illness had ataxia or abasia. He had had two attacks of uræmia, one about two years before death and one about 10 days before the same. At the necropsy the following changes were found. The whole of the Rolandic gyri and convolutions were somewhat atrophied and depressed, the sulci thus appearing wide and gaping. This atrophy involved also the whole of the pre-frontal operculum. There was also a localised atrophy of the fore part of the superior frontal convolution on the right side, and the occipital cornu of the lateral ventricle was dilated on the left side to twice the size of its fellow. Examination of the spinal cord showed an absence of degenerated fibres in the lumbar region. In the mid-thoracic region there was very slight degeneration of the posterior spinal roots increasing as the sections passed upwards to the cervical region. At the eighth cervical segment of the cord a narrow band of degeneration began to make its appearance in Burdach's column close to the entry of the posterior roots. This was continued up the cervical region and almost entirely on the right side. With Marchi's method no recently degenerated fibres could be traced in the cord. The anterior cornual cells showed marked pigmentary degeneration. The hypoglossal nucleus was somewhat atrophied on the left side. The ependyma of the floor of the fourth ventricle was granular. The trigeminal nucleus in both its sensory and motor portions was present only on one side, having become entirely degenerated on the other side. The right cerebral peduncle was considerably atrophied. There were atrophy and changes in the oculo-motor nuclei resembling those following section of the nerves. These lesions justified the diagnosis of an atypical and rare form of tabes (cervical tabes), having been noticed but once in 106 cases of tabes studied by Déjerine at the Bicêtre. The present case showed the presence, also, of bulbar tabes, a still rarer condition, of which only three other cases are known to medical literature.

"THE NEW POOR-LAW INFIRMARY AT HALIFAX."

In our issue of last week (p. 462) we commented upon the position at Halifax with reference to the appointment of a medical officer for the new workhouse infirmary. Dr. T. M. Dolan, having refused to take the post without any addition to his present salary, the Infirmary Committee on August 12th offered the post to Dr. J. F. Hodgson. We understand that the reason for the cheeseparing policy of the guardians was that if Dr. Dolan had been granted £105 in addition to his present salary it would have entailed an addition to his superannuation allowance of £80. Notice was given that at a meeting of the guardians held on August 14th a motion was to be brought forward which if carried would do away with the difficulty so far as regarded the superannuation question, but at the time of going to press we have no information as to the result of the meeting in question.

STREET NOISES.

We have received sundry letters from various correspondents upon the intolerable nuisance caused by sellers of newspapers and others. One correspondent ends up his letter by saying, "Surely there is some remedy." The only remedy is as follows. Next time he is annoyed by a newspaper seller yelling he must go out, he must keep the newspaper seller in view with one eye and with the other look for a policeman. When he is lucky enough to see both—the policeman and the yeller—he must complain to the policeman who will ask the yeller for his name and address. Some name and address will be given, and at some future date the complainant will receive a summons to attend the police-court of his district. There he may or may not find the yeller. If by great good luck he does find him the man or boy in question possibly will be fined and the nuisance will go on in exactly the same way as before. This is the only remedy of which we know, and if it resembles the celebrated recipe for killing fleas we must remember that we live in a free country. There are numerous sellers of newspapers who do not yell, but that is not to the point. Why deprive a small boy or a large man of the pleasure of roaring "Three o'clock winner"? True, he annoys a great many hard-working ratepayers, but that only makes his employment more enjoyable. The magistrates are the persons who are to blame. First of all because they will not, with possibly the exception of Mr. Plowden, hear any charge except one made on the authority of a dweller in the district, and secondly because they inflict such ridiculous penalties But why London, which suffers enough from unavoidable noises, should be compelled to endure absolutely unnecessary noises is one of those problems which are as incapable of solution as the idiotic regulations of the Post Office as regards what constitutes one word or two in a telegram We can only advise everybody who suffers from street noises to worry his Member of Parliament, his borough council, and his London County Councilman until something is done

A UNIFORM METHOD FOR THE ESTIMATION OF ARSENIC.

THE apparent ubiquity of arsenic has rendered an accurate method for its estimation even in the minutest amounts very desirable The discordant views expressed by chemists as to the trustworthiness of methods which have hitherto been looked upon as exact and unfailing have done much to complicate the question Careful investigation, therefore, of all the methods known both for the detection and estimation of arsenic was needed and such an inquiry has been approached in an eminently practical way by a joint committee of the Society of Chemical Industry and of the Society of Public Analysts This committee have circulated amongst the members of the two societies a number of samples containing definite quantities of arsenic and have carefully considered the results which have since been returned *We note with satisfaction that they already* report that the results will probably justify them in prescribing a method for dealing with the various substances, but before taking this step they think it advisable to submit this method to continued practical trial. We hope that in this way a standard method will be reached, and further, that some light may at the same time be thrown upon the organic compounds of arsenic, with the view that the arsenic in these compounds may be made to respond to the same tests and to admit of the same method of estimation The cacodyl compounds, which may be taken as leading types of organic arsenic bodies, differ vastly clinically from the inorganic compounds, and a similar difference exists in regard to the chemistry of the arsenic in this particular state of combination The results of this *very sensible inquiry will be of the utmost* importance, and they should be of eminent service to the members of the Royal Commission on Arsenic, who still have a colossal field of inquiry before them which must be thoroughly gone over if the final issue is to be satisfactory

A CASE OF BURROWING EPITHELIOMA OF THE ALVEOLAR PROCESS.

IN the current issue of the Transactions of the Odontological Society an account of an interesting case of burrowing epithelioma of the jaws is given by Mr Stanley Colyer For two years previously to being seen the patient, a female, had suffered from a sinus over the region of the left maxillary lateral incisor which was pulpless Necrosis of the cementum was diagnosed and the root was extracted There were no swelling of the alveolus and nothing in any way to suggest malignant disease An examination of the root showed that the cementum covering the lower third was necrosed, while immediately below the necrosed portion and attached to the pericementum, which appeared otherwise quite healthy, were some small lumps of ragged tissue which had obviously been torn away from similar tissue in the alveolus. *The specimen was placed in formalin* with the intention of making a microscopical examination. Three weeks later the patient returned with acute pericementitis extending from the right central incisor to the left second premolar The sinus had not healed and a suspicion of malignant disease was aroused. A microscopical examination of the tooth which had been extracted was made and epithelioma was diagnosed. The growth on removal was found to extend from the right cental incisor to the left first molar, the antrum not being in any way invaded The interesting features of the case were. (1) the absence of external signs of the disease; (2) the escape of the antrum from implication, even though the growth in the alveolar portion of the bone was extensive, and (3) the origin of the growth, the epithelioma apparently having arisen from the tissue of the pericementum and not the oral epithelium An endeavour was made by Mr Colyer to substantiate the last-named feature, and it was shown that many observers had demonstrated the presence of isolated pieces of epithelium—remnants probably of the epithelial sheath of Hertwig—in the pericementum These remnants were, he thought, an example of Cohnheim's "rests" and could, under suitable circumstances, become the forerunners of malignant disease

THE SURGICAL TREATMENT OF ACUTE NEPHRITIS

IN the last few years the question of the surgical treatment of acute nephritis has from time to time been brought forward, and it formed the subject of a discussion at the late meeting of the British Medical Association It is again to be considered at the approaching meeting of the Scandinavian Medical Congress which is to be commenced on August 29th in Copenhagen Professor K G Lennander of Upsala University will contribute a paper on this subject *to open a discussion While refraining from undue expectations* of the benefit to be derived from the recent surgical departure, we are justified in hoping for some improvement in the treatment of a very refractory condition

POPULAR MEDICINE.

OUR contemporary the *Globe* on August 14th published a "turnover," entitled "*Curious Cures*" *The writer, after* quoting the example of the sea captain who, not being able to supply the medicine numbered 15 in his book of directions, proceeded to give his patient Nos 7 and 8 mixed, goes on to give examples of various popular superstitions in medicine The singularly nasty concoctions which our ancestors prescribed for all and sundry were mostly derived from animals, and later researches have shown the belief in them to possess—in some instances, at least—a modicum of foundation Thus a toad boiled in wine gave a very strong poison which if administered to a dropsical person would probably kill him, but which sometimes effected a cure It has been shown, however, by sundry observers that the skin of the toad secretes a substance having an action closely allied to that of digitalin and so it might be of great use in cases of *cardiac dropsy To anyone, however, who is* inclined to pursue this subject further we recommend a perusal of the work of that ingenious gentleman the Reverend Edward Topsell, who was vicar of East Heathly and who died about 1638 His "History of Four Footed Beasts and Serpents" will be found a mine of information To the edition of 1658 is appended "The Theater of Insects, by Tho Mouffet, Doctor in Physick." This work is also full of remedies For instance, says the learned Doctor "That knotty Whip of God, and mock of all Physitians the *Gout*, which learned men say can be cured by no remedy, finds help and cure by a Spider layd on, if it be taken at that time when neither Sun nor Moon shine, and the hinder legs pulled off, and put into a Deers skin and bound to the painful foot and be *left on it for some time*" Dr Mouffet relates a story of a quack who cured a lady of a tympany by giving her a spider to swallow and concludes his essay with the following eminently sound remarks which are as suitable now as they were when originally written: "Truly in this present corruption of manners and times, how highly is such a Mountebank esteemed, wherein chance is accounted for skill, and one accidental rash cure of a disease, with danger ofttimes of the patient's life, makes a Quacksalver a great Physician, and he is judged worthy of praise and honour? But a better revenging Judge will correct these things; we pass on to Pismires."

THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of Hong-Kong received at the Colonial Office on August 19th states that for the week ending August 17th there had occurred 4 fresh cases of bubonic plague, together with 5 deaths. For the week ending August 11th 8 cases of plague and 3 deaths from the disease, all among natives, have been reported from all Egypt. Six cases and 1 death were reported from Port Said, 1 case and 1 death from Zagazig, and 1 death out of hospital at Alexandria.

MEDICAL OFFICERS IN THE HIGHLANDS AND ISLANDS.

THE *Orkney Herald* of August 1st contains the following advertisement:—

WANTED.—A LADY MEDICAL OFFICER for PAPA WESTRAY, to enter on duties 3rd October. Salary £55 with fees. Apply to John Hourston, Inspector of Poor.

Papa Westray is, as its name shows, one of the lonely little islands like Papa Strona and Papa Stronsay, which were occupied by Celtic missionaries, probably from Ireland, in the sixth century. The island in question lies off the larger island of Westray, from which it is separated by about three miles of sea. It is three and a half miles long by about three-quarters of a mile wide, and its population, according to the *Times Gazetteer* for 1899, is 377. The people are mostly of the poorer class and the medical officer cannot expect to make more than from £3 to £5 in addition to the official salary. This latter, though small, is generous as compared with those offered by a Shetland parish council, namely, £25 for Whalsay and the Skerries, and £15 for Nesting.[1] The Scottish medical officer, it must be remembered, has no security of tenure. He is liable to be dismissed at any moment by the parish council and no appeal lies to the Scottish Local Government Board. We have no desire to prevent the inhabitants of Papa Westray from being able to obtain medical aid if they need it, but we earnestly implore all candidates to make certain that if elected they will obtain three things—namely, fixity of tenure, a free annual holiday, and an adequate salary. The life would be very lonely, the winter is very long and the days are very short—although as against this may be set the fact that there is no night in the summer, or practically none; but it would require the zeal and energy of a Columba or of a Cormac for an educated man or woman who had not been brought up to agricultural pursuits or a sea-faring life to be able to occupy the many hours which necessarily must be passed in exercises outside purely professional employments. Lord Balfour is recommended to consider the need for further legislation.

TREATMENT OF TUBERCULOSIS BY GOAT'S SERUM.

WE have received a pamphlet entitled "Remarks on Tuberculosis and its Treatment," by Dr. Baradat of Cannes, which contains observations made by him at the recent Congress on Tuberculosis. He draws attention to the generally accepted theory that there are two factors in the etiology of tuberculosis, the infectious agent and the soil on which it develops, the characteristics of which are either acquired or hereditary, and insists that for the purposes of treatment the one is as important as the other, and after a survey of various forms of treatment proceeds to give his own experience on the use of serum therapy founded on the supposition that the blood of certain animals confers on other animals immunity from tuberculosis and may even cure this disease. His view, however, is not only that the serum of goat's blood is antitoxic and bactericidal, but also that it is a "tonic"—that is to say, stimulating and regenerative. He quotes Landouzy who maintains that it is this idea of helping those who are in the incipient stage, at a time when the germs of secondary infection have not yet attacked them, that has led medical men to make use of "the immunising agents that are antitoxic or bactericidal owing to their strengthening action on phagocytosis." Dr. Baradat also refers to the theory of Metchnikoff who regards the sera not as antitoxic but as stimulating agents of phagocytosis, or, in other words, provokers of organic resistance. The use of the serum of the goat has been used in cases of tuberculosis by various observers with varying success, but has not been largely employed in this country. Dr. Baradat maintains that the use of the serum has given him "unexpected results" in serious cases of tuberculosis. We infer from the context that he means successful results. He administers one hypodermic injection of two cubic centimetres of the serum every other day. In some cases, however, in the case of nervous patients especially, he has observed after each injection an exaggeration of cellular activity, showing itself in the shape of fever, erythema, and dyspnœa; in such cases Dr. Baradat administers the serum internally, but in order to obtain the same tonic and stimulating effects the dose must be increased from two to 10 cubic centimetres. There is nothing more deceptive than to draw conclusions from the result of treating a few cases of pulmonary tuberculosis with a certain remedy, but Dr. Baradat's experiences would indicate that the administration of the serum of goat's blood should have further trials in the treatment of patients suffering from tuberculosis.

WE deeply regret to announce the death of Lady Simon, the wife of Sir John Simon, and tender our sincere and respectful sympathies to her husband. Lady Simon, who had attained the great age of 84 years, had been the dearly loved wife of her distinguished husband for 53 years.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6727 births and 4673 deaths were registered during the week ending August 17th. The annual rate of mortality in these towns, which had been 21·2, 22·4, and 22·1 per 1000 in the three preceding weeks, decreased last week to 21·3. In London the death-rate was 19 6 per 1000, while it averaged 22·4 per 1000 in the 32 large provincial towns. The lowest death-rates in these towns were 10·4 in Halifax, 13·2 in Croydon, 13·9 in Cardiff, and 14·2 in Brighton; the highest rates were 27·2 in Hull and in Sheffield, 28·7 in Salford, 30·2 in Gateshead and in Sunderland, and 30·5 in Birkenhead. The 4673 deaths in these towns last week included 1620 which were referred to the principal zymotic diseases, against 1755 and 1752 in the two preceding weeks; of these 1310 resulted from diarrhœal diseases, 97 from measles, 65 from whooping-cough, 64 from diphtheria, 42 from scarlet fever, 40 from "fever" (principally enteric), and two from small-pox. The lowest death-rates from these diseases were recorded in Plymouth, Bristol, Swansea, and Halifax; and the highest rates in West Ham, Salford, Hull, Sunderland, and Gateshead. The greatest mortality from measles occurred in West Ham, Salford, and Sheffield; from scarlet fever in Preston; from whooping-cough in West Ham and Swansea; and from diarrhœal diseases in Manchester, Salford, Burnley, Hull, Sunderland, and Gateshead. The mortality from "fever" showed no marked excess in any of the large towns. The 64 deaths from diphtheria included 30 in London, six in Leeds, five in Leicester, three in West Ham, and three in Sheffield. Two fatal cases of small-pox were registered in London, but not one in any other of the 33 large towns; the number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 11, 13, and 11 at the end of the three preceding weeks, had risen again to 13 on Saturday, August 17th; eight new cases were admitted during the week, against two,

---

[1] THE LANCET, Dec. 1st, 1900, p. 1695.

four, and three in the three preceding weeks The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 3101, against numbers increasing from 2907 to 3148 on the four preceding Saturdays, 300 new cases were admitted during the week, against 374, 391, and 306 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 134, 126 and 126 i [illegible] ied last week to 103, and [illegible] The causes of 35, or 0 [illegible] 33 towns last week were not certified, either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Bristol, Manchester, Salford, Bradford, and in 14 other smaller towns, the largest proportions of uncertified deaths were registered in Birmingham, Liverpool Preston, and Sunderland.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 19 8 and 19 2 per 1000 in the two preceding weeks, further declined to 19 0 per 1000 during the week ending August 17th, and was 2 3 per 1000 less than the mean rate during the same period in the 33 large English towns The rates in the eight Scotch towns ranged from 12·7 in Leith and 14·2 in Perth to 19·6 in Paisley and 20 8 in Glasgow The 606 deaths in these towns included 111 from diarrhœa, 18 from whooping cough, 11 from measles, five from "fever," three from scarlet fever, and two from diphtheria. In all 150 deaths were referred to these principal zymotic diseases last week, against 134, 174, and 168 in the three preceding weeks These 150 deaths were equal to an annual rate of 4 7 per 1000, which was 2·7 per 1000 below the zymotic death rate during the same period in the 33 large English towns The fatal cases *of diarrhœa, which had been 99 128, and 129 in the three* preceding weeks [illegible] 111, of which 68 occurred in [illegible] Edinburgh, 10 in Leith, [illegible] Aberdeen, three in Paisley, and three in Perth The deaths from whooping cough, which had been 28 and 12 in the two preceding weeks, rose again to 18 last week, and included 10 in Glasgow four in Edinburgh, two in Dundee and two in Paisley The fatal cases of measles, which had been 13 in each of the two preceding weeks, declined last week to 11 and were all registered in Glasgow The deaths referred to different forms of "fever," which had been two and six in the two preceding weeks, declined to five last week, and included two in Glasgow and two in Paisley The [illegible] two of which were recorded [illegible] the number in the preceding [illegible] to diseases of the respiratory organs in these towns, which had been 65 and 44 in the two preceding weeks increased again last week to 53, but were slightly below the number in the corresponding period of last year The causes of 14, or more than 2 per cent, of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 20·6 20 6, and 22·4 per 1000 in the three preceding weeks, declined again to 19 9 per 1000 during the week ending August 17th During the past four weeks the death rate has averaged 20·9 per 1000, the rates during the same period being 19 2 in London and 17 6 in Edinburgh The 143 deaths of persons belonging to Dublin registered during the week under notice were 18 below the number in the preceding week, and included 34 which were referred to the principal zymotic diseases, against 26 32, and 34 in the three preceding weeks, of these 30 resulted from diarrhœa, three from whooping cough and one from scarlet fever These 34 deaths were equal to an annual rate of 4 7 per 1000, the zymotic rates during the same period being 6 0 in London and 2 8 in Edinburgh The fatal cases of measles, which had been 14 20, 23 and 33 in the four preceding weeks, declined again last week to 30 The 143 deaths in Dublin last week included 39 of children under one year of age and 33 of persons aged upwards of 60 years; the deaths of infants showed a very marked decline, but those of elderly persons were slightly in excess of the number recorded in the preceding week. Five inquest cases and three deaths from violence were registered, and 41, or nearly one-third, of the deaths occurred in public institutions. The causes of 10, or nearly 7 per cent, of the deaths in Dublin last week were not certified.

THE SERVICES

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified —Fleet Surgeons George S Smith to the *Cæsar* and Alexander M French to the *Empress of India* Staff Surgeons Frederick W Stericker to the *Fox* and J A Moon to the *Implacable* Surgeons J H Read to the *Implacable*, Henry F Raper to the *Vulcan*, Robert W G Stewart to the *Hazard*, Robert R. Fasson to the *Cæsar*, John E H Phillips to the *Empress of India*, and A B Shaw P T Nicholls A J Gailton and G S Davidge to the *Duke of Wellington* additional for Haslar Hospital

ROYAL ARMY MEDICAL CORPS

Major G Tuke joins at Woolwich, and Lieutenant Davies and Lieutenant A W Gibson are posted to the Cambridge Hospital, Aldershot, for duty Major Dodd assumes temporary charge of the Connaught Hospital at Aldershot

MENTIONED IN DESPATCHES

In despatches from Lord Kitchener published in the *London Gazette* of August 20th 1901 and dated Pretoria July 8th 1901, the following officers are mentioned Surgeon Captain I B *Reid West Australian Mounted Infantry, showed an* absolute disregard of danger in performing his duties at Brakpan on May 16th Captain J G Berne, R A M C, for special good service during the Boer attack on convoy near Mooifontein south of Bethel May 25th, 1901 (Private Dawes, R.A.M C, is also specially mentioned for good work under heavy fire on the same occasion) Surgeon Captain E J O Neil, New Zealand Mounted Rifles, who, on June 16th, under heavy fire, went three times to the wounded and succeeded in getting in Lieutenant Ryan and two men

SOUTH AFRICAN WAR NOTES.

The following have been discharged from hospital to duty —Captain H W Vaughan Williams R.A M C, Lieutenant P G Stock R A M C, and Civil Surgeons Runciman and James McMurray

Civil Surgeon H M. Apthorp is on passage home

INDIAN MEDICAL SERVICE.

The following is the list of successful candidates for the Indian Medical Service at the examination held in London on Feb 9th and following days —

Names	Marks	Names	Marks
A J J Lister	3245	R J Bradley	[illegible]
T F B Williams	3156	I A Loch	[illegible]
S H L Abbott	3077	R M Carter	[illegible]
A W Greig	3015	R I Hagger	[illegible]
R I Lloyd	3013	D O P S Baker	[illegible]
J Woods	2965	T W Harley	[illegible]
H B Steen	2940	J W McCoy	[illegible]
D Munro	2929	R A Willcocks	[illegible]
I Bisset	2910	T G I Paterson	[illegible]
J J Clements	[illegible]	D G Rai	[illegible]
A W Overbeck Wright	2675		

NAVAL AND MILITARY PRISONERS IN IRELAND

A recent blue book dealing with the prisoners of Ireland shows that there has been a considerable increase in the number of naval and military prisoners committed to civil prisons during the past year For the three years prior to 1899 the average number of committals was 290, but in 1899 the numbers rose to 359 and in 1900 to 838. This increase appears to be owing to the large number of troops under arms to the fact that they were to a great extent composed of militia and reservists of different descriptions, and to the great number of fraudulent enlistments, false answers on attestation and serious military crimes committed to obtain discharge The increase in naval prisoners has been principally in Cork and is attributed to the fact that naval manœuvres on a more extensive scale than in the preceding year were carried out off the southern coast of Ireland in 1900 All defaulters sentenced to imprisonment during that time were sent to Cork Prison The committals last year from Berehaven alone, which is becoming an important naval station were 78 as compared with none in 1890

Surgeon General W Taylor, A M S, C B Principal Medical Officer in India has been appointed an Honorary Physician to the King vice Deputy Inspector General R. Domenichetti, deceased.

DEATHS IN THE SERVICES

Brigade Surgeon Thomas Young Baker, A M S (retired), on August 21st He entered the service in 18[illegible]0 and retired with the rank of Hon. Brigade Surgeon in 1885.

THE
BRITISH MEDICAL ASSOCIATION.
MEETING AT CHELTENHAM.

THE SECTIONS.
MEDICINE.
FRIDAY, AUGUST 2ND.

THE closing meeting of the section commenced with the reading of a paper by Dr. **EDOUARD RIST** (Paris) on

The Bacteriology of Fœtid and Gangrenous Suppuration.

He said that in diseases where fœtor was present, such as appendicitis, mastoiditis accompanied by crackling œdema, and in some cases of empyema, if the pus was examined under the microscope very many bacillary forms could easily be made out. The polymorphism of this assemblage of micro-organisms was very marked, yet after preparing culture-tubes from the same pus, though a luxuriant growth would occur, yet on microscopical examination only a few common forms of bacteria would generally be found. It was not likely that these common forms were the active agents in producing fœtid inflammation, gaseous phlegmon, or discrete gangrene in the lungs. It had occurred to Dr. Rist that the reason why the rarer forms of bacillus would not grow was that the conditions of culture did not suit them. Dr. Veillon of Paris had devised a simple method of anaerobic culture free from the difficulties of the hydrogen and other methods. Diluted pus was mixed with liquid sugared agar and with this tubes were filled to a height of about four and a half inches. The agar was then solidified by placing the tubes in cold water. Under these circumstances all the microbes except those occupying the upper superficial layer of the culture medium were growing under anaerobic conditions. A profuse growth generally occurred and on examining specimens taken from the lower layers of the tube very many organisms were found to be growing, and Dr. Rist gave a long list of names of the bacilli which had been isolated and described by himself and his colleagues, some being new to science. He hoped that in other hands the method might lead to the further elucidation of the nature of the so-called anaerobic bacilli.

Dr. H. J. **CAMPBELL** (Bradford) asked if the pneumococcus of Fraenkel could cause suppuration, as he thought it had done so in one of his own cases.

Dr. **RIST**, in reply, said that it could do so, but that in his opinion, if fœtor were well marked, they ought to be able to find the anaerobic organisms he had been describing, which he considered were the true cause of such conditions and not the bacillus coli communis.

Dr. **MCPHEDRAN** (Toronto) and Dr. **WILLIAM GOLDER** communicated a paper on

A Case of Indigouria.

The condition was merely a clinical curiosity. A male patient, aged 24 years, consulted him for general malaise and tired feelings. No objective signs were discovered, but he mentioned that his urine was of a blue colour. On a specimen being passed it had the characteristic bluish-green colour of indigo. Its specific gravity was 1029. It contained no albumin or sugar. On microscopical examination the pigment could be seen in small blue granules. Dr. McPhedran made some remarks on previously published cases and said that the cause of the condition was quite unknown.

Dr. J. **RIVIÈRE** (Paris) read a paper on

The Abortive and Curative Treatment of Acute Alimentary Diseases, and particularly Enteric Fever and Appendicitis, by a Judicious Use of Calomel, Water, Heat, and Quinine.

The motto of the paper was, "As the microbe so is man killed by his own toxins and refuse." Starting from this thesis Dr. Rivière contended that the best way to treat diseases such as those mentioned, which interfered with the proper excretion of refuse matters, was to administer such a drug as calomel. His practice was to give five grains each of calomel and sodium bicarbonate placed directly on the tongue at midnight, followed next morning by castor oil beaten up with hot water or eight grammes of magnesia. Such treatment seldom failed to reduce fever and he thought that in many cases the reduction was permanent and the treatment harmless. In addition to its use as a cholagogue and intestinal antiseptic calomel was the most powerful and harmless of diuretics. As adjuvants to the calomel treatment he employed hot water and quinine when defervescence had taken place. After describing his treatment of cholera infantum and post-partum inflammation by the same means Dr. Rivière concluded: "All diseases can be referred to one cause—intoxication, and, above all, autointoxication, which in my opinion depends directly on the disturbance and deficiency of the hepatic function. The microbe only enters the lists when the machine is foul and choked because it has not been washed out in time."

The **PRESIDENT** (Dr. E. T. **WILSON**, Cheltenham) and others discussed the paper.

Mr. **CHISHOLM WILLIAMS** (London) read a paper on

The Treatment of Phthisis by Means of Electrical Currents of High Frequency and Potential.

Treatment by these means had given such striking results in his hands that he wished to summarise his results in 43 cases. These were all of over a year's duration. The difference between the currents obtained by an ordinary Ruhmkorff coil and that of Tesla was that in the latter the alternations were infinite and the electro-motor force was proportionally high. Thus in the former they might have alternations of 200 per second and electro-motor forces from 10,000 to 20,000 volts, while in the latter alternations of 1,000,000 per second and the electro-motor force from 100,000 to 1,000,000 volts. In using these he found general electrification better than local and a combination better still. Under this treatment the temperature first rose and then fell and progress could be gauged by noting if the reactionary rise could any longer be induced. If it could not be induced by even prolonged exposure to the currents the patient might be considered well. Cough was relieved, sputum was lessened, and bacilli were reduced in numbers and dwarfed in shape. He did not think they were killed by the current. Sweating subsided and the body-weight increased. Mr. Williams quoted Osler as saying that 95 per cent. of patients were unable to afford any treatment away from their own homes. By this method they could all be treated by their own medical man. Of his 43 cases 42 put on weight and lost all symptoms except in a few where a slight cough remained, and a few bacilli might be found occasionally.

Dr. J. **RIVIÈRE** said that he had been using high frequency currents for more than five years and had had good results with them. He used even more powerful ones than did Mr. Williams.

Dr. D. J. A. **CHOWRY-MUTHU** (Isle of Wight) read a paper on

The Diagnostic Value of Bacilli in Relation to Phthisis.

He related six cases as illustrating this subject. They all presented the clinical appearance of phthisis, but in none of them could the bacillus tuberculosis be demonstrated in the sputum. They all recovered and were found out to be really cases of chronic pneumonia, syphilitic disease of the lung, chronic bronchitis, &c., and one case appeared to be mycotic bronchitis, a large quantity of muco-purulent matter being expectorated which contained mycelial threads. He recognised the difficulty of demonstrating the bacilli in some cases, but thought that if after thorough search they were found to be absent they might provisionally pronounce the case to be non-tuberculous.

Dr. F. W. **FORBES ROSS** (London) thought that the severity of cases of phthisis could not be determined by the number of bacilli present in the sputum. In some cases which, from the point of view of symptoms, had been stationary for years bacilli were very abundant.

Mr. **GRIFFITH C. WILKIN** (Yeovil) read a paper on

Rheumatic Endocarditis.

He related a case of this affection in which the patient was extraordinarily susceptible to the influence of three drugs—morphia, quinine, and nux vomica—given at separate times. One and a half minims of injectio morphinæ hypodermica, B.P., were given for joint pain in the early stages of the disease. The patient became comatose and was only saved from death by large doses of atropine and electricity energetically administered. She shortly afterwards had pneumonia and then left hemiplegia from embolism. Quinine was given but caused intense headache. When she began to recover small doses of tinctura nucis vomicæ, B.P. (five minims), were given three times a day. These caused after a week rigidity and opisthotonos, which only stopped when the nux vomica was discontinued

Dr H J CAMPBELL (Bradford) read a paper on

The Treatment of Cardio-arterial Disease

Diffuse arterio sclerosis caused a disturbance of circulation and nutrition which was temporarily compensated for by cardiac hypertrophy After a time, however, when this had reached its maximum continued high arterial tension was likely to lead to post-hypertrophic degeneration of the cardiac muscle A correct appreciation of the degree of this tension was desirable, and Dr Campbell was accustomed to use Hill and Barnard s sphygmometer for that purpose and considered that it answered very well It did not indeed record very well the extreme degrees of high pressure, but that was of little moment so long as they recognised that the high pressure existed He deprecated routine treatment in these cases, but thought that each should be considered on its own merits Harm might be done in one by treatment which would be quite appropriate in others If kidney sclerosis were also present it additionally complicated matters In this case he was accustomed to rely on an exclusive diet of milk and large doses of sodium iodide

Dr FORBES ROSS read a paper on the Treatment of Tuberculosis by Meat Albumin, which will be found at p 523

Mr STUART LOW (London) read an unannounced paper on the Use of Mucin in Diseases of the Alimentary Tract, and Dr J HADDON (Hawick) one on a Change of Life in Men as well as in Women

Owing to the room allotted to this section having been changed on each day it was very poorly attended on the last day, members not being able to find it

SURGERY

FRIDAY, AUGUST 2ND

Mr HOWARD MARSH (surgeon to St Bartholomew s Hospital London) opened a discussion on

Injuries of Joints with Special Reference to their Immediate and Remote Treatment by Massage and Movement

This subject, he said, was very suitable for discussion at such a meeting as the present Both massage and movements have long been employed in English surgery, but lately they have come into much more general use Both are valuable remedies but if used as a matter of routine both may do great harm As methods of surgical treatment they must always be closely supervised, care being taken to watch their effect, and especially to be sure that no element is present in the case which renders their employment undesirable It is necessary to have a clear idea as to what has been termed the "physiology of massage'—as to the different ways i e, in which it acts 1 It enlarges the amount of blood circulating through the part concerned This is obviously apparent in the skin which instead of remaining cold and pale becomes warm and more or less red The same result was experimentally demonstrated in regard to the muscles by Brunton and Tunnicliffe who showed that the amount of blood passing through them both during massage and after its cessation was increased This increase of blood is in every way advantageous. It maintains or improves the nutrition of all the various tissues, it promotes the restoration of the functional activity of injured muscles and it plays an important part in the absorption of lymph and extravasated blood 2. Its action is mechanical By kneading and percussion extravasated blood and lymph which have coagulated in the tissues and led to brawny œdema are broken up and dislodged while by stroking from below upwards they are swept onwards and brought within the reach of healthy lymphatics and a normal venous circulation, so that they can more readily be absorbed 3. It is an efficient stimulant to damaged muscles through its influence on the nervous system In such minor injuries as sprains and contusions probably the small nerves ramifying in the injured part are seldom torn across, for they are tough rather than brittle, they are well protected in the subcutaneous tissue and the deeper structures and their course is often tortuous so that they are not easily put on the stretch Nevertheless they are not infrequently so far injured that their functions for the time being are more or less suspended, and massage is then a very useful agent in stimulating them to a resumption of activity It probably acts in a similar manner on the vaso-motor nerves which preside over the arterial system of the part 4 No one who has watched its sedative effect when applied in cases of recent injury can doubt the influence of massage in reducing muscular spasm and relieving pain Here it must be used very gently and be limited to stroking and light friction for short periods three or four times a day. 5 Probably massage promotes the absorption of recently formed adhesions provided they are not too extensive and firm This is a matter of considerable interest. Just as provisional callus, formed in the repair of fractures is absorbed, so is the new connective tissue which is developed after injury of the soft parts Perhaps the most obvious instance of this is met with in the case of adhesions following peritonitis Often even extensive adhesions gradually yet completely disappear, probably as the result of constant disturbance and traction during peristalsis Much the same result is produced by what may be termed the interstitial disturbance and traction which take place during the different movements employed in massage As to movements these are of three kinds those performed under an anæsthetic, passive movements and voluntary movements on the part of the patient often carried out against resistance As to movements under an anæsthetic they can be safely applied only when a careful diagnosis has been made In the first place it must be ascertained that the joint itself is not, nor has been actively diseased, so that it has undergone no considerable structural changes such as follow tubercle, or osteo arthritis septicæmia or locomotor ataxia The cases in which this form of movement is most successful are those in which the joint itself is practically healthy while it is hampered by changes in the parts around. Passive movements are chiefly useful in restoring movements that have been lost or in preventing stiffness in joints which are to be long disused—for instance, a healthy ankle—the patient having disease of the hip or the knee Voluntary movements on the part of the patient, especially when performed against resistance, are in many instances more valuable than massage Several forms of apparatus have been introduced for use in these movements and many of them are very satisfactory In all cases however, efficient supervision must be maintained Diagnosis is of course of essential importance It cannot always be exact, but it must be carried far enough to indicate that the case belongs to the general class in which these agents are useful and that no element is present which renders them unsuitable The conditions for which massage and movements are most useful are sprains and contusions of previously healthy joints unattended with any serious complication such as dislocation or fracture, any wide laceration of muscle, rupture or displacement of tendons, or such pre-existent conditions as tubercle, gout, or hæmophilia The treatment of recent fractures by massage was so fully discussed at the meeting last year at Ipswich that it is needless to consider it now The after treatment of dislocations has of late years undergone a great and very advantageous change In the case e g of the shoulder the arm is no longer bandaged to the side for a fortnight or three weeks, but passive movements and massage are regularly used after the second or third day He had seen a patient thus treated able to move his arm freely in every direction in the course of three weeks He had also seen a patient walk freely and without lameness three week after the reduction of a dislocation of the hip The chief symptoms which indicate the use of massage and movements are stiffness and pain but before they are employed the cause of the symptoms must be ascertained as to whether the mischief is inside or around the joints Take the shoulder The arm may be stiff and there may be severe pain and marked muscular wasting Is this a case of disease of the joint itself or of adhesions outside? There is, he believed only one test to be relied on to determine this question This is to ascertain whether the joint is as stiff as it at first sight appears to be, or whether, within certain limits movements are free and smooth. If these free and smooth movements limited though they be—are present the fact is a strong indication that the joint is sound and that the symptoms depend on surrounding adhesions. (Cases in illustration were related) As to pain it is very important to remember that it cannot be used to differentiate between real joint disease and surrounding adhesions Indeed in many cases pain due to adhesions is more severe than that produced by joint disease Muscular wasting—a principal symptom in disease of a joint—may be present though the case is one of mere adhesions in the capsule and surrounding parts. In some instances movement under an anæsthetic will produce a cure which there seemed at first sight no reason to anticipate, for though the patient complains of "weakness" and pain in the joint there is no appreciable stiffness or any condition for which movement and massage seem called for. These cases, which bonesetters not rarely cure by moving them as they move all others, are instances of slight adhesions which cannot be detected but which are yet sufficient to make the patient walk with lameness and "weakness" of the joints concerned. (Cases were related to illustrate this group.)

Mr. R. H. A. Whitelocke (Oxford) spoke of the treatment of injuries to the healthy joints of young adolescents—Oxford athletes. He agreed with the necessity of particularity in diagnosis. In simple sprain with stretching of ligaments which were seen at once he was accustomed to apply elastic pressure by cotton-wool and massage, with a result that the limb was fit for use and sport in three weeks' time. In slight lacerations around the joint he was accustomed to use movement under an anæsthetic to free the articular surfaces from any synovial remnants, then to apply pressure, and in 24 hours himself to move the joint passively and gently massage, but he would allow no active movements until the lapse of 14 days. He rejected the use of rigid apparatus. He remarked that he had to deal with intelligent people who would satisfactorily conform to the treatment. In remote injuries, such as had been treated with rigid apparatus, he thought that adhesions were formed by the organisation of blood-clot which always was present in serious strains, so that unless the movement was early adhesions and stiffness resulted. Often the pain and stiffness were referable to a rheumatic tendency which salicylates rapidly alleviated.

Mr. F. F. Burghard (London) agreed in the use of early passive movements in the shoulder-joint, &c., and the badness of prolonged fixation. Movement removed the liability to fixation. He believed in the frequency of movement under an anæsthetic and a gentle attempt to break down the adhesions each week rather than one vigorous attempt. He had formerly used elastic pressure in recent cases, but now he had discarded it and relied on massage alone.

Dr. J. Ward Cousins (Portsmouth) remarked on the necessity of treating the slight abrasions present in contusions around joints; these were very liable to septic infection in the poor. He believed in an immediate use of the antiseptic bath. He also noted the importance of slight injuries in diathetic subjects, tubercle in the young, and gout in the old; for the latter he found the hot-air bath useful. In general cases he preferred rest for a few days, then massage to the muscles and tendon sheaths, and to leave the joint itself alone. He strongly objected to the probing of wounds around joints; the application of antiseptic dressings was all that was required.

Mr. H. Gilbert Barling (Birmingham) agreed that there had been too much fixation in the past and believed in early movements with elastic pressure; the latter, he thought, might express accumulated fluid. He confessed he could not, like Mr. Whitelocke, get patients well in three weeks; if he could he would not let them then indulge in athletics, for he believed all such injuries to arise from a state of "out-of-condition" of the muscles. He believed it was better not to use splints in Colles's fracture with moderate deformity; he would ignore the deformity and seek for mobility. He narrated two cases of lady pianists where with no other fixation than that of a sling with passive movements in two days and active movement in a week he had had such good results that the piano could be played in three months.

Mr. J. Paul Bush (Bristol), referring to Mr. Whitelocke's remarks, said that he had seen no such speedy results amongst the soldiers in South Africa, even in carefully selected cases.

Mr. J. R. Morison (Newcastle-on-Tyne) said that he must strike a discordant note. In talking of treatment they were in danger of forgetting pathology. To prevent inflammation was to prevent adhesions. Many so-called injuries to joints were not connected with the joints at all but with their surroundings. He used to suture with gut the fractured patella, not irrigate, and to rest the joint for six weeks, getting a better result by such means than others with wiring and early passive movements. In miners displacement of the semilunar cartilages was frequent and to them such a joint was useless without excision of the loose body; he then gave rest for a month and got good results. When there was a definite organic injury to a joint rest was essential. He thought that elastic pressure was good. He noted a curious case of severe pain in the wrist following on strain without obvious defect; he thought neurosis might account for it and he had procured relief by heroic doses of the interrupted current.

Mr. Howard Marsh, in replying, said that he believed in elastic pressure; probably there was only support of relaxed vessels and so prevention of effusion. As regards quite early movements he was at issue with Mr. Morison. In some 80 to 90 cases of excision of the semilunar cartilage he had removed the splint in about a week when the wound was healed and commenced massage to the muscles. In the next week active movements were allowed, and in the succeeding two or three weeks the patient was up and about, so that in two months he was at work again. So with the patella, but in this case he did not allow the patient out without a knee-support for two or three months. Replying to Mr. Burghard, he thought that all adhesions should be broken down at one time. He agreed with Dr. Cousins regarding antisepsis and with Mr. Barling regarding the connexion of sprains with loss of muscle-tone. In cases of slipping of the semilunar cartilages of the knee massage should be adopted and never plaster supports. He believed in splintless Colles's fracture treatment; in cases where such fractures turned out badly it was not from deformity *per se* but from matting of structures.

Mr. F. F. Burghard read a paper on

The Treatment—Non-operative and Operative—of Congenital Dislocation of the Hip.

At the outset he deprecated sweeping statements regarding this deformity, different conditions requiring different measures. Discussing the anatomical features of the state he said that the dislocation on the dorsum ilii was not so invariable as was thought; it might succeed a much slighter displacement under the anterior superior iliac spine. The increase in the angle made by the long axis of the femoral neck with the transverse axis of the condyles was increased from a normal of from 25° to 30° to as great as from 100° to 150°; this twisting was such that the limb was rotated inwards when the head was properly in the acetabulum. The diminution of the angle of the neck with the shaft of the femur from a normal of from 110° to 140° to as little as 90° was proportional with the length of time during which the child had walked. A point which was noted by Hoffa, to which was due the ultimate failure of apparently successful operations, was the hour-glass shape assumed by the capsule, owing to the passage over it of the ilio-psoas tendon, and the exceedingly dense, unyielding character of the part over the acetabulum owing to the thickening of the capsular bands. The treatments by the apparatus of Hoffa, of Hoffa-Mikulicz, and of Schede were discussed and their insufficiency was shown. The bloodless or extension method of Lorenz was also shown to be in the majority of cases a failure, even in the hands of its author. Of the operative measures he gave his experience of Hoffa's, Lane's, and Paci's methods, their indifferent success, and stated his belief that the cause of this in many cases was that the head of the bone must lie over the acetabulum with a portion of the capsule or even ligamentum teres interposed between it and the bone. In several cases it was impossible to force the head of the femur through the narrow capsular constriction referred to without enlarging the orifice. He described a mode of operation which had been attended with much success. At a preliminary sitting the femur was freed sufficiently to get the trochanter down to Nélaton's line and for abduction to 90°. By a curved incision the fascia and tensor vaginæ femoris were freed from the ilium, the limb was rotated outwards, and the capsule was incised parallel and internal to the anterior spiral line. The tendon of the ilio-psoas was freed and the attachment of the capsule to the front of the acetabulum and the rectus tendon was also freed; now on manipulation by Lorenz's method the head at once entered the acetabulum. All that now remained was to excise an elliptical portion of the redundant anterior part of the capsule, which was tightly sutured by catgut, and the joint was stable. The deep structures were united by one or two catgut sutures. The limb was put up in a form of Croft's plaster splint and after a month a skiagram was taken, when it was seen that the head of the femur was in excellent position. In six months the child was allowed to walk with a thick sole on the sound side and now, 18 months after, the child was perfectly cured and the head of the bone was in place Four other cases had been operated on with equal success, all of the patients were under six years of age. He noted the necessity of selection of cases and their early recognition and treatment. He concluded with a classification of cases in groups arranged according to the applicability of the various methods of treatment described.

Mr HOWARD MARSH said that he had felt the unsatisfactoriness of such cases though the operative procedure that had been described that day helped matters on very satisfactorily He remarked that a case which had been *much vaunted as a cure by extension* had been submitted to him without his knowledge of the previous history, he had found the condition to be that of an absolutely untouched congenital dislocation He agreed to the frequency of dislocation under the anterior superior spine. If the head was fixed in a pseudo joint and was not sliding he thought that operation would do no good, it was urgently necessary where there were much displacement upward and backward and a sliding condition here patients were hopelessly lame He remarked that the ill-development of the limb and muscles of such cases was a great drawback and he noted one feature of the paper—the definite examination of the anatomical condition and the operative treatment accordingly

Mr R. H A. WHITELOCKE read a paper on

A Case of Hydatid of the Right Pleura successfully treated by Operation.

The case was that of a woman, aged 28 years a resident of Abingdon Symptoms of pleurisy appeared in March 1900 In June a swelling appeared in the eighth right intercostal space In July she was operated upon, parts of two ribs were resected and the cavity was opened *and drained*, the *fluid* was straw coloured and contained cysts. Cysts were discharged from the wound until December, when Mr P Martin secured the edge of the mother cyst and drew it out entire The points of the case were the patient had never been out of England, the rarity of cases under such circumstances and especially of infection of the pleura, also the complete absence of pulmonary symptoms

Dr J MICHIE (Adelaide) had frequently seen similar cases in Adelaide, it was not uncommon to get long continued discharge of the daughter cysts

Mr JAMES RANKIN (Kilmarnock) read a paper describing an operation for

Senile Gangrene

in a man, aged 72 years There was a rapidly spreading gangrene of the foot spreading from around an ingrowing toe nail. The leg was amputated by Stephen Smith's disarticulation at the knee by lateral flaps The result was perfect The old man devised his own pin leg and contemplated returning to work.

Mr R C CHICKEN (Nottingham) read a note and showed a specimen of

Loose Bodies from the Knee-joint

The case had been undiagnosed for a long time and was supposed to be old standing disease of the joint. He suspected loose bodies, opened the joint and removed 67 soft cartilaginous loose bodies weighing together one ounce He was inclined to think that loose bodies were more frequently multiple than single

Dr ELIZA L. WALKER DUNBAR (Bristol) read a paper on

Reducibility of Long standing Dislocations

The paper described a case of partial dislocation of the right hip-joint which after existing five years was reduced without difficulty under anæsthesia showing that the joint had in no way become blocked The patient was a woman aged 31 years A skiagram of the case was shown The symptoms were *greater length of the leg by half an inch*, absence of power by everting the foot, insecurity in standing and walking requiring assistance of a staff, and pain after exertion Reduction was followed by great relief and free use of the limb During three years since reduction dislocation had threatened three or four times and movement had been somewhat impeded until passive movements—the necessity for which had been impressed on the patient at the time of treatment—were carried out, this restored the normal condition Another case, one of rarer occurrence, was partial dislocation of the right sacro-iliac joint. The dislocation had existed for six years causing incessant discomfort and acute pain after rising from a sitting posture and in turning round when lying down. The patient was a woman, aged 32 years The dislocation, which was shown in a skiagram, had been produced by lifting hastily a heavy scuttleful of coal It was reduced under anæsthesia as shown by a skiagram and kept well in place with complete relief for 15 months Then one day after walking up stairs the patient thought that she felt the joint give way Pain did not come on for 14 days, when the old discomfort set in The dislocation was reduced again as soon as the patient applied for advice The relief was quite perfect Both cases were treated without splint or bandage The first was *massaged, whilst passive and active movements* were carried out from the first day for one month The second case was dismissed in 10 days

STATE MEDICINE

FRIDAY AUGUST 2ND

The final meeting of this section commenced with the reading of some notes by Mr J A. WANKLYN (London) upon

Recently examined Arsenical Beers

He held that the failure to recognise the presence of arsenic in beer to a great extent depended in the recent arsenical epidemic on the abandonment of the original Marsh's process and on the protean powers of combination possessed by arsenic It was known that two grains of arsenic in the shape of arsenious acid had proved a fatal dose, but 15 grains of arsenic in the shape of cacodylic acid or cacodylate of soda were not fatal and indeed, had been taken without manifest ill effect Mr Wanklyn exhibited specimens of cacodyl and cacodyl red pigment and mentioned that they were extremely rare

Dr T M LEGGE (Inspector of Factories) addressed the meeting on the subject of

The Diseases of Occupations

He said that the anomalies in trade diseases—viz, the difference of the symptoms produced among workers making or using poisonous materials from those produced by their medicinal exhibition—were very striking The manufacture of potassium cyanide for example, appeared to be almost if not quite innocuous In the manufacture of potassium bichromate the lesions were limited There was no evidence that chromic acid dust penetrated to the lungs Amongst workers with arsenic the symptoms of neuritis were absent In hatters' and furriers processes where rabbit skins were brushed with nitrate of mercury, salivation was rare, though tremor was a prominent symptom, and there was in addition marked erosion of the teeth due to the acid fumes There had been given no adequate explanation why the continued inhalation of the fumes of yellow phosphorus should be limited to the maxillary bones for satisfactory evidence was lacking that anything in the nature of phosphorism was produced In regard to anthrax workers in wool horsehair and hide industries seemed to bear an almost charmed life If the contention were right that the incidence of tetanus on jute workers was due to spores imported in incredible numbers it was surprising that cases following on lacerated wounds in jute mills were not more frequent, that must be attributed to the natural immunity of the human subject to tetanus In factories where lead was used it was right to be on guard against attributing every case of anæmia in youthful workers to their employment One of the most difficult points in industrial disease was to estimate rightly the effect of the inhalation of dust on the lungs and the relation of fibroid phthisis to true phthisis With the exception of mineral dust containing a high percentage of silica steel dust, flax and of a few others evidence had not been made very clear of injury to the lungs *from many* kinds of dust. Attention was called to the pneumonia induced by the inhalation of basic slag dust, there was nothing in the composition of the dust apart from its fine division to render it particularly injurious Referring to the notification required of every case of lead arsenic phosphorus, or mercurial poisoning, and of anthrax contracted in a factory, Dr Legge pointed out that medical practitioners who notified cases of lead poisoning from drinking water or in a house painter engaged entirely in outside work might think it pedantic to draw a distinction between notifiable and non notifiable lead poisoning but the whole point of the distinction was to obtain a clue only to those cases in premises under the Factory Act. In lead-poisoning it might fairly be assumed that each case on an average entailed an absence from work for one week, and the absence from work from the effects of lead alone during last year if compressed into the life of a single man would mean absence from work for 19 years. The proportion of severe cases of lead-poisoning among file-cutters and those engaged in coach painting, in ship-building, &c., exceeded that of those engaged in industries where the danger was primarily from the dust of salts of lead. The official reports brought out the fact that saturnine palsy was essentially an affection of the male sex, while headache, anæmia, and encephalopathy were more common in the female sex. Notification had been especially useful in obtaining knowledge of sources, hitherto unsuspected, in which mercurial and arsenical poisonings were likely to arise. Anthrax was, however, the most protean in its manifestations of all trade diseases and was the most difficult to control. Disinfection by steam of horsehair in hydraulicly pressed bales was impossible. In the cases of anthrax which had been notified one point was noteworthy. The accepted treatment was excision of the pustule as soon as it was diagnosed; in country districts there was reluctance to operate and treatment was limited to the application of caustics or hypodermic injections of pure carbolic acid, and it had to be admitted that that treatment had been successful. In one country village five successive cases had recovered without operation, but, on the other hand, in Bradford and Sheffield fatal cases had as a rule been those in which there had been delay in having the pustule excised. All accurate knowledge of the diseases of occupations must come from the medical profession and by the writings of medical men great assistance had been rendered in pointing out the dangers attaching to various occupations. Though he had never yet come across a certifying surgeon who was not interested in his work it had appeared to him that as a body they were lacking in *esprit de corps*.

Dr. W. MURRAY (Birmingham) contributed a paper on

Chronic Brass Poisoning.

He said that too little attention had been paid to the poisoning that affected many persons engaged in the manufacture of raw brass. Though "brass-founder's ague" had been known a long time the far commoner cases of disease from prolonged absorption of brass dust had attracted little notice. The state of unhealthiness produced in brass working presented a uniformity in its train of symptoms that suggested the action of a specific poison producing a specific disease. The illness was ushered in with anæmia and malaise and as the disease progressed the complexion assumed a sallow appearance and emaciation became a prominent feature. Muscular tremors occurred and the digestion was impaired. There was a metallic taste in the mouth and the breath emitted a disagreeable metallic odour. Nervousness, faintness, profuse sweating, and cold sensations were very troublesome features. The indication of copper absorption—viz., a green line at the bases of the teeth—was present in all these cases. The sweat might have a greenish tint and this colour was sometimes very marked in the hoary hair of old workmen. Skin symptoms were sometimes produced from the brass dust or the irritative action of the sweat impregnated with copper salts. To diagnose this disease from consumption the chest on examination showed no lesion that was discoverable except occasionally a bronchial catarrh. Some authorities said that the disease was caused by copper, others by zinc, and it had been attributed to lead and arsenic as impurities, but that was visionary. The symptoms of brass poisoning were not those of lead or arsenic poisoning. Pseudo tabes had been recorded as resulting from brass absorption, but the symptoms were easily differentiated from the typical symptoms of brass poisoning. There was sufficient similarity between poisoning by copper and by brass to justify the hypothesis that copper was the principal metal at fault in disease from brass poisoning. The poison gained ingress by the digestive and respiratory tracts, the fine dust setting up respiratory affections ending in fibrosis of the lung. In the stomach the dust was acted upon by the gastric juice yielding soluble salts leading to the general condition. The dust was ingested by taking food with unwashed hands or in the work-rooms. The treatment recommended by Dr. Murray was phosphorus one-thirtieth of a grain in pill or phosphoric acid coloured and flavoured. It was to be regretted that the special rules applied to the casting and mixing shops were not applied to the other departments of brass working. At least the free dust in the workroom should be reduced to a minimum, efficient ventilation should b provided, cleanliness on the part of the workers should b enforced, and eating in the workshops should be prohibited.

Mr. H. D'ARCY ELLIS (Stourbridge) communicated paper on

Glass Polishing.

Glass polishing, Mr. Ellis explained, was the final stage of glass cutting. The glass cutter polished the glass on which he had himself cut designs and used a mixture for polishing known as "putty powder." From the use of this powder cases of lead-poisoning arose. A good putty mixture contained—lead, 112 pounds; tin, 25 pounds; antimony, three pounds; and bismuth, from two to three ounces. The "putty powder" for large glass work was dabbed on a revolving polishing wheel, but for very fine work the powder wa applied by brushes. In some cases a boy stood in front of, an at the side of, the brush to apply, the putty powder and wa splashed with the mixture flying off the brush. This was the most dangerous period, in the opinion of the workman. After the polishing of the glass by the putty, girls were employed as "wipers-out," and some of these had been known to suffer from lead-poisoning. Mr. Ellis then proceeded to relate illustrative examples of cases, fatal and otherwise, of lead-poisoning which had occurred in his practice from the putty powder. It was a serious thing to advise a man to give up the only trade by which he could earn a living. His chance of earning a living at any other occupation was generally extremely small. The isolation of every susceptible worker was an extreme remedy which would be strongly resented. The obvious remedy was to find the minimum of risk and endeavour to enforce its application. In consequence of legislation already in operation the cases of lead-poisoning had diminished, practically leaving only th chronic cases. To the question, Could anything more b done? Mr. Ellis replied that greater attention to detail was all that was needed, personal cleanliness, ventilation, and tidiness in the workshop. A separate apron should be worn at the putty frames which were now used at the wheels and taken off when the polishing was finished.

Mr. W. F. DEARDEN (Manchester) delivered an address on

The Causation of Phosphorus Necrosis.

During the last 20 years it was known that 102 definite cases of phosphorus necrosis had occurred in this country. There were two varieties of matches with which they were particularly concerned—the English or paraffin dip match and the Belgian or sulphur dip match; the latter was on the continent popularly termed "stinkstecher." The fulminating composition for this latter contained 30 per cent. of yellow phosphorus, the English match contained about 5 per cent. The dangerous parts of the manufacture were the mixing o the phosphorus paste and the dipping, drying, and boxing of the matches. The paste was usually mixed in a steam-jacketed pan with a removable lid, the dipping was done by pressing the matches on to the mixture spread out on a heated slab, the drying was effected by placing the matches in a heated chamber, and the boxing was carried out by girls and women. The dangerous factor in the processes was the giving off of fumes of the lower oxide of phosphorus (P_4O_6) from the moist heated paste in the mixing, dipping, and drying departments and from the moist heads of the matches when in a proper condition for boxing. This lower oxide of phosphorus mixed with the saliva in the mouth and was also inhaled directly into the lungs. The soiling of the hands and clothes w the paste also constituted a certain amount of danger. M Dearden agreed with the opinion of Lorinser that the fum exerted their evil office by the blood becoming surcharge with phosphorus, which in turn had an affinity for bone, an as a consequence weakened the resisting power of this tissue to local injury, this local injury in the case of the jaw-bone being supplied through the medium of a carious tooth. Mr. Dearden reviewed the arguments that constitute presumptive evidence of the existence of some systematic predisposing influence as a necessary adjunct to the local excitation. In giving the positive evidence of a more general action exerted by phosphorus on the tissues Mr. Dearden mentioned that it was perfectly evident that in the course of years a comparatively large amount of the fumes must be inhaled into the lungs and that phosphorus or some combination of this drug must by that means get into the circulation. He had noticed the characteristic odour in the breath of girls several days after they had been suspended from work under the special rules. The condition brought about by the mild saturation of the system with some compound of phosphorus predisposing to necrosis of the jaw influenced bone-tissue generally and was chemical in its nature. It had been concluded that bone formed in young people working at phosphorus was much denser in character than it would otherwise be It was therefore to be held that changes did take place in bone-tissue from inhalation of phosphorus fumes, and it was reasonable to explain "phossy jaw" as arising from local irritation through a carious tooth acting on bone already damaged as the result of a general infection The principle upon which all general precautions must be based aimed at a minimum exposure of the worker to the fumes, [illegible] the general infection of the system, and [illegible] on by proc[illegible]

Dr. G. REID (Stafford) read a paper on the

Infant Mortality and the Employment of Married Women in Factories

Dr. Reid, after discussing the prominent place which must be given to ignorance on the part of mothers regarding the essentials of infants' diet as one of the factors for the continued high rate of infant mortality, passed on to the question of the marked difference in the infant mortality rate of the northern and southern towns of the county of Stafford. The northern towns in question contained large numbers of married women engaged in factories. He classified the purely artisan towns in the county into three groups: (1) many married women workers; (2) a good number of married women workers; and (3) practically no married women workers He found that the diversity in the infant mortality rate based merely upon the geographical division was intensified, and that there was a very marked gradation in the rate which accorded with the relative proportion of married women workers There had been a general increase in the infant death-rate in recent years and practically the same relative proportion had been maintained in the three groups of towns They had to devise means for wiping out an increase in the infant mortality of nearly 27 per cent. in those artisan towns in which married women were largely engaged in factory labour. Would it be unreasonable to have a condition made in such cases that the child should during the absence of the mother be placed under such care as should afford a reasonable prospect of its wants being provided for? The present law imposed certain restrictions, but those in effect benefited the mother rather than the child. It was illegal for the mother to return to work within one month of her confinement, but it was hardly likely that she would commence suckling her child if she intended to engage in work again after so short a period Dr. Reid suggested that this time limit should be extended to three months because the probability was that the mother in most cases would then suckle her child until she returned to work and thus the most precarious period in the life of the child would be tided over and the chances of subsequent survival would be considerably increased. Dr. Reid concluded by advocating the establishment of *crèches* by local authorities.

Dr. C A. GREAVES (Derby) communicated a memorandum, entitled,

Plumbism Cases in Carriage Works.

Dr. Greaves had reported 60 cases of plumbism in the last three years, of which number 42 cases were in carriage-building works 14 of these were workmen not employed in the paint-shops but working as coach body-makers They used a good deal of paint for coating the parts of the woodwork and some white lead to fill in crevices. A point which he considered of importance was the advisability of clearing the nasal passages by blowing the nose well before meals, as he had found reason to believe that the workmen who had to burn off old paint were liable to take in a good deal of volatilised lead in the fumes and dust which they inhaled Dr. Greaves protested against lemonade being considered a preventive of plumbism; the fallacy arose because a drink containing a dilute sulphuric acid forming an insoluble sulphate of lead had been foolishly called lemonade, whereas real lemonade contained citric acid which was useless, because citrate of lead was fairly soluble. He had seen a few cases of plumbism in brass finishers traceable to the filing of soft brass castings containing as much as 5 per cent. of lead.

Dr. C. R. DRYSDALE (London) contributed a paper on

Lower Birth-rates considered as the Real Cause of Lower Death-rates

Dr. Drysdale quoted statistics to show that the high death-rates of the poorest classes were due to their very high birth-rate, which forced them to crowd into purlieus and exposed them to semi-starvation. He considered himself entitled to say that the real cause of high death-rates in this country were high birth-rates, and that if they really wished to improve the health of the classes at the bottom of society they must in future endeavour to persuade them to have families of not more than four children as a maximum, or, better still, to content themselves with two children or thereabouts until the mortality of the worst-paid classes should fall to 12 per 1000, the present death-rate in well-to-do Hampstead

Dr. A. K CHALMERS (Glasgow) proposed and Dr. G. REID (Stafford) seconded the following motions which were carried —

That this section expresses its satisfaction [illegible] for the Home Department.

That inasmuch as notice has been given of amendment of the pro- [illegible] resolution and to communicate it [illegible] Home Department

The work of the section concluded with the reading of a paper by Mr. P TARGETT ADAMS, late assistant port health officer at Bombay, on

Port Sanitary Administration and the Control of Plague in the Port of Bombay.

Mr. Adams described the methods adopted at Bombay for the preventing of the spreading of plague to ports out of India. No small measure of praise was due to Colonel Macartie and Major J Crimmin, I M.S, V.C., for so far preventing the extension of plague from a city saturated with the infection of plague and in such constant intercommunication with ports all over the world and Europe in particular He believed he was correct in saying that from the port of Bombay plague had rarely been shown to have been imported at all and in no case by means of rats In those few cases in which importation in a sporadic form occurred it had been due to the conveyance of the infective material from Bombay by means of infected clothing or an infected patient Important as the transmission of plague by means of rats and their parasites was it was equally necessary to remember that filthy clothing charged with moisture and organic matter and stuffed into a filthy box in the very warm atmosphere of a forecastle was probably as dangerous and certain a means for the successful importation of plague as the rat and its fleas

The proceedings of the section terminated with a vote of thanks to the President, Mr. Shirley Murphy. In the passing of this vote of thanks Mr. W. C. C. PAKES (London) pointed out that the President had never delegated the chairmanship for one instant during the whole course of the meeting

---

PSYCHOLOGICAL MEDICINE.

FRIDAY, AUGUST 2ND

Dr FRANCIS WARNER (London) opened a discussion on

The Diagnosis and Treatment of Feeble minded Children

The Elementary Education (Defective and Epileptic Children) Act of 1899 had directed attention in many quarters to the necessity of provision for the care and training of children of defective brain power The Act was permissive and the children to be provided for were defined as not imbecile and not merely dull or backward but defective—that was to say, children who, by reason of mental or physical defect, were incapable of receiving proper benefit from the instruction in the ordinary public elementary schools, but were not incapable by reason of such defect of receiving benefit from instruction in special classes or schools as were in the Act mentioned, &c. There was great need of a wider knowledge and study of defective children so that the mental physician might be able to afford help to parents and teachers Of the school children between the ages of three and 13 years in England it was estimated that about 1 per cent were feeble-minded In the diagnosis of brain defect they had to look for certain signs—e g, developmental and physiognomical features, nerve-signs or attitudes and movements, the condition of the organs of special sense, and the state of general bodily health In the process of examining and questioning the child some general estimation should also be made of its mental grade. The volume and shape of the head, irregularity and asymmetry of the skull, disproportion between cranial and facial development, defective development of the nares and palate with obstruction of nasal breathing, malformations of the ears, eyes, and mouth, were all significant. In the face expression might be wanting, twitchings of the muscles and "tics" might be conspicuously present, an incapacity for fixation of the eyes and of attention, and a lack of control and coördination in the movements of the hands might be observed. Spontaneity of movement, which was so essentially characteristic of normal children, might be wanting and might be replaced by monotonous grinning, grimaces, athetoid movements, shruggings and swayings of the body, and the like. Emotional re-action to a stimulus might be excessive, as in chorea. It was the coördinated movements seen, first under direction, but later as a self-contained power, that mostly indicated good brain power. As regarded treatment the aim was to remove abnormal nerve-signs and to promote the normal processes of spontaneity and controllability of movements—i.e., to implant modes of action and response which were essential to self-help and social life. Play, games, general activity, and the prevention of loafing encouraged spontaneity and variety in movements and tended also to remove the awkward habits or repetitive "automatic actions" which were frequent among defective children. Imitation of the teacher's movements was most useful in early training, far more so than clay modelling and drawing. Exercises in hand and finger movements cultivated facility for mental action and the appreciation of numbers. Writing should follow as a natural sequel. Eye movements needed training to bring them under such control as was necessary in acts of attention. The cultivation of the muscular sense in estimating the weights, sizes, and shapes of objects, and in comparing and contrasting objects was a point of the highest practical importance Speech and articulation should be taught by close imitation of the teacher's method of producing elementary sounds, and breathing exercises should be practised as an aid to voice-production. The recognition and naming of colours and the reading of time by the clock would often be learnt by practice. Myopia or deafness should be corrected. Obstructions in the nose and throat might be a cause of stupidity.

In the discussion which followed the above paper,

Dr. G. E. SHUTTLEWORTH (Richmond) said that in drawing conclusions too much stress should not be laid on any *single* sign. Regard should be had to physiognomy, developmental features, nerve signs, defects of bodily nutrition, and the manner of response to questions or orders. Idiocy, imbecility, and weak-mindedness were three grades of mental defect which shaded into each other. If marked mental incapacity and faulty habits existed so that the child was regarded as more properly requiring medical care and nursing supervision it was better to certify such a case as imbecile, which would exempt the child from school and help to gain his admission to an asylum for imbeciles, where, in addition to medical care, training suitable to the case would be applied. Defective children of the "Mongol" type were found by experience to be imbecile and incapable of benefiting by instruction, especially as in many such cases marked incapacity for instruction was present though they had imitative tendencies in some degree. Children with inherited syphilis proved unsatisfactory pupils as a rule, and most unsatisfactory of all were children of the morally defective type. Imitation of the teacher was useful, but the teacher should not be fatigued and worn out or he would be a bad model.

Dr. F. M. POPE (Leicester) believed that conversation with the child for a few minutes would afford a more correct estimate of its capacities than the examination of its physical "stigmata" or defects.

Dr. FLETCHER BEACH (London) was of opinion that the arrangements made in London, Leicester, and other towns for the education of feeble-minded children should be extended throughout the country. As regarded moral imbeciles, they were very difficult to deal with. They were unsuitable for schools and should be placed in special institutions, as recommended by Morel of Belgium. If permitted to be at large they propagated illegitimately and produced a vicious criminal and neurotic offspring.

Dr. HENRY ASHBY (Manchester) thought that only the better class of defective children should be sent to special schools, as children on the borderland of imbecility were unsuited.

Dr. LLOYD ANDRIEZEN (London) emphasised the importance of developing the kinæsthetic activities (manual and industrial training), and the excellent results obtained at Elmira and other places in the treatment of young adult criminals and defectives between the ages of 16 years and 30 years by perseverance in this. He cited instances of "tics" and faulty habits being acquired by children imitating their mothers, &c., and was of opinion that special institutions for moral imbeciles and lower grade degenerates were necessary if they were to treat satisfactorily such cases, which were unsuitable in school and dangerous to the community at large if allowed to go about to breed offspring of an insane or mentally or depraved kind.

Dr. EDWIN B. ANGELL (Rochester, New York) referred to the significance of the anatomical stigmata of degeneracy and to their importance when several were present in any child. At Bicêtre, Paris, he had seen remarkable results for good in the long-continued and persevering teaching and training of imbeciles which Dr. Bourneville adopted.

Dr. T. CLAYE SHAW (London) read a paper on

Colitis or Asylum Dysentery.

He contended that only a certain small proportion of cases of colitis were primarily of bacterial origin and that ulceration of the mucous membrane of the intestine was commonly met with in the insane and was a trophic degeneration dependent upon the low nervous vitality of the patient, and that such ulcerations might be comparable to bed sores. The disease known as asylum dysentery seldom affected the medical or nursing staff of asylums. The continued occurrence of colitis in asylums did not imply that sanitation was bad in the wards and buildings where it occurred and cast no discredit on the medical or administrative staff.

In the discussion which followed,

The PRESIDENT (Dr. J. B. SPENCE, Lichfield) asked how the prevalence of colitis in asylums that had only been recently constructed could be explained.

Dr. LLOYD ANDRIEZEN agreed that two factors were possible in the production of ulcerations of the bowels generally in insane patients—namely, infection and trophic degeneration. Colitis, however, was a special form characterised by the presence of blood, mucus, more or less extensive sloughings of the mucous coats of the large bowel, and intense tenesmus.

Dr. EDWIN GOODALL (Carmarthen) believed that while some cases of asylum diarrhœa were not due to dysentery, others were of a specific dysenteric character. He believed that overcrowding was by no means proved to be the cause.

Dr. HARRY CAMPBELL (London) asked whether the eliminations of toxins from the blood into the alimentary canal might not be a cause of ulceration of the mucous membrane of the bowel and whether right-sided colotomy would be advisable.

Dr. J. G. HAVELOCK (Montrose) had seen outbreaks of diarrhœa, but not of colitis, at Montrose Asylum. He thought that the ulcerations and bowel lesions of dysentery were the result of nerve degeneration.

Dr. R. H. STEEN (Chichester) contributed a paper on Modern Plans in Asylums, referring more particularly to such matters as the provision for bathing, dining rooms, and as to the dispositions of the wards, whether they should be aggregated or built in detached blocks on the villa system.

Dr. LLOYD ANDRIEZEN contributed a paper on the Psychology of the Degenerate with remarks on Treatment.

The meeting of the section then closed with a vote of thanks to the President.

PATHOLOGY AND BACTERIOLOGY.

FRIDAY, AUGUST 2ND.

Mr. ALEXANDER G. R. FOULERTON (London) and Mr. W. T. HILLIER (St. Albans) communicated a paper on

The Condition of the Urine in Tuberculous Infection.[1]

Specimens of urine from 25 cases of chronic pulmonary phthisis in the third stage had been examined, the presence of bacillus tuberculosis in the sputum being verified in each case. Six chemical examinations were made of the daily secretion in each case. Albumin was absent in 16, present in small indefinite quantities in eight, and present as more than a trace in one The albuminuria in the eight cases in which traces only were found was irregular in its occurrence, not being constantly present in any of them Accurate estimations of the urea excretion were made in eight cases, and the daily amount was found to vary within wide limits in different cases, the authors had not been able as yet to correlate excess or deficiency in the daily urea excretion with any clinical conditions in these cases The urine had been tested for the diazo reaction in every case and the reaction was obtained in four out of 12 cases in which the patients had died whilst still under observation, and in three out of 13 cases in which the patients were discharged from hospital alive As in the case of the albuminuria, the obtaining of the diazo reaction was not constant in any of the seven cases, being in evidence on one day and not on another Generally this reaction appeared to be more frequently obtained in chronic pulmonary phthisis the nearer the case was to a fatal termination, their results in this respect confirming what had been stated by Penzold, Petri and others as to the occurrence of this reaction, indicating an actively progressing stage of the disease A bacteriological examination was made of six samples of the daily secretion from each case, 200 cubic centimetres of each sample being centrifugated for 20 minutes, and cover glass specimens, six from the sediment of each 200 cubic centimetres, being stained and examined for bacillus tuberculosis In only one case was the specific bacillus found by this microscopical examination and that case was the only one in which tuberculosis of the kidney itself was found after death In 18 of the 25 cases the urine was tested by the inoculation of guinea pigs, two animals being inoculated from the sediment of one or more samples from each case The results of the inoculations were as follows Of eight fatal cases which were examined post mortem inoculation of the urine was followed by tuberculous infection in the guinea pig in six whilst of 10 cases in which the patients were still alive when last heard of the urine infected the guinea pig in three In the one case in which tubercle bacilli were found microscopically in the urine tuberculous nodules were found in the kidney after death But in this case the animal inoculations failed from early death of the guinea pigs. Thus, of 18 cases of pulmonary phthisis in which there was no reason to believe that there was any local tuberculous infection of the kidney and in eight of which post mortem examination showed that in fact there was not any, the presence of bacillus tuberculosis in the urine was proved by the inoculation of guinea pigs in nine, or just 50 per cent. At the same time the results of the animal inoculations showed that in most of the cases the bacilli were present in very small quantities indeed in some instances one out of a pair of guinea pigs inoculated from the same specimen of sediment escaping infection Also the probability of finding the bacilli by inoculation increased as the case came towards the end Other experiments bearing on the possible toxicity of the urine in these cases were carried out.

---

[1] Towards the expenses of this research a grant was made by the British Medical Association on the recommendation of the Scientific Grants Committee of the Association.

Dr C J N Longridge (London) read a paper on

Focal Necroses of the Liver

The occurrence of small areas of altered or degenerated cells in the liver in cases of typhoid fever were quoted as examples of local necrosis, the causation of the lesions by the action of toxins rather than by the direct action of the bacilli themselves was considered, and the possible relation of this focal necrosis to cirrhosis of the liver was discussed. The changes found in the liver in cases of puerperal eclampsia were then dealt with and the supposed antitoxic functions of the gland were referred to Duodenal ulceration at a point on the walls [illegible] of the bile-duct was Dr Longridge [illegible] irritation of toxins which were [illegible] These cases of focal necrosis [illegible] the action of toxins on a gland which was in the process of eliminating them. As examples of similar destruction of a tissue which was in the act of eliminating toxins Dr Longridge quoted ulceration of the intestine in albuminuria and duodenal ulceration in cases of extensive burns

In the discussion which followed the reading of Dr Longridge's paper the President (Dr J W Washbourn) said that the multiplication of bacilli in the tissues after death had perhaps led to an exaggerated idea of their influence in producing focal necrosis. He himself agreed with Dr Longridge that such lesions were more frequently the result of a general toxæmia affecting special tissues Ulceration of the large intestine in those who had taken quantities of mercury was perhaps the result of the elimination of the poison by the glands of the intestines He thought that cirrhosis of the liver might in some cases result from a fibrosis following infective neuroses

Dr W S Lazarus-Barlow (London) doubted the frequency at the present day of duodenal ulceration in cases of burns He had not himself met with such cases, but still there were undoubted specimens in museums illustrating the condition He then referred to the bacterial causation of cirrhosis and to the pathology of albuminuric ulceration of the intestine

Mr A G R Foulerton thought that the direct action of bacteria in producing these focal necroses could not be ignored in every case Such foci might be found crowded with bacteria in specimens prepared from the livers of experimental animals when the tissues had been put in alcohol immediately after death and there had been no opportunity for post-mortem multiplication of the organisms, then, too he thought that Hektoen's work on bacterial cirrhosis of the liver clearly showed that a bacterial necrosis did actually occur sometimes

Dr A S Grunbaum (London) thought that duodenal ulceration in cases of burn was due to toxins which were being eliminated; the fact that such ulceration was rarely observed at the present time was probably due to improved antiseptic treatment of such cases

Dr Longridge then replied.

Dr Lazarus Barlow read a paper on

Typhoid Fever without Intestinal Lesions

The number of cases in which typhoid fever without intestinal lesions had been recorded was exceedingly small probably not more than 20 in all and of these 20 cases the absolute scientific proof by isolation of the specific bacillus had probably not been afforded in more than six. During recent years the specific agglutination test had given them an additional method of diagnosis in these cases The case which Dr Lazarus Barlow now referred to more particularly was that of a child, aged 13 months, who died in the Westminster Hospital The patient was one of a family of seven individuals living in one house of whom six were attacked by typhoid fever All six patients including the child gave a definite Widal's reaction and the clinical symptoms of typhoid fever were generally well marked in all The patient now referred to died on the twenty fifth day of his illness His serum on the seventeenth day had given an agglutinative reaction with the typhoid bacillus with a dilution of 1 in 50 immediately and of 1 in 100 within 25 minutes. There were 'rose spots' diarrhœa, bronchitis and abdominal distension, the spleen could not be felt The post mortem examination was made within 12 hours, there were found bronchitis, broncho pneumonia, and pulmonary collapse, the spleen was firm and somewhat enlarged There was no other macroscopical evidence of disease the intestinal mucous membrane was normal in every respect From the spleen cultures of bacilli of the bacillus coli communis type and also bacillus typhosus were isolated The specific bacillus isolated was submitted to the usual culture tests and its identity was proved With the serum of a horse artificially immunised against typhoid infection the organism gave a good agglutinative reaction a dilution of 1 in 200 being used

The President referred to a case in a child under his care which had run a very similar course and in which no lesions had been found in the intestines after death, with the use of Widal's reaction such cases would now probably be more frequently diagnosed than formerly

Dr J H Bryant (London) also referred to the President's case and gave particulars as to the bacteriological diagnosis

Professor Michell Clarke (Bristol) referred to two cases of typhoid fever in which ulceration of the large intestine only was present

Dr Lazarus Barlow in his reply suggested the possibility of some of the cases of summer diarrhœa in children being really slight cases of typhoid fever

A paper by Mr A W Nuthall (Southsea) and Dr W. Hunter (London) on

The Bacteriology of Cerebro-spinal Meningitis

was read in the absence of the authors A series including 10 cases, nine in children and one in an adult, in which lumbar puncture had been performed, were examined bacteriologically. From each of these cases a diplococcus had been isolated which presented certain morphological and biological characteristics. The diplococci isolated from the 10 cases fell into two types, A and B. In the former type the staining by Gram's method was indefinite and usually negative; in type B the stain gave a positive result. There were also differences in the growth of the two types on various media used. In no case did experimental inoculation of mice, guinea-pigs, or rabbits give a positive result. The diplococcus was isolated in pure culture in four only of the 10 cases. The conclusions to which the authors had come were: (1) in 10 cases of meningitis a diplococcus was isolated from the cerebro-spinal fluid obtained by lumbar puncture during life; (2) this diplococcus agreed in its morphological and biological characteristics with the diplococcus intracellularis meningitidis of Weichselbaum; (3) the diplococcus occurred in two slightly different forms, types A and B; (4) in some cases the diplococcus was present in pure culture and in others associated with other organisms—e.g., bacillus influenzæ and bacillus tuberculosis; (5) the clinical picture and pathological changes found in these cases were those met with in posterior basal meningitis; (6) in all probability posterior basal meningitis was a sporadic form of cerebro-spinal meningitis and was caused by the same micro-organism, the diplococcus intracellularis of Weichselbaum; and (7) in the majority of the cases it was impossible from the clinical aspect alone to make a correct diagnosis of the variety of meningitis present.

The President spoke as to the confusion which existed with regard to the different types of cerebro-spinal meningitis. As regarded the pathogenicity of the organism described by Mr. Nuthall and Dr. Hunter he had himself tested the coccus which Still had isolated from cases of posterior basic meningitis and had found that it killed guinea-pigs on intraperitoneal injection.

Mr. Foulerton thought that Mr. Nuthall and Dr. Hunter had been working with two distinct species of coccus and not with merely different types of the same species. It was quite certain that diplococcus intracellularis meningitidis as described by Weichselbaum, and by Councilmann, Mallory, and Wright in their recent monograph, did not stain by Gram's method. He had found that this latter organism was uncertain in its growth on ordinary media. If it grew at all it usually grew fairly freely, but sometimes no growth would occur on one or two tubes out of a series inoculated at the same time; also the results of animal inoculation were very uncertain, some animals dying out of a series whilst others survived. He agreed that the organism described by Still in cases of posterior basic meningitis was diplococcus intracellularis meningitidis of Weichselbaum, but Dr. Hunter and Mr. Nuthall had clearly come across some other species, perhaps the pneumococcus, in their series of cases.

Dr. F. J. Poynton (London) had found great difficulty sometimes in differentiating various species of cocci. He thought that Gram's method of staining did not give constant results.

Mr. W. C. C. Pakes (London) also thought that Gram's method of staining was not always reliable. He thought that Mr. Nuthall and Dr. Hunter had been dealing with two different species, possibly the pneumococcus and the diplococcus intracellularis meningitidis.

Dr. A. Paine (London) said that his experience of Gram's method of staining as a means of differentiating organisms was not altogether favourable. He thought that the results were not always constant.

Mr. Foulerton said that he could not agree that Gram's method of staining gave inconstant results if the method was used in the proper way. The method was founded on a chemical reaction, and chemical reactions did not vary. Of course, in old cultures some of the organisms sometimes lost in a greater or less degree capacity for holding the stain which they had once possessed. But if the method was carried out as a chemical reaction should be, that was to say, with careful regard to the constant composition of the stain, and if the staining was always carried out with fresh cultures under exactly the same time and other conditions, it was absolutely reliable. Diplococcus intracellularis meningitidis was an organism which was very readily decolourised when treated by Gram's method, and he could not allow that the coccus described as type B by Mr. Nuthall and Dr. Hunter which stained by Gram's method was the organism known by that name.

Dr. Rist (Paris) spoke in favour of Gram's method of staining, which was, he thought, one of the most useful methods of bacteriological diagnosis. The positive or negative Gram reaction was absolutely constant for some species, and characteristic of them, provided that the technical details were carefully observed. There were some species which behaved inconstantly with this method of staining, but this very inconstancy was a characteristic feature of these species. Dr. Rist had been working more especially with anaerobic species, and with them had found the method most useful; he would go further and would say that in some species Gram's staining reaction was an absolutely vital reaction. For instance, in the case of the bacillus of phlegmonous emphysema described by Fraenkel if the specimen was prepared from a culture in active growth the organisms stained deeply by the method, but if a culture in which the organism had died out was used the bacilli remained absolutely unstained.

Dr. Lazarus-Barlow placed absolute reliance on Gram's method, but it must be carefully carried out and a fixed limit of time allotted to each stage of the method. In order to test the method with bacillus diphtheriæ he had recently, after staining a cover-glass specimen, irrigated it with absolute alcohol for two hours, and at the end of that time the bacilli still retained the stain. With regard to Mr. Nuthall's and Dr. Hunter's paper, his own cases showed that a meningitis precisely similar, both clinically and in the morbid changes produced, to the posterior basic meningitis described by Still could be produced by the pneumococcus; diplococcus intracellularis meningitidis of Weichselbaum was not, therefore, the only cause of this condition.

Dr. F. J. Poynton and Dr. A. Paine communicated a paper on

The Present Position of the Bacteriology of Rheumatic Fever.

The authors gave a full account of what had been done by others in connexion with the bacteriology of rheumatic fever and described the coccus which they had themselves isolated. Its pathogenic effects on rabbits were referred to and especially the production of arthritis and endocarditis with vegetations on the valves. The coccus in cases of rheumatic fever was found in the capsule of the joints affected, in the heart wall, and on the affected valves. In the history of rheumatic fever heredity took such a prominent place and the rheumatic constitution was so clearly recognised that it was hard to escape from the conviction that the disease was not to be explained by the presence and nature of the micro-organisms alone. In addition there was, they thought, to be taken into account some particular condition of the human tissues predisposing to the disease. The authors hoped that in time an antitoxin for rheumatic fever might be discovered, but their own researches at present pointed to the fact that the diplococcus was widely distributed throughout the body, and not confined to one spot, as was usually the case in, for instance, diphtheria. At the end of the paper lantern slides illustrating the pathology of rheumatic fever were shown, and Dr. Paine demonstrated the joint and valve lesions which they had been able to produce in rabbits.

The President commented on the value of Dr. Poynton's and Dr. Paine's work. He assumed that an absolute diagnosis of rheumatic fever had been arrived at clinically in all the human cases. He raised this question because of the large number of cases which Dr. Poynton and Dr. Paine had been able to examine post mortem; his own experience was that rheumatic fever was now very much less fatal than in former times.

Mr. Foulerton asked in what proportion of the cases vegetations had been found on the valves in the rabbits inoculated. Shortly after the first appearance of Dr. Poynton's and Dr. Paine's work the hearts of all rabbits killed or dying in his own laboratory had been examined, and they had been much struck by the fact that two out of the first nine animals examined showed well-marked vegetations on the left heart valve. It was evident that such lesions occurred in rabbits quite independently of inoculation with this coccus. Mr. Foulerton did not think that Achalme's conclusions were of any value; the bacillus which Achalme had isolated from cases of rheumatic fever was probably bacillus enteritidis sporogenes of Klein, and it was most improbable that it had any causative influence in the disease. He also asked whether Dr. Poynton and Dr. Paine had been able to immunise rabbits against infection by their coccus. Rheumatic fever was a disease in which a previous attack seemed to predispose to another rather than to confer any immunity. That being so the effect of the attempted immunisation of rabbits might be interesting.

Dr RIST said that since the appearance of Achalme's paper it had been shown that the bacillus which he had described was very frequently to be found in a number of cases, pathological or not in which rheumatic fever was out of the question The spores of this bacillus were to be found in milk which, not having been thoroughly sterilised, had been incubated anaerobically, and it might be that from this source Achalme's bacillus had come In describing for the first time an organism for a disease which like rheumatic fever, was so common, and the bacteriology of which had been investigated by so many competent pathologists, it was most necessary to explain why previous workers had failed to find the organism. In the case of tuberculosis the failure of others before Koch to find the bacillus was quite easily explained by what they now knew of the difficulty in staining the bacillus and in growing it on artificial media. These difficulties did not exist in the case of the diplococcus which Dr Poynton and Dr Paine had described for rheumatic fever, and he would like to ask if any explanation of the failure of other bacteriologists to find it could be given

Dr HARRY CAMPBELL (London) asked whether the diplococcus had any special affinity for the red corpuscles of the blood and whether one could account for the anæmia which was so characteristic of rheumatic fever by assuming that the chromocytes were actually destroyed by the organisms He also asked whether the experimental endocarditis produced in rabbits attacked the left side of the heart more frequently than the right, as in man

Mr T J BOKENHAM (London) could confirm what Mr Foulerton had said as to the occurrence of vegetations on the heart valves in rabbits When investigating the action of streptococcic toxins on rabbits Mr Bokenham had carefully examined the heart in a large number of cases and had found vegetations on the valves in about one animal in 10

Dr POYNTON in replying, said that they had met with Achalme's bacillus in the course of their work, but they thought that it had no connexion with the disease After some early experiences they had always incubated their milk tubes anaerobically over night before inoculating them in order to ensure the use of only sterile ones One reason perhaps, why previous workers had not found the diplococcus was that the organism was found chiefly in the capsule in joint affections and not in the effusion which was what the majority had worked with No special affinity of the diplococcus for the red blood cells had been noticed No definite success in the immunisation of rabbits had yet been obtained All the human cases in which the coccus had been found were cases which had been diagnosed as rheumatic by the various physicians in charge of them

Dr G H GOLDSMITH (Bedford) read a paper on

The Hæmoglobin Value of the Red Blood Corpuscle

The amount of hæmoglobin in the blood might be estimated quantitatively by several methods (1) chemically, (2) by spectrometry, and (3) by colorimetric analysis, and the various objections against any one of the methods by itself were considered The method which Dr Goldsmith had employed included (1) the estimation of the hæmoglobin value of the blood by Gowers's hæmoglobinometer (2) the corpuscular count with the Thoma Zeiss apparatus, (3) the estimation of the percentage of corpuscles to plasma, (4) the count of the precipitated corpuscles, and (5) the estimation of the hæmoglobin value of the corpuscles Having described his methods in detail Dr Goldsmith gave the result of his examination of the blood in 18 males and 15 females, all healthy subjects The hæmoglobin value of the blood was 117 in men and 105 in women, taking 117 as 100 the respective values for the two sexes were 100 and 89 7 figures which closely corresponded with Dr Haldane's 100 and 89 for the male and female. With regard to the red cell count the figures which he had obtained were an average of 4 860 000 per cubic millimetre for the healthy male and 4 350 000 for the healthy female The average relation of corpuscles to plasma by bulk was 37 per cent for the healthy male and 30·25 per cent for the healthy female The count of the precipitated corpuscles, even in healthy people varied, however, enormously from time to time His investigations had shown that the male had a larger number of red cells than the female, whilst the hæmoglobin value of the corpuscles was less in the female than in the male and the size of the individual corpuscles rather smaller

The PRESIDENT paid a compliment to the thorough way in which Dr Goldsmith's work had been carried out, and Dr LAZARUS-BARLOW pointed out the great difficulties which had to be overcome before accurate quantitative blood work could be done He also spoke of the value and clinical importance of similar work in connexion with cases of anæmia in which Dr Goldsmith was now engaged

---

OPHTHALMOLOGY

FRIDAY, AUGUST 2ND

The Varieties and Treatment of After cataract

This discussion was opened by Mr RICHARDSON CROSS (Bristol) who said that there were no known means by which after cataract could be absolutely prevented. He did not advise any early secondary operation as it was uncertain how much absorption would take place and the eye should be allowed to quiet down completely For ordinary cases a modified Bowman's needle with a cutting edge should be employed and if this failed a second cutting needle should be entered at the same aperture in the capsule In complicated cases capsule scissors should be used A form of iridectomy scissors had been made on De Wecker's plan, but with blades having double cutting edges These could be used closed as a keratome and as scissors when opened within the eye A still thicker capsule should be extracted, but only as a last resort

The PRESIDENT (Mr W H H JESSOP, London) considered a very sharp and ground down Graefe's knife far better than a needle and he thought that a simple extraction without iridectomy was less liable to be followed by secondary cataract

Dr DARIER (Paris) thought that the one thing to be avoided was penetrating deeply into the vitreous

Mr HENRY POWER (London) described various methods of proceeding and thought that the danger of operating in these cases was very great and should only be incurred when the vision was very defective

Mr DEVEREUX MARSHALL (London) was fully convinced of the danger of needling and he avoided it whenever he could, but he thought that when it was inevitable it should be done early

Dr LATHAM THOMPSON (Cardiff) Mr DYKES BOWER [illegible] PSON (London) Mr G W [illegible] CHILL (London) and Mr G [illegible]

Mr RICHARDSON CROSS in reply said that in simple extraction he thought it far more important thoroughly to replace the iris than completely to remove all lens matter He thought that if no iridectomy were done the liability to glaucoma was far less—in fact he had never had a case He thought that the needle described by Dr Darier was a very good one Sepsis was not accountable for all the cases that did badly He always inserted the needle peripherally All cases should be treated on their own merits and there was no fixed rule as to what state of vision justified needling

Dr F W EDRIDGE GREEN (London) read a paper on

The Essentials of a Test for Colour blindness

He strongly advocated the use of names when trying and mentioned the fact that many normal sighted persons were rejected by Holmgren's test and also that varieties of colour blind people could pass that test

Mr DEVEREUX MARSHALL agreed with Dr Edridge Green's conclusions, having arrived at similar results from his own experience

Mr G HARTRIDGE read a paper on

The Various Preparations of Silver used in Ophthalmic Work

Nitrate of silver should only be applied by skilled hands on account of its liability to injure the cornea; the caustic effect might cause sloughing and cicatrices and also a deposit of silver in the tissue Among the new preparations he mentioned actol the lactate which he found to be of no use and itrol the citrate Argentarium containing a very small percentage of silver was of no particular value Nargol with 10 per cent of silver possessed many of the properties of protargol It was less sticky and produced no pain and was of service in conjunctivitis and lacrymal cases Largin contained 11 8 per cent of silver the highest percentage in use It was uncertain in its effect on purulent ophthalmia and useless in chronic cases but useful in trachoma and lacrymal cases in 10 per cent solution Protargol was one of the best known preparations containing 8 3 per cent of silver A 1 per cent. solution was equivalent to 2 per cent. of nitrate of silver and possessed greater penetrating power; there was no caustic effect and it induced no pain. He used 10, 20, and 30 per cent. solutions—the last twice in 24 hours for purulent ophthalmia. It possessed great germicidal power. For trachoma he used a 50 per cent. solution.

Dr. **Darier** thought that in many cases silver nitrate had a very bad effect. In feeble children a 2 per cent. solution might do much harm and possibly might cause ulceration of the cornea. He preferred the constant application of a drop of 5 per cent. protargol in ophthalmia neonatorum. After a few days the conjunctiva became tolerant and then silver nitrate solution could be used. In blepharitis he approved of 30 per cent. solution of protargal.

Dr. J. A. **Bower** (Cheltenham) read a paper on

The Use of Suprarenal Gland in Ophthalmology,

which proved very satisfactory when prepared by macerating the fresh gland and combining it with chloretone for preserving purposes. It was of great value in hay-fever with conjunctival irritation, both as a nasal spray and as a local application. From 12 grains to one drachm was the strength used. In corneal ulceration it was harmful.

Dr. **Darier** read a paper on

The Latest Therapeutical Discoveries in Ophthalmology—Acoine, Dionine, Epinephrine, &c.

Of the silver salts protargol was the most reliable, though ten times weaker than silver nitrate. For subconjunctival injections acoine was painless and without local action, but a prompt anæsthetic. Dionine was effectual in iritis when atropine failed to dilate the pupil alone. It was also an antiseptic and analgesic, and acted powerfully in the deep-seated pain which cocaine failed to relieve and in that of acute glaucoma and iritis.

Mr. F. M. **Granger** (Chester) thought that no one could deny the great power of suprarenal capsule. Jacques's solution was the best and contained both a contracting and dilating substance. Dionine was a very useful drug for diagnostic purposes.

Dr. E. E. **Maddox** (Bournemouth) agreed. He was struck with the value of suprarenal extract in preventing hæmorrhage in excision of the eye.

Mr. **Sydney Stephenson** (London) and Dr. **George Carpenter** (London) read a

Note upon Tuberculosis of the Choroid,

illustrated by ophthalmic pictures and microscopical specimens. White spots were seen in acute miliary tubercle, in multiple lesions two or three, less frequently there was one larger mass at the macula. In chronic tuberculosis the lesions might be single or multiple, and sometimes so diffuse as to resemble a neoplasm. Occasionally the deposit disappereed.

The **President** spoke of one such case as that last mentioned.

Mr. H. E. **Jones** (Liverpool) read his motion concerning the compensation of workmen after eye injuries, which was seconded by Mr. **Henry Power**.

On the motion of Mr. **Cargill**, seconded by Mr. **Stephenson**, this was referred to a committee.

DISEASES OF CHILDREN.

Friday, August 2nd.

This section began work (all its officials being present) with an admirably clear and succinct paper by Mr. H. J. **Stiles** (Edinburgh) on

The Radical Cure of Hernia in Infants and Young Children.

This was based on his own experience of 100 cases. He referred to the discussion in the section on the same subject at the Portsmouth meeting when it appeared to be the general opinion that there were practically no risks in these operations, no recurrence (as a general rule), and no apparatus needed afterwards. He did not agree with the opinion that a young child had not the necessary development of the parts about the internal and external ring for operation. and he considered that infants bore operation very well. The operation consisted in isolating and removing the funicular process and in introducing one or two sutures to reduce the size of the ring and to lessen the liability to hernia in after-life. These herniæ were chiefly right-sided. Nineteen were present at birth, and 83 per cent. appeared in the first year of life. Out of 78 patients 72 did not have the sac communicatin with the processus vaginalis. The steps of the operatio were three—to expose the cord and its coverings, to excis and to ligature the process, and to suture the ring and to clos the wound. After referring to the isolation of the sac h said that where this was thin and transparent he though it unnecessary to open the sac, as the contents could be see and felt through the covering. Where, however, a truss ha been worn the sac might be considerably thickened, and i would be wise to open the sac so as to be sure tha the bowel had been all returned. He exhibited the needl which he used for suturing the ring, which he did wit sterilised catgut. In 86 cases the hernia was easil reducible. In seven cases it was irreducible, but o these four were spontaneously reduced. In one cas evidently the bowel had got much bruised by taxis applie before the child was admitted. It was therefore wise t wait (unless, of course, any urgent symptoms were present and to see if any irritation was likely to come from taxi where that had been tried. Strangulation had taken plac chiefly in infants, but it was quite a different thing from tha in adults as it was a very gradual process. In four cases th appendix was removed; in three cases the sac was found t be tuberculous, and under the anæsthetic the mesenter glands were felt to to be enlarged. Two cases only ha recurred; one where the bowel was strangulated and on a case of hypospadias. There were three deaths—one as mentioned above, where the bowel was much bruised b the taxis; a second 36 hours after the operation (no caus could be found post mortem, but there was an epidemic o influenza at the time); and a third with acute jaundice an suppression of urine on the third day, probably due t chloroform poisoning.

Mr. W. **McAdam Eccles** (London) dealt with the cause of hernia. Besides the anatomical cause he considered ba feeding (as was insisted upon in Wednesday's discussion o Intussusception) and pulmonary disease, whooping-cough and bronchitis especially as great causes of hernia in children. The relation of phimosis to hernia had been discussed at th Portsmouth meeting, where it was pronounced to be better no to operate in the first year of life (if no urgent reason wa present for so doing). What were they to do with the chil in the meanwhile? A properly made and fitted truss shoul be worn during the first year; it would frequently cure the hernia (more than half the cases were so cured), or at all events would prevent the enlargement of the rupture, which was sure to happen if no truss was worn. The truss should be covered with black rubber (red rubber was very apt to excoriate the skin) and if properly put on would keep in its place. He had two objections to the use of sutures for the mouth of the sac—that they seemed to interfere with the valve-like action of the lower fibres of the ring and that when sutures were introduced there appeared to be a little more tendency to suppuration. When suppuration had occurred sometimes adhesion of scar and intestine took place. He would always open the sac; occasionally a bit of omentum might be left in it, and once he had found a projecting portion of the bladder therein. He preferred silk for tying the sac In cases of cæcal hernia he always removed the appendix. He suggested that cases of tuberculous sac might be due to tubercle of the peritoneum. He sutured the wound very closely and covered it with collodion dressing. He kept the children in bed for about 10 days. He agreed with Dr Stiles that infants and children were operated on with great success.

Mr. C. F. **Cuthbert** (Gloucester) discussed several points of the paper and made the useful suggestion (which he himself always adopted) of keeping the child bandaged up (exactly as would be done afterwards) for a few days *before* the operation.

Dr. E. **Mansel Sympson** (Lincoln) always had the phimosis which so frequently accompanied hernia in infants operated on at once. This often (with, no doubt, the rest in bed and proper dieting) caused the hernia to disappear or, at all events, lessened it.

Dr. **Ferguson** (Chicago) did not operate in these cases (unless the hernia was very large or strangulated) until the child began to walk, till which time a truss was worn. He attributed part of the causation of hernia, more especially in males, to a deficiency of the region of the internal oblique muscle from Poupart's ligament. In females this came more from the middle and inner portion of the ligament; in males chiefly from the outer half. The internal oblique should be the the natural guardian of the internal ring.

So, after having operated, he brought the attachment of the muscle down to the middle of Poupart's ligament and united it with the ligament." This part of the operation he explained on the blackboard. He was questioned as to any recurrence, and he mentioned that he offered 10 dollars for any case of recurrence; years had gone by, but he hadn't had to pay. One patient came back, but the rupture was on the opposite side.

The PRESIDENT (Mr FREDERIC EVE) considered that Mr. Stiles's practical paper would have a great influence on surgeons in this country who, like most of them, were impressed with British statistics. He agreed with all the important points in the paper. He would never hesitate to operate on a child under one year of age if the hernia was large. He usually slit up the aponeurosis of the external oblique so as to tie up the sac as high up as possible. He did use kangaroo tendon, but now he preferred silk. He agreed that recurrence took place only in cases wherein strangulation had occurred previously to operation originally.

Mr. STILES considered that pulmonary trouble was among the chief causes of hernia, as mentioned by Mr. Eccles. He thought that worsted trusses were absolutely unsatisfactory. His objection to silk was that if the wound did become septic it made the condition of the wound so much worse. There was not nearly so much risk of this if catgut was used. He found that the temperature in his cases was lowered since he had abandoned the use of antiseptics and only used sterilised dressings. He had generally found that there was rather a redundancy of the internal oblique than any deficiency.

Dr. WILLIAM EWART (London) then read a paper by himself and Dr. W. LEE DICKINSON (London) on

Two Cases of Chronic Hydrocephalus in Infants treated by Tapping and the Introduction of Aseptic Air in the Place of the Fluid.

He described the method of operating, two Southey's tubes with rubber continuations being introduced into the ventricle a little distance apart, the end of one being passed into an antiseptic solution and the end of the second fitting on the nozzle of a glass syringe devoid of its piston which after sterilisation had its mouth plugged with sterilised wool. The tubes were allowed to stay in for various lengths of time, from seven hours to two days, and varying quantities of fluid escaped, from 18 to 50 ounces, its specific gravity, low at first (1004) increasing after the first two or three tappings to about 1011. The first case treated improved in several points, the hydrocephalic cry altered in character, and the pressure symptoms were relieved. In the second case the tubes were left in for nine hours, and six and a half ounces were removed. The screaming stopped and the fluid did not re-accumulate. These cases showed that the fluid might be [illegible] air properly filtered might take [illegible] might suffice, and that in cases [illegible] ssure on the brain was much relieved.

The paper was discussed by Dr. G. ERIC PRITCHARD (London), Mr. ECCLES, and Mr. STILES, and Dr. EWART briefly replied.

Dr. F. E. BATTEN (London) then contributed a paper on

Suppurative Pericarditis in Children.

He commented on six cases in patients of various ages, from 10 months to three years. In two cases it commenced after measles and in the rest after bronchitis or pneumonia. There was no very definite feature in the temperature. The pulse was rapid, from 150 to 160 per minute, with surprisingly little distress. There were in some cases œdema of the legs and feet and attacks of cyanosis. The impulse-beat was in the ordinary position, or epigastric. There was no heart murmur or pericardial friction. There were marked physical signs in the lungs of consolidation or pleural effusion. Both pleuræ were adherent in all the cases, with some fluid, and in one dried-up pus. In one case there was evidence of tubercle. Inside the pericardium there were from a few drachms to six ounces of pus. There was no endocarditis. One patient had tuberculous peritonitis and another had tuberculous meningitis. The condition of these cases was very like that of children suffering from empyema. As to treatment it would be better not to use an exploring needle, but to open an intercostal space or to resect a rib to get at the pericardium.

Dr. MANSEL SYMPSON then exhibited the stone (weighing 200 grains) and read the notes of a case of

Suprapubic Lithotomy

in a boy 11 years of age. The symptoms had lasted about five years, there being pain before and during micturition which was of great frequency, especially at night. On Oct. 30th, 1900, the bladder having been sounded five days before and a stone having been found, suprapubic lithotomy was performed. The stone, which was two inches long by half an inch thick, was extracted and the bladder opening was sutured (the mucous coat being avoided). This was done as the bladder was so small, the skin wound being left *open at the lower end with a gauze drain. The after-history* was quite uneventful, and the patient was discharged cured on Dec. 3rd.

Dr. PRITCHARD then read an exhaustive and valuable paper on the Over-feeding of Infants, which was afterwards discussed by Dr. H. CAMPBELL (London).

Papers by Dr. G. F. STILL (London) on Suppurative Pericarditis in Children and by Dr. A. H. BAMPTON (Ilkley) on Mumps associated with Endocarditis were taken as read.

Dr. A. G. FOLJAMBE FORSTER (Cheltenham) then showed a temperature chart of Acute Pneumonia with Hyperpyrexia treated with oxygen from the first, to which he considered the child owed its life; a well-marked case of Pseudo-hypotrophic Paralysis; a very interesting case of Transposition of the Heart to the Right (the apex beat being at the right nipple) from Right-sided Empyema; and a case of Diplegia following an attack of convulsive fits, measles, pneumonia, and meningitis.

LARYNGOLOGY AND OTOLOGY.

FRIDAY, AUGUST 2ND.

Dr. WATSON WILLIAMS (Bristol) gave a lantern demonstration with stereoscopic slides of Anatomical Preparations of the Naso-pharynx and Larynx. He illustrated the remarkably realistic effects that could be obtained by this method and its value for purposes of teaching and demonstrations.

Dr. HEMINGTON PEGLER (London) read a paper on

Morcellement of the Tonsils.

Instruments used in the operation were shown. The operation was suitable for cases which could not be dealt with in the ordinary way by the tonsillotome and could be performed under a local anæsthetic.

In the discussion which followed

Dr. BROWN KELLY (Glasgow) spoke in favour of cocaine or eucaine in a solution of rectified spirit and aniline oil, as recommended by Dr. A. Gray, as an efficient local anæsthetic for the operation.

Dr. JOBSON HORNE (London) inquired whether Dr. Kelly in his experience *had met with the untoward symptoms* described by some who had used cocaine and eucaine mixed with aniline oil

Dr. BROWN KELLY said that he had observed cyanosis following the use of this anæsthetic, but he had not met with the alarming symptoms that others had described.

Dr. HERBERT TILLEY (London) considered the operation that had been *described under the term "morcellement"* was suitable only for the removal of long, flat tonsils and was not intended for cases suitable for the guillotine.

Mr. G. P. FIELD (London) read the notes of the following cases of

Aural Disease from South Africa.

Case 1.—*Lieutenant* —— was wounded in the Boer war by a splinter of shell which had passed through the antrum and palate; he had sustained injury to the right membrana tympani from the same cause The cure of the otorrhœa and the healing of the membrane resulted in the restoration of hearing. Case 2.—A trooper, a New Zealander, sought advice on account of double perforation due to combined starvation and exposure at nights during the Boer war. *He was cured by* application of a 10 per cent solution of trichloracetic acid. Case 3.—The patient, another sufferer from the war, was kicked on the right side of the head by a stampeding horse. The result was incurable deafness of the left ear, probably from damage to the labyrinth Case 4.—A major became deaf from concussion of heavy guns The treatment was as follows: rest to the ear, counter-irritation over the mastoids, and iodide of potassium internally. Nearly complete recovery was the result. Cases 5 and 6 were instance of chronic non-suppurative catarrh and polypus respectively from a prolonged exposure to cold rainy weather in Zululand Successful treatment was carried out after the lapse of three years. Case 7.—The patient suffered from absolute deafness with tinnitus and giddiness developed about nine months after contraction of syphilis. Treatment consisted of hypodermic injection of one-eighth grain doses of pilocarpin. The result was negative at first, but eventually complete restoration of hearing of the left ear and general improvement in health followed. Cases 8 to 12 —Aural exostoses. These, in the speaker's experience, were best treated by making a small opening with the dentist's drill. A sequence of cases afforded confirmation of Mr. Field's original opinion as to the frequent causation of exostoses by persistent sea-bathing. In one instance, at least, double exostoses appeared to have originated in irritation due to the use of the binaural stethoscope. Case 10 afforded an example of the risk of formation of abscess attendant on delay in operation. Case 12 was an instance of the comparatively soft exostoses met with chiefly in women. A main feature in all these cases was the good results accruing from the drilling of an opening of small calibre through the apices of the ivory exostoses.

Dr. Herbert Tilley reported a case of

Chronic Mastoid Antrum Suppuration Complicated by Aural Exostosis.

The patient was a female, aged 65 years, and the suppuration had lasted for 40 years. The supervention of pain in and around the right ear with paralysis of the face on the same side necessitated the complete mastoid operation. The meatus was so narrowed that it would not admit the finest probe. The interest of the case lay in the fact that in spite of a large portion of the concha and posterior meatal wall having been removed at the operation the meatus had contracted since the operation so that only an ordinary surgical probe could be passed through it. Ballance had suggested that such post-operative atresia might be prevented by skin-grafting, but the patient being a great sufferer from angina pectoris it was thought unwise to suggest such a course in her case, as she remained very comfortable and the power over the facial muscles was returning nearly five months after the operation.

Dr. Dundas Grant (London) communicated a paper on

Some Details in Eustachian Catheterisation.

A difficulty which had baffled an operator was the steering of the catheter past some deformity of the septum, whether a deflection or thickening. Generally the obstruction had been a ridge running obliquely upwards and backwards, sometimes a so-called scoliosis bulging low down in front. Discomfort and disappointment had resulted from a preliminary rhinoscopic examination not having been made. The application of a weak solution of cocaine facilitated catheterisation by diminishing the patient's sensitiveness and reducing vascular turgescence of the mucous membrane. The passage of the catheter was also facilitated by the use of the speculum at the same time. In the case of an oblique ascending ridge on the side of the septum it might be taken, as a general rule, that the catheter should be introduced with its beak pointing towards the septum and underneath the ridge, that when it was in this way pushed back as far as it would go the point should be turned downwards and outwards underneath the inferior turbinated body and upwards into the hollow, and then upwards and outwards into the vault of the inferior meatus. It was sometimes necessary to withdraw the catheter slightly before engaging its point under the inferior turbinal. The instrument was then pushed steadily backwards until it was felt to be free in the naso-pharynx, when it could be turned downwards and hooked over the back of the soft palate; in some cases where the septal ridge diminished rapidly and considerably towards the posterior part the beak of the catheter need not be turned under the turbinal at all but kept pointing upwards under the septal crest until the naso-pharynx was reached. This proceeding was greatly facilitated if the point of the nose was pressed forcibly upwards. When the inferior turbinal projected considerably and the septal spur was not very great it was sometimes advantageous to pass the catheter above the turbinal till its tip pointing downwards reached the naso-pharynx, when by a little steady downward pressure the stem of the catheter might be forced down between the turbinal and the crest on to the floor of the meatus. In another class of case there was a projection from the septum at the junction of its posterior and middle third presenting a somewhat arched slope on inspection. When this was present the passage of a sufficiently curved catheter was quite impossible as long as the usual rule was followed of turning the beak downwards and pushing it along the floor of the nose. The catheter must, on the other hand, be placed with the back of its beak on the floor of the nose after the manner of the head of a golf club, and to allow this position to be maintained whil the catheter was pushed sufficiently far back for its tip to ge in the arch-like projection it was necessary for the tip o the nose to be tilted upwards and to the opposite side.

TROPICAL DISEASES.

Friday, August 2nd.

The Honorary Secretary (Dr. Max F. Simon, C.M.G was in the chair.

Lieutenant-Colonel A. Crombie, I.M.S. (retired), read paper on

The Maladies of European Children in Hot Climates.

He stated that, speaking generally, it might be said that th sick-rate of European children was lower in India than it wa in the United Kingdom, but that, on the other hand, whe they came to speak of the death-rate the matter took a altogether different complexion, and the illnesses o European children were more frequently fatal in India tha were those of children at home. From a table, showing th sick- and death-rates as well as the case mortality of th principal diseases affecting children in India and the Unite Kingdom respectively in 1899, it appeared that when on deducted, from the 2899 admissions among the 550 European children in India, the 535 cases of malarial feve which were not common to both countries, the admission-rat in India was reduced to 429·8 per 1000, or just about 100 pe 1000 less than it was in the United Kingdom; so tha if these children could be defended from the bite of th anopheles mosquito their chances of illness would be 10 pe cent. better in India than in the United Kingdom. Th diseases referred to by Lieutenant-Colonel Crombie wer eruptive fevers, malarial and other fevers, tuberculo diseases, debility, and other general diseases—of th nervous system, of the respiratory system, and of th digestive system. It was surprising to note that, as matter of fact, at least among soldiers and their children, diseases of the digestive system were rather more prevalent at home than in India, but it was noticeable that, as Lieutenant-Colonel Crombie remarked: "It is not their frequency but their mortality that constitutes their gravity." The mortality from these diseases was just four times greater in India than it was at home among children, and nearly six times greater among adults. Liver abscess was entirely absent after dysentery in children; this was no doubt explainable by the kind of dysentery from which children suffered. Dysentery was frequently confounded with rectal catarrh or proctitis of a transient character, and it was in these cases that ipecacuanha and the saline treatment had acquired a reputation which it was doubtful if they deserved, as in cases of the kind the patient tended to recover without specific remedies. Concerning the diagnostic value of the Widal reaction Lieutenant-Colonel Crombie remarked: "I think it will be found that a very large percentage of natives of India who are not suffering from any febrile condition and who have never, or certainly not for many years, suffered from any fever which could be by any possibility diagnosed as enteric fever, give the reactions in a perfectly characteristic way." As regarded tuberculous diseases Lieutenant-Colonel Crombie stated that while the admission rate for all tuberculous diseases appeared to be higher among European children in India, the death-rate and case mortality were both lower. These numbers might, however, be affected by the habit of invaliding to England.

Dr. Edward Henderson (Shanghai) insisted upon the advantages of obtaining a wet nurse instead of bringing up children by the bottle when the mother could not nurse her child in warm climates. European children should not be kept in the tropics after from four to seven years of age. If they were kept longer they were apt to become anæmic, to have attacks of digestive disorders, diarrhœa, and dysentery, and they were apt to grow too rapidly for their physical strength.

Dr. Patrick Manson, F.R.S. (London), believed that many diseases were included under the term "dysentery" and that a definition of the term was a pressing necessity. He noted that Lieutenant-Colonel Crombie took no notice of such diseases as diphtheria, trismus neonatorum, or hypertrophic cirrhosis of the liver in children.

Major W. H. Burke, I.M.S., considered the rainy season most insalubrious in Bombay. He endorsed Lieutenant-Colonel Crombie's opinion concerning the prevalence of enteric fever and said that tuberculous ailments amongst European children were frequent.

Mr. J. CANTLIE stated that in Hong-Kong from 1887 to 1896 trismus was responsible for 50 per cent. of the total mortality in the island. He had known trismus to be conveyed to a European infant by a European nurse who came from a convent where trismus was very prevalent. Half caste persons in Hong-Kong suffered more from phthisis than either the Europeans or the Chinese.

Mr. JOHN D. GIMLETTE (Pahang) read a paper on

An Epidemic of Zinc Poisoning through Drinking Contaminated Water in the Tropics.

He stated that the epidemic occurred during 1900, among a half company of men of the Malay States Guides (Sikhs and Pathans) stationed at Kuala Lipis, Pahang. The men lived in barracks, which were built in 1898, and were roofed with galvanised iron. In January, 1900, galvanised iron tanks were supplied in order that water might be collected from the roofs of the buildings, the water-supply having been obtained previously from a large river in the neighbourhood. In 1900 an unusually large number of men were attacked with gastro-intestinal troubles and at the close of the year it was found that 43 individuals out of the 66 men of the half company had suffered. Mr. Gimlette began to suspect some form of metallic poisoning and sent samples of water to the Government analyst in Singapore, who reported acid carbonate of zinc in solution in large quantities, from 5·82 to 11·45 parts per 1,000,000. Discontinuance of the water was ordered and the number of gastro-intestinal patients steadily decreased, only 22 cases (many of these being old patients) having been treated from January until April, 1901. The symptoms presented were those of colic, diarrhœa with consequent anæmia and emaciations, and a spurious kind of dysentery. A clinical account of six typical cases, [illegible] continued diarrhœa [illegible]

Mr. Gimlette asked [illegible] not advisable that inquiry should be made as to possible contamination of water in places in Australia and South Africa where water was collected from galvanised iron roofs, especially in regard to the prevalence of gastro-intestinal disease in the latter country.

Dr. MANSON, Dr. M. F. SIMON, Dr. E. HENDERSON, and Mr. J. CANTLIE joined in the discussion upon the relation of beri-beri to metallic poisoning and all concurred in negativing the assumption.

Dr. J. PRESTON MAXWELL read a paper upon

Filarial Abscess.

He stated that in his practice in Southern China he was struck with the frequent occurrence of abscess in connexion with the scrotum as compared with its occurrence in England. In searching for the cause he commenced to examine the blood systematically. He found filaria sanguinis hominis nocturna in all cases. Such abscesses occurred most frequently in the scrotum, but they might occur also in any situation where there was loose connective tissue rich in lymphatics. In one case only were portions of the body of a parent worm found in the abscess. The death of the parent worm might sometimes be the cause of the abscess, but Dr. Maxwell was inclined to think that in many cases the cause might be connected in some way with the blocking of lymphatic vessels, especially as in some cases the abscess appeared to be the first manifestation of elephantoid disease of the scrotum or of a limb. Filarial abscess might be thus classified: (1) abscess of the scrotum—(*a*) suppurating hydrocele, (*b*) abscess of the cord, and (*c*) abscess below the testicle; (2) abscess of the limbs; and (3) intra-abdominal or intra-thoracic abscess. Filarial abscess, if treated, ended in recovery so far [illegible] concerned, but it was liable to be [illegible] ouble, of which, as had been said [illegible] the first manifestation.

Dr. MANSON said that filarial abscesses developed either in connexion with dead parent filariæ or in obstructed lymphatics. Grave conditions arose from the death of a parent filaria in the lymphatic channels of the thorax. He remarked on the disappearance of filarial embryos in the blood subsequently to the development of such abscesses in the abdomen. He considered that removal of the groin glands in filarial disease undertaken for the purposes of cure by removing parent filariæ was scarcely a rational method of treatment, as parent worms existed in numbers in the lymphatics elsewhere in the body. He advised short-circuiting the obstructed lymphatic circulation in such cases by stitching a lymphatic in the thigh to a venous trunk, so that the blocked channel might get relief by discharging its contents into the venous circulation.

Professor J. A. MACWILLIAM (Aberdeen) saw no physiological reason against the lymphatic current being directed into a vein in such a region as the groin.

Dr. W. GILMORE ELLIS (Singapore) read a paper entitled,

Some Remarks on Asylum Practice in Singapore.

He remarked that as in India, so in the Straits, the majority of patients belonged to the lowest classes. There was a marked absence of the more acute forms of insanity, the most prevalent form being an exaggeration of a low standard of intelligence passing rapidly into dementia. Primary dementia was not uncommon. Delusions and hallucinations were, as a rule, of a very simple character. A belief in witchcraft was universal. Melancholia was rare and never very acute. General paralysis of the insane was rarely, if ever, seen among Asiatics. The general causes of this disease—anxiety, worries, excesses—were uncommon among Asiatics. The female recovery-rate was about 35 per cent., while that for males was about 41 per cent. There was no puerperal insanity; Dr. Ellis had seen only one case in 12 years, and this possibly partly accounted for the low female recovery-rate. Insanity consequent upon syphilis or following malarial fever was common; the latter ended in recovery. Neither opium-smoking nor the subcutaneous use of morphine was a cause of insanity. The food question in an Eastern asylum was important, and refusal of food must not be looked upon as a sign of insanity without careful investigation, as, so long as a mere glimmering of sense was left to the patient, such refusal might be a question of "caste" or religious prejudice. There was great difficulty in finding amusements for Asiatic patients. Dr. Ellis stated that beri-beri was a large cause of mortality in the lunatic asylum of Singapore. He concluded his paper with a few [illegible] e conditions under which [illegible] this mental condition to [illegible]

Some Points connected with Human Filariasis.

Dr. J. EVERETT DUTTON (Liverpool School of Tropical Medicine) described a "weak spot" in the labium of the mosquito as the aperture of exit of the filarial parasite whilst the mosquito was feeding. Grassi believed that whilst the mosquito was feeding the bent condition of the labium was such that it gave way and allowed the embryo to escape. Dr. Dutton, however, found that the chitinous condition of the labium near the top was replaced by a delicate membrane and that it was at this point that the parasite in all probability escaped. As regards the food of anopheles, although Dr. Manson had stated that the labium had been found still occupied by filaria after many meals of bananas, yet Grassi and Noe had found the labium empty, and in all probability the filaria did occasionally pass into fruits and vegetables.

Dr. MANSON remarked that Dr. Dutton's observation was a very [illegible] of filarial infection, and th[illegible] nd intricate subject of how [illegible] the mosquito to the human body.

NAVY, ARMY, AND AMBULANCE.

FRIDAY, AUGUST 2ND.

Mr. J. CANTLIE, opened the proceedings of this section with a paper on

Medical Cadet Corps.

He advocated the including of the medical student in a military medical cadet corps as early as possible in his career when his mind was not yet made up as to his future career and thus to catch him before he became imbued with the prevalent abuse of the services by newspapers. He thought that the medical profession ought to make some return to the State for the benefits which they derived from its protection. He would have a medical cadet corps at every medical centre for teaching and thus overcome the objection of centralising and taking men away from their work. They could be trained in ambulance work and could take their name from their school, as "Cambridge Medical Cadet Corps," "Edinburgh Medical Cadet Corps." They should have a special uniform and adequate grants for efficiency should be given. Nominations should be made to the army and navy only from those who had gone through the medical cadet corps at their school. Promotions in the corps should be by State examination. Preference should always be given to old cadet corps students. Medical students should not be allowed to serve as privates along with laymen. This would increase the prestige of the medical men in the service, to which they were as much entitled as were cadets of engineers or artillery.

The PRESIDENT (Deputy Surgeon-General W. G. DON) made commendatory remarks on the paper and invited discussion.

Surgeon-General T. F. O'DWYER, A.M.S., thought that more detail of expense of forming medical cadet corps was wanted before the matter could be gone into. He preferred that commissions in the Royal Army Medical Corps should be granted after competition and not on nominations. One difficulty about cadet corps was that there were no volunteers in Ireland. How could that be got over? The response of volunteer medical officers to his inquiries as to their willingness to go to South Africa was not very satisfactory. If the Government could not support a medical cadet corps the schools might refuse the expense themselves.

Surgeon-General C. M. CUFFE, C.B., did not approve of volunteer cadet corps as units except in order to accustom medical students to the work. A large number of volunteer medical officers offered their services in his district. He did not approve of nominations to the service.

Surgeon-Lieutenant-Colonel W. COATES, V.M.S.C., thought that in future campaigns volunteer medical units should as far as possible be kept together in the same batch. The officers should not be separated from their own men. He was in favour of nomination by heads of colleges for commissions in the Royal Army Medical Corps and a modified form of competitive examination afterwards.

Mr. CANTLIE replied that volunteers in Ireland ought to be trained as stretcher-bearers. Students could be caught in the interval between leaving their medical school and settling down in practice if they had been made familiar with the military medical idea through having belonged to medical cadet corps. He would not send a single consulting surgeon or physician to the front in war time who had not done something for his country in peace time by assisting with a cadet corps.

Mr. CANTLIE proposed the following motion which was carried unanimously after being seconded by Surgeon-Lieutenant-Colonel W. COATES:—

> *That it be a recommendation to the Council of the British Medical Association to consider whether the establishment of medical cadet corps in connexion with the medical schools is feasible or desirable, and if so whether the matter should not be brought to the attention of the War Office.*

Mr. R. J. COLLIER read a paper entitled

The Ambulance and Home Nursing Classes of the London School Board.

He dealt with the benefits of ambulance teaching in school boards and its universal importance and utility from a public point of view. He stated that the London School Board had instructed over 16,000 pupils and others, before he joined the school board as a teacher, by the aid of the St. John Ambulance Association, and that in 1900 after the first course nearly 800 teachers passed out of 900. The alacrity with which the teachers and pupils availed themselves of the opportunity afforded was important and indicated the need for such an arrangement.

The PRESIDENT said that the paper was of great public interest.

Mr. J. HALL-EDWARDS (Birmingham) read a paper entitled

Roentgen Ray Work in South Africa.

He reviewed the advent and course of the x ray in surgical work, civil and military. He gave an interesting and detailed account of his work and experiences in South Africa with the x-ray apparatus in the Imperial Yeomanry Hospital.

The PRESIDENT commented on the paper in terms of praise and invited discussion.

Surgeon-General O'DWYER said that military surgeons fully appreciated, and were quite alive to the great value of, the x ray. The x ray had hardly been long enough in existence for elaborate instruction to have been given to the Royal Army Medical Corps in its use, but no doubt that would be fully done at the earliest possible date. A further benefit of the x ray was that a soldier discharged from the army with an obscure injury could be accompanied to some medical man perhaps remote from an x-ray apparatus by a good photograph of his injuries.

Mr. HALL-EDWARDS, in reply, said that in considering the question they must remember that they had at their disposal a method of localising bullets with absolute accuracy and that advances in surgical procedure had considerably lessened the risk attendant upon an operation. They knew that bullets had been retained in the tissues for half a lifetime without producing any serious results. On the other hand, retained bullets had proved a source of irritation after having lain in a quiescent state for years. Whether or not the modern projectile with its cupro-nickel or steel casing would be as inert as the old leaden bullet yet remained to be seen. Their experience in these matters was so far exceedingly limited; nevertheless, there must exist opinions as to the advisability or otherwise of removing bullets the exact position of which was known, it being taken for granted that the operation itself did not involve any serious risk. Not being a surgeon, it would be a piece of presumption on his part to offer any positive opinion, but having been engaged in South Africa in localising bullets, and having seen numerous operations for their removal, he was more than interested in knowing the general opinion of the profession upon this most important subject. He would here quote three cases out of many which had recently come under his observation, and he must admit that when a bullet was located in a position from which it could be removed with ease and certainty it was much safer in the patient's pocket than in his tissues. A private in the 1st Dragoon Guards was shot on Feb. 14th, 1901, at Hout Kraal. He was advancing up a kopje when the bullet struck him. The entrance wound was of about the size of a shilling and presented rough and jagged edges, and was situated just below the iliac crest on the left side. There was no exit wound. The bullet was localised close to the spinal column, between the second and third lumbar vertebræ. The localisation showed that the bullet lay at a depth of one and a half inches from the skin. The only symptom was very slight pain in the back in walking; nevertheless, it was decided to remove it. The bullet was found lying in a sac containing about half an ounce of semi-purulent fluid and several pieces of dead bone from the transverse process of the third lumbar vertebra. The patient made a rapid recovery and was discharged as cured. Although it was impossible to predict what might have occurred had this bullet been allowed to remain, there could be little doubt that all anxiety had passed away with its removal. The next case was one which presented itself at the Central Hospital, Birmingham. A man was admitted suffering from cancer in the throat; after admission it was whispered that 11 years previously he had attempted suicide by shooting himself in the mouth, so he was sent to me The radiograph showed the presence of two bullets deeply situated in the structures of the neck. The case was too far advanced for operative treatment, so he was allowed to go home and there was no record of what had subsequently happened. The third and last case which he quoted was that of a private in the Cameron Highlanders who was shot at Spitz Kop on July 20th, 1900. He was advancing at the double when a bullet struck him in the groin just above the middle of Poupart's ligament. There was no exit wound. On admission to the Imperial Yeomanry Hospital he complained of pain on walking, and the movements of the left hip were not so good as were those of the right. The bullet was localised at a depth of two and a half inches from the surface of the buttock, upon which he was lying during the taking of the radiograph, so that the total depth was little short of three and a half inches. The bullet was found to be imbedded in the neck of the femur and was removed; it was uninjured. The patient made a complete recovery and returned to England with perfect movement in the joint. Mention might be made of several other cases in which retained bullets had been the cause of trouble, but these were sufficient to point to the fact that in many instances they were far better removed.

The meeting then adjourned to the lantern-room where Mr. CUTHBERT WALLACE (London) gave a lantern demonstration of the various types of wounds and injuries to bone and soft parts occurring in the South African campaign The demonstration was well attended and of great interest

A cordial vote of thanks was proposed by Mr. ANDREW CLARK (London) to Deputy Surgeon-General W. G. Don for his genial and able conduct of the business of the section and was carried by acclamation. A like vote was proposed and accorded to the Secretaries for their able and tactful management of the affairs of the section.

DERMATOLOGY.

FRIDAY, AUGUST 2ND.

The following cases were exhibited: A case of Leucodermia and Telangiectatic Atrophodermia following Measles, by Dr. ALFRED EDDOWES (London); and a case of Ichthyosis Hystrix, by Dr. D. G. MACLEOD MUNRO (Cheltenham).

Dr. NORMAN WALKER (Edinburgh) brought forward the following motion:—

> That it is, in the opinion of this meeting, desirable that the Dermatological Section of the Association should meet not less frequently than twice in four years; and that this resolution be forwarded to the Council of the Association.

It was seconded by Dr. T. COLCOTT FOX (London) and carried *nem. con.*

Seborrhœa.

Dr. T. COLCOTT FOX opened a discussion on Seborrhœa, or, as he preferred to term it, "Steatorrhœa." He commenced with a brief consideration of some of the functions and the distributi[illegible] especial reference [illegible] in the production [illegible]. put the questions whether the coil glands could secrete oil in sufficient quantity to form droplets at the pores or a notable oily coating of the surface; and again whether the structure of the sebaceous glands warranted the conclusion that the output of sebum could be greatly increased without their hypertrophy. The views of various authors were discussed at some length. He then gave a recital of views held as to the nature of seborrhœa in regard to the quantitative and qualitative alterations of sebum and pointed out the clinical distinction between seborrhœa oléosa (oily seborrhœa) and seborrhœa sicca (greasy squamous seborrhœa). Pityriasis capitis was held to be a distinct affection, but was grouped by Hebra with seborrhœa sicca as interdependent processes. Seborrhœa was considered by Dr. Fox to be a functional and non-inflammatory disorder, though Cazenave described acné sebacée as an inflammatory disorder. Dr. Fox then dealt with the clinical characters assumed by seborrhœas in different regions and the doubtful character of some affections included under the term, and concluded this part of his paper with a notice of the older conceptions of the etiology. A new chapter was opened by the development of Unna's views as to the non-sebaceous character of both oily and squamous seborrhœa. The former, which should be called [illegible] function of the sudo-[illegible] ch was a superficial [illegible] y pityriasis capitis), [illegible]" Unna's proofs of the inflammatory nature of squamous seborrhœa and the derivation of the grease from the sudoriferous glands were given. The inflammation was, according to Unna, a specific one caused by a definite organism or organisms. Dr. Fox then referred to Sabouraud's views. According to that author pure oily seborrhœa was a microbial infection of the pilo-sebaceous follicles, taking place with the evolution of puberty. A micro-bacillus entered the follicle and the encysting of the colony took place with a formation of a cocoon in the upper third of the follicle. Then followed four reactionary phenomena—viz., sebaceous hyper-secretion, a progressive glandular hypertrophy, inflammation, and poisoning and death of the papilla. The results were the calvities or "alopecia areata" of Bateman. The engrafting of secondary organisms on this substratum of oily seborrhœa produced, according to Sabouraud, polymorphic acne and acne varioliformis, &c. These views were compared with Unna's views on acne, and Dr. Fox expressed his preference for the views of Sabouraud. Pityriasis capitis was a microbial infection independent of oily seborrhœa, according to Sabouraud, and greasy squamous seborrhœa was a desquamative dermatitis engrafted on oily seborrhœa.

Dr. RAYMOND SABOURAUD (Paris) made a communication on the same subject. It was most necessary, he remarked, in the first place, to limit the subject and to define the term "seborrhœa." This word was first used by Fuchs of Göttingen in 1840 to designate sebaceous excretion when it became visible on the skin and made it greasy. The word had been altered from its primitive sense by Hebra, who, under the name of "seborrhœa," designated not only true seborrhœa (oleosa) but also pityriasis (seborrhœa sicca). This was an absolutely deplorable confusion. Pincus, Piffard, van Harlingen, and then Unna, showed that the scale of pityriasis did not come from the depth of the sebaceous glands as Hebra had thought, but that these scales were produced by the exfoliation of the superficial horny epidermis. It was therefore necessary to separate pityriasis essentially from seborrhœa. It was their confusion which darkened all the subject. The forms of pityriasis—that was, of exfoliation of the horny layer—had a microbic flora, a peculiar and specific cause, namely, the grey-cultured coccus and the "bottle bacillus." They had a special elementary lesion—the scale. They might exist without any fatty state of the skin, and when they were found in connexion with true seborrhœa it was by superimposition of two diseases. They were grafted on to seborrhœic skin and not properly seborrhœic by themselves. Seborrhœa (in its etymological sense—flow of sebum) was the hypersecretion of the sebaceous glands. It was never scaly; it was always and exclusively fatty. It was this condition to which the term "seborrhœa" should be limited and which formed the topic of discussion that day. Having thus defined the malady Dr. Sabouraud proceeded to remark that seborrhœa existed in two forms: a moist type ("acne sebacea" of Biett, Cazenave, "flux sebaceus" of Rayer, "seborrhagia" of Fuchs, "seborrhœa oleosa" of H. Hebra, "steatorrhœa" of E. Wilson), and a cystic type (acne comedo or acne punctata of all authors). The elementary lesion of seborrhœa was a fatty plug which oozed from the sebaceous ducts when sebaceous skin was squeezed between the fingers. This plug was microbic; it was made up of pure fat containing an enormous quantity of very small bacilli, which existed under the form either of separate elements or of composite mycelial clumps. This microbic colony was absolutely constant and it was positively pure in each seborrhœic follicle. It existed in each follicle as soon as the sebaceous flow made the skin shiny and greasy. The second clinical form of seborrhœa was the comedo. The comedo was only the cystic transformation of a primitive seborrhœic plug. This special transformation occurred only in one seborrhœic plug among thousands of others which would persist as seborrhœic plugs and never became comedones. After a time the comedo was almost always infected by the common cocci of the human skin. The most common infection was by the grey-cultured coccus.[1] It made the red acneic papule, the pustule of superficial or of deep acne (acne indurata), thus bringing about all the varieties of polymorphous acne. The comedo might be infected by more virulent microbes—for example, by the staphylococcus aureus. Thus was caused acne necrotica, varioliformis, acneic furunculosis, chronic furunculosis of the neck, sycosis, and acne cheloid. This acne was only the result of infections secondary to the original micro-bacillar seborrhœa. Micro-bacillar seborrhœa and acne synchronised with the sexual development. Its localisations all centred round the vertical axial line, the centre of the face, the inter-scapular space, the back of the neck, the presternal region, a peri-umbilical ring, another perigenital, another perianal, and on the region of the sacrum. The localisation on the centre of the scalp gave rise to common baldness of man. Baldness was a micro-bacillar seborrhœa of the vertex. Each follicle which lost its hair was first invaded by a colony of the micro-bacillus. The phenomena of alopecia were similar on all the parts of the body, only on some of them they were less visible. The same micro-bacillus was certainly present in all seborrhœic manifestations, for cultures (which were in all cases difficult to obtain) were possible and were the same in all cases. These cultures grew on acid media; they were conical in form and of a red colour. In the cultures the bacillus had the same form, the same dimensions, and the same selective methods of staining (Gram). Dr. Sabouraud tl[illegible] obtain cultures of [illegible] of the cultures, d[illegible] sions to be drawn from his researches into seborrhœa were as follows:—1. The words "acne sebacea," "sebaceous flux," "seborrhœa," "seborrhagia," and "steatorrhœa" signified the same morbid phenomenon, which was hypersecretion of the sebaceous glands. This disease had a constant microbic expression—namely, the seborrhœic micro-bacillus. 2. From seborrhœa thus defined all acnes arose which were either the result of spontaneous transformations in the microbic seborrhœic plug or of secondary infections of the elementary seborrhœic lesion. Of course, seborrhœa constituted a cutaneous soil propitious for the development of a multitude of skin diseases differing in their cause and nature. There were, for instance, the seborrhœic wart of old persons, the molluscum contagiosum of Bateman, &c. There were also the various forms of pityriasis. 3. The different forms of pityriasis constituted a special and independent skin disease. They were not seborrhœic. They had a special lesion—the scale, which consisted of epidermic horny exfoliation. They resulted from a special microbic growth which was *not* a micro-bacillus. They were morbid processes entirely different from seborrhœa, but which were, nevertheless, frequently superimposed on seborrhœa. The seborrhœa was for them an elective ground and substratum. On seborrhœic skin they produced circinate pityriasis—the circinaria of Payne. On the scalp they caused dry and fatty pityriasis. The term "seborrhœic eczema" of Unna signified a hybrid mixture of pityriasis and seborrhœa, which was as frequent as pure seborrhœa, but the original clinical types of which must be all the more carefully distinguished, inasmuch as they generally co-existed on the same patient

---

[1] See Discussion on the Rôle of Cocci in the Pathology of Diseases of the Skin (Wednesday), THE LANCET, August 3rd, 1901, p. 403.

Dr. ALLAN JAMIESON (Edinburgh) doubted whether the fatty accumulation in seborrhœic dermatitis was due to microbic action, though the comedo was undoubtedly of microbic origin. In normal conditions if the skin was covered up a branny accumulation took place. Might not this be due to micro-organisms of a kind hitherto thought to be innocuous?

Dr. NORMAN WALKER (Edinburgh) remarked that the subject bristled with difficulties. What were the meanings of "seborrhœa oleosa" and of "pityriasis sicca." He had tried very hard many times to cultivate the organism to which Dr. Sabouraud referred, but had only succeeded once, in a case of hirsuties. Many suffered from oily skins but did not get bald. How was this to be explained on Dr. Sabouraud's statement that baldness resulted from seborrhœa? The term "seborrhœic eczema" was, he admitted, very unfortunate. As to the relation of seborrhœic dermatitis and psoriasis—conditions which Unna held to be identical, mainly on the grounds that they both started in the scalp—there were, without doubt, many cases of scurfy scalp in which it was very difficult to say whether the case was one of psoriasis of the scalp or pityriasis capitis. Seborrhœic dermatitis was a scaly catarrhal affection of the skin, a process differing essentially from seborrhœa. The fat glands were not, in his opinion, involved in seborrhœic eczema.

Dr. H. G. BROOKE (Manchester) remarked that he did not believe that there was any excessive exudation from the sebaceous glands. Seborrhœic dermatitis was no doubt an infective disease and the infectivity varied with the virulence of the organism. Fat was, he felt sure, formed in the epidermis cells and it was the destruction of the fat in these which led to pityriasis. The mutual dependence between psoriasis and seborrhœic dermatitis was clinically very evident.

Dr. J. M. MACLEOD (London) wished to refer to the question of alopecia of the patchy type which occurred so commonly in children. In six patients who averaged nine years of age he had excised small pieces of skin which were covered with sebaceous-looking plugs, but he had found no great alteration of the sebaceous glands. In all of them there were œdema and proliferation of rete Malpighii. Near the orifices of the follicles there was a deficiency of the granular layer. These changes amounted to an acanthosis and œdema and to a certain extent a parakeratosis. The conditions, therefore, were those of seborrhœic dermatitis. Micro-organisms were very difficult to find in the skin.

Dr. HENRY WALDO (Bristol) remarked that the subject was very much simplified by their being able to exclude seborrhœa sicca. Did seborrhœa oleosa depend on organisms or not was the main question before them. He had always regarded coronal baldness as unconnected with seborrhœa. It was not a curable affection. Could alopecia areata be treated by the hypodermic injection of toxins? Seborrhœa was often associated with lupus vulgaris and lupus erythematosus. Was there any association between these diseases and the micro-bacillus referred to?

Dr. T. D. SAVILL (London) wished to ask Dr. Sabouraud how he explained the production of two such clinically distinct lesions as the comedo and papule of acne and the papules and oily scales of seborrhœa by the same micro-bacillus? The fact of acne arising chiefly at puberty was not for him a *fact against* the bacillary origin of that disease. There was at this epoch of life a sudden outburst of physiological activity in all the seborrhœic glands throughout the body, as witnessed by the appearance of hair in various regions, and this offered a predisposition for pathological activity also. He thought that the grouping of alopecia areata, acne, and the various seborrhœic processes under one pathological factor threw a flood of light on these affections. But the question which he had asked offered, he believed, considerable difficulty.

Dr. DUBREUILH (Bordeaux) regarded the hypothesis suggested by Dr. Sabouraud as a most plausible and most satisfactory one. He wished to allude to the clinical aspect and the greatest difficulty to his mind was that baldness was not by any means constantly associated with seborrhœa. Many greasy-skinned people did not lose their hair and others who became bald had not greasy skins.

Dr. LESLIE ROBERTS (Manchester) thought that the clinical picture of the disease was too well established for them to be able to throw over the term "seborrhœic eczema." It was quite likely that there was still some connexion between seborrhœa and eczema. The former might prepare the skin for the latter, and although there were objections to the name he doubted the expediency of removing it from the nomenclature of dermatology.

Dr. COLCOTT FOX, in reply, remarked that in certain cases of alopecia they could almost invariably find that some of the sebaceous follicles were plugged. As regarding the cause of death of the hair there were two opposite views. Dr. Sabouraud held that the fall of hair was due to the action of a toxin on papilla whence the hair grew. On the other hand, Dr. Unna held that the fall of hair was produced by the plugging of the hair follicle. As to the connexion between seborrhœa and psoriasis his view was that although in the scalp it was very hard to distinguish them that was no reason for confusing two such distinct diseases.

Dr. SABOURAUD, in reply, remarked that the more a woman had a tendency to hair on the face the more she had a tendency to seborrhœa. All the seborrhœic localities were at or near the median line of the body; they were axial in distribution. On the other hand, as regards men, there was no baldness without seborrhœa. In reply to Dr. Savill's question he remarked that the same microbic process was capable of producing both an acne and seborrhœic papule because of the mechanical conditions—the blocking of the follicle and the superimposition of other cocci upon the seborrhœic process.

Dr. LESLIE ROBERTS read a paper on

The Action of Arsenic on the Healthy Tissues of the Skin.

He commenced by remarking that they could learn more of the action of arsenic on the tissues of the body from the study of its chemical properties and elementary action than they could from mere clinical experience. He dealt first with the wide distribution of arsenic in nature and then passed on to consider its dynamic action within the body. He was of opinion that the histological changes produced in the tissues by arsenic were not directly due to the arsenic itself but to the agency of nascent oxygen produced by the action of cell-protoplasm on arsenious acid and arsenic acid. Having discussed the question of the normal distribution of arsenic in the human body Dr. Leslie Roberts then passed on to consider in their order the effects of arsenic oxidation on the tissues of the skin—namely, (1) pigmentation, (2) hyperkeratinisation, (3) desquamation, (4) atrophy, and (5) fatty degeneration. He concluded that arsenic was not merely a drug possessing curative powers; that it was not necessarily an irritant poison; that arsenic was not a poison in itself but that its action was initiated and determined by the tissues themselves; that its effects were essentially of a nutritive order brought about by the agency of nascent oxygen; that these effects were beneficent to the organism when the oxidation was slow but injurious when too rapid; and that the more highly organised the cell, the more unstable its protoplasm and the more rapid its metabolic processes, so much the more readily did it feel and manifest the dynamic action of arsenic.

Dr. H. RADCLIFFE CROCKER (London) and Mr. GEORGE PERNET (London) contributed a paper on

Epithelioma Supervening on Arsenical Keratosis.

Cancer as a result of arsenical keratosis was sufficiently rare for any fresh case to be placed on record. The subject had been dealt with recently in Nielsen's paper on Melanosis and Keratosis Arsenicalis [2] The patient forming the subject of the paper was a man, aged 60 years, who consulted Dr Radcliffe Crocker in March, 1900, for a small painful sore situated on the ulnar border of the right hand close to the metacarpo phalangeal joint of the little finger, and of six months' duration It had begun as a "mattery speck" two years previously and it had gradually increased in size There was an enlarged gland in the corresponding axilla There had also been a sore of the left index finger which had healed Scattered about the hands were several small warty specks and the epidermis was slightly pitted, but there was not general arsenical keratosis The patient had suffered from psoriasis from the age of 20 years, for which he had had arsenic, but he had not had any treatment for 38 years, and as far as he knew he had not taken arsenic since then On the whole the psoriasis had got better the last two or three years The growth was excised in April, 1900 by Mr James Cantlie, but it returned in October Histological examination of the growth removed at the first operation showed proliferation of the prickle cells of the epidermis and in parts commencing invasion of the corium This was much more marked in the tissues removed at the second operation. Keratosis and acanthosis with epitheliomatous growth, together with leucocytic cell infiltration of the papillary and deeper layers of the corium, were noted. Numerous mast cells were present, especially about the sweat coils Interesting features of the case were that the warty growths persisted so long after the arsenic was left off and that from these the cancer developed after so long an interval

Dr ELDON PRATT (Cardiff) read the notes of

A Case of Purpura Hæmorrhagica Associated with General Tuberculosis

The patient was a man, aged 27 years, who was admitted with pyrexia (the chart of which was exhibited) Three weeks later there were epistaxis and hæmaturia and melæna A few crepitations were heard in the lungs Suppuration of the parotids occurred Repeated hæmorrhages occurred and purpuric eruption appeared At the necropsy generalised tuberculosis was evident

THE ANNUAL MUSEUM.

(Concluded from page 485)

V —MINERAL WATERS, BEVERAGES, &c

Cheltenham has mineral waters of its own and this fact possibly accounts for the comparatively small number and variety of exhibits displayed in this section The Cheltenham Corporation have acquired the chief springs and undertake the supply of the waters At the Montpellier Spa there are two disti unt of magnesiu while the other The sulphated water may be regarded as a mild Carlsbad water, having a similar therapeutic effect It, however, may be taken in a concentrated form, the water being evaporated down to a convenient strength for the purpose Messrs Schweppes, of 53, Berners street, London, W exhibited specimens of the Malvern waters, both plain and aerated The purity of Malvern water is well known In addition, this firm exhibited some porcelain-lined syphons, the construction of which we have previously described It need only be added that the precautions taken by Messrs Schweppes to ensure the purity of mineral waters in bottle or syphon are admirable. A very interesting model of the Roman Thermæ at Bath was exhibited by the Bath Corporation In the report of THE LANCET Commission on "Bath as a Health Resort," published in THE LANCET of Oct 14th, 1899 p 1055, a reproduced picture of these interesting remains was printed. The analyses of the waters made in THE LANCET Laboratory were also given in this report at some length Specimens of the well known mineral waters of Harrogate were shown by the Harrogate Corporation. Amongst these were the well known sulphuretted hydrogen waters and chalybeate waters Models were shown of the various bath appliances used in Harrogate as well as photographic views The natural waters of Vichy in bottle were shown by Messrs Ingram and Royle of East Paul's Wharf, 26 Upper Thames-street, London, E.C The exhibit included Vichy salts and pastilles and also the Carlsbad natural mineral waters and the genuine Sprudel salt. They are also agents for the supply of the natural aperient water, Hunyadi Janos, specimens of which formed a feature of the stall The Apollinaris Company of 4 Stratford-place, Oxford-street, London, W, had a large well-decorated stall on which were specimens of Apenta water and Friedrichshall water as representing natural bitter waters, and Apollinaris and Johannis as sparkling table waters The latter is now supplied containing added lithia or potash The exhibition of these drugs in a natural water probably presents some advantages The saline and chalybeate waters of Leamington were shown by the Corporation of Leamington The waters may be obtained plain, aerated, or concentrated The managers are keenly alive to the requirements of visitors and some important improvements have recently been made in regard to the equipments of this "Royal spa." An interesting series of the natural wines of Australia was shown by the South Australian Government Bonded Depôt (Walbrook, London, E C) They are known as the "Orion" brand and include wines of the claret, burgundy, and hock types In addition was shown the 'Orion' liqueur brandy, a pure wine spirit, as we have already indicated in our analytical columns Stower's lime juice cordial and clarified lemon squash were exhibited on the stall of Messrs Alexander Riddle and Co of 36 and 38, Commercial street, London, E The point about these preparations is that the aroma and flavour of the fresh lime and lemon respectively are retained in the expressed juice Close by, Messrs Stephen Smith and Co of Malmesbury road, Bow, London E, submitted specimens of various wines to those who cared to taste them These included coca wine, beef wine and a special burgundy The exhibition of Messrs Feltoe and Smith of 25, Augustus street, Regent's-park, London N W comprised their "specialité" lime juice cordial and lemon squash Some excellent "lemon squash crystals" were also shown which are useful for the extemporaneous preparation of a refreshing lemonade.

VI —PUBLICATIONS

There were several stalls devoted to the display of medical works, temperature charts, clinical tables, &c This section is a comparatively new feature of the exhibition, and is of increasing interest judging from the number of medical visitors found turning over the pages of the publications submitted The following publishers were represented —Messrs Rebman, Limited, of 129 Shaftesbury-avenue, London W C (this firm also exhibited various therapeutic serum preparations contained in hermetically sealed flasks), Mr B Allsop, of the *Times* Office, Shipley, Yorkshire who demonstrated his handy A B C system of medical bookkeeping, Messrs John Wright and Co, of Bristol, Mr Henry Kimpton of 13, Furnival street, Holborn, London, E C, Messrs W B Saunders and Co, of 161, Strand, London, W C, and Philadelphia, and Messrs Macmillan, of St Martin's-court, London, W C

VII —MISCELLANEOUS

What we have chosen to classify as the miscellaneous section of the exhibits presented a novel feature this year in the shape of an exhibit of motor cars and broughams for medical men Mr D H Morgan for example, of Clarence-street, Cheltenham, exhibited a three and a half horse power motor car with two speeds and fitted with a hood Mr Alfred Miles, of Cheltenham, showed a collection of carriages comprising light broughams phaetons, and carts Similarly Mr W B Moore of Stourbridge, has designed a hooded gig specially adapted for medical men, whilst in addition he showed a neat one horse ambulance Messrs Boyd and Co, of 296, Regent-street, London, W, exhibited an ulster for the use of medical men and a woollen material called "naquatum," which is said to be porous though absolutely waterproof The "Aertex" cellular clothing of the Cellular Clothing Company, Limited, of 72 and 73 Fore street, London, E C, was inspected with interest This clothing is designed to protect the body as well as to allow the escape of excretory products It is, therefore, adapted for garments worn next to the skin. Office time saving appliances were represented in the "Cen s" automatic letter and card files, the invention of Mr T Bowater Vernon of 10 John street, Adelphi, London, W C We have already pointed out the excellence of this system of keeping letters and papers in their place and when they can be found The system is of acknowledged usefulness to medical men and we understand that it is in use in many hospitals either the result of spontaneous transformations in the microbic seborrhœic plug or of secondary infections of the elementary seborrhœic lesion. Of course, seborrhœa constituted a cutaneous soil propitious for the development of a multitude of skin diseases differing in their cause and nature. There were, for instance, the seborrhœic wart of old persons, the molluscum contagiosum of Bateman, &c. There were also the various forms of pityriasis. 3. The different forms of pityriasis constituted a special and independent skin disease. They were not seborrhœic. They had a special lesion—the scale, which consisted of epidermic horny exfoliation. They resulted from a special microbic growth which was not a micro-bacillus. They were morbid processes entirely different from seborrhœa, but which were, nevertheless, frequently superimposed on seborrhœa. The seborrhœa was for them an elective ground and substratum. On seborrhœic skin they produced circinate pityriasis—the circinaria of Payne. On the scalp they caused dry and fatty pityriasis. The term "seborrhœic eczema" of Unna signified a hybrid mixture of pityriasis and seborrhœa, which was as frequent as pure seborrhœa, but the original clinical types of which must be all the more carefully distinguished, inasmuch as they generally co-existed on the same patient.

---

[2] Selected Essays and Monographs New Sydenham Society, vol clxx, 1900, p 249

Dr. Allan Jamieson (Edinburgh) doubted whether the fatty accumulation in seborrhœic dermatitis was due to microbic action, though the comedo was undoubtedly of microbic origin. In normal conditions if the skin was covered up a branny accumulation took place. Might not this be due to micro-organisms of a kind hitherto thought to be innocuous?

Dr. Norman Walker (Edinburgh) remarked that the subject bristled with difficulties. What were the meanings of "seborrhœa oleosa" and of "pityriasis sicca." He had tried very hard many times to cultivate the organism to which Dr. Sabouraud referred, but had only succeeded once, in a case of hirsuties. Many suffered from oily skins but did not get bald. How was this to be explained on Dr. Sabouraud's statement that baldness resulted from seborrhœa? The term "seborrhœic eczema" was, he admitted, very unfortunate. As to the relation of seborrhœic dermatitis and psoriasis—conditions which Unna held to be identical, mainly on the grounds that they both started in the scalp—there were, without doubt, many cases of scurfy scalp in which it was very difficult to say whether the case was one of psoriasis of the scalp or pityriasis capitis. Seborrhœic dermatitis was a scaly catarrhal affection of the skin, a process differing essentially from seborrhœa. The fat glands were not, in his opinion, involved in seborrhœic eczema.

Dr. H. G. Brooke (Manchester) remarked that he did not believe that there was any excessive exudation from the sebaceous glands. Seborrhœic dermatitis was no doubt an infective disease and the infectivity varied with the virulence of the organism. Fat was, he felt sure, formed in the epidermis cells and it was the destruction of the fat in these which led to pityriasis. The mutual dependence between psoriasis and seborrhœic dermatitis was clinically very evident.

Dr. J. M. Macleod (London) wished to refer to the question of alopecia of the patchy type which occurred so commonly in children. In six patients who averaged nine years of age he had excised small pieces of skin which were covered with sebaceous-looking plugs, but he had found no great alteration of the sebaceous glands. In all of them there were œdema and proliferation of rete Malpighii. Near the orifices of the follicles there was a deficiency of the granular layer. These changes amounted to an acanthosis and œdema and to a certain extent a parakeratosis. The conditions, therefore, were those of seborrhœic dermatitis. Micro-organisms were very difficult to find in the skin.

Dr. Henry Waldo (Bristol) remarked that the subject was very much simplified by their being able to exclude seborrhœa sicca. Did seborrhœa oleosa depend on organisms or not was the main question before them. He had always regarded coronal baldness as unconnected with seborrhœa. It was not a curable affection. Could alopecia areata be treated by the hypodermic injection of toxins? Seborrhœa was often associated with lupus vulgaris and lupus erythematosus. Was there any association between these diseases and the micro-bacillus referred to?

Dr. T. D. Savill (London) wished to ask Dr. Sabouraud how he explained the production of two such clinically distinct lesions as the comedo and papule of acne and the papules and oily scales of seborrhœa by the same micro-bacillus? The fact of acne arising chiefly at puberty was not for him a fact against the bacillary origin of that disease. There was at this epoch of life a sudden outburst of physiological activity in all the seborrhœic glands throughout the body, as witnessed by the appearance of hair in various regions, and this offered a predisposition for pathological activity also. He thought that the grouping of alopecia areata, acne, and the various seborrhœic processes under one pathological factor threw a flood of light on these affections. But the question which he had asked offered, he believed, considerable difficulty.

Dr. Dubreuilh (Bordeaux) regarded the hypothesis suggested by Dr. Sabouraud as a most plausible and most satisfactory one. He wished to allude to the clinical aspect and the greatest difficulty to his mind was that baldness was not by any means constantly associated with seborrhœa. Many greasy-skinned people did not lose their hair and others who became bald had not greasy skins.

Dr. Leslie Roberts (Manchester) thought that the clinical picture of the disease was too well established for them to be able to throw over the term "seborrhœic eczema." It was quite likely that there was still some connexion between seborrhœa and eczema. The former might prepare the skin for the latter, and although there were objections to the name he doubted the expediency of removing it from the nomenclature of dermatology.

Dr. Colcott Fox, in reply, remarked that in certain cases of alopecia they could almost invariably find that some of the sebaceous follicles were plugged. As regarding the cause of death of the hair there were two opposite views. Dr. Sabouraud held that the fall of hair was due to the action of a toxin on papilla whence the hair grew. On the other hand, Dr. Unna held that the fall of hair was produced by the plugging of the hair follicle. As to the connexion between seborrhœa and psoriasis his view was that although in the scalp it was very hard to distinguish them that was no reason for confusing two such distinct diseases.

Dr. Sabouraud, in reply, remarked that the more a woman had a tendency to hair on the face the more she had a tendency to seborrhœa. All the seborrhœic localities were at or near the median line of the body; they were axial in distribution. On the other hand, as regards men, there was no baldness without seborrhœa. In reply to Dr. Savill's question he remarked that the same microbic process was capable of producing both an acne and seborrhœic papule because of the mechanical conditions—the blocking of the follicle and the superimposition of other cocci upon the seborrhœic process.

Dr. Leslie Roberts read a paper on

The Action of Arsenic on the Healthy Tissues of the Skin.

He commenced by remarking that they could learn more of the action of arsenic on the tissues of the body from the study of its chemical properties and elementary action than they could from mere clinical experience. He dealt first with the wide distribution of arsenic in nature and then passed on to consider its dynamic action within the body. He was of opinion that the histological changes produced in the tissues by arsenic were not directly due to the arsenic itself but to the agency of nascent oxygen produced by the action of cell-protoplasm on arsenious acid and arsenic acid. Having discussed the question of the normal distribution of arsenic in the human body Dr. Leslie Roberts then passed on to consider in their order the effects of arsenic oxidation on the tissues of the skin—namely, (1) pigmentation, (2) hyperkeratinisation, (3) desquamation, (4) atrophy, and (5) fatty degeneration. He concluded that arsenic was not merely a drug possessing curative powers; that it was not necessarily an irritant poison; that arsenic was not a poison in itself but that its action was initiated and determined by the tissues themselves; that its effects were essentially of a nutritive order brought about by the agency of nascent oxygen; that these effects were beneficent to the organism when the oxidation was slow but injurious when too rapid; and that the more highly organised the cell, the more unstable its protoplasm and the more rapid its metabolic processes, so much the more readily did it feel and manifest the dynamic action of arsenic.

Dr. H. Radcliffe Crocker (London) and Mr. George Pernet (London) contributed a paper on

Epithelioma Supervening on Arsenical Keratosis.

Cancer as a result of arsenical keratosis was sufficiently rare for any fresh case to be placed on record. The subject had been dealt with recently in Nielsen's paper on Melanosis and Keratosis Arsenicalis [2] The patient forming the subject of the paper was a man, aged 60 years, who consulted Dr Radcliffe Crocker in March, 1900, for a small painful sore situated on the ulnar border of the right hand, close to the metacarpo phalangeal joint of the little finger, and of six months' duration It had begun as a "mattery speck' two years previously and it had gradually increased in size There was an enlarged gland in the corresponding axilla There had also been a sore of the left index finger which had healed Scattered about the hands were several small warty specks and the epidermis was slightly pitted, but there was not general arsenical keratosis The patient had suffered from psoriasis from the age of 20 years, for which he had had arsenic, but he had not had any treatment for 38 years, and as far as he knew he had not taken arsenic since then On the whole the psoriasis had got better the last two or three years The growth was excised in April, 1900, by Mr James Cantlie, but it returned in October Histological examination of the growth removed at the first operation showed proliferation of the prickle cells of the epidermis and in parts commencing invasion of the corium This was much more marked in the tissues removed at the second operation. Keratosis and acanthosis with epitheliomatous growth, together with leucocytic cell infiltration of the papillary and deeper layers of the corium, were noted. Numerous mast cells were present, especially about the sweat coils Interesting features of the case were that the warty growths persisted so long after the arsenic was left off and that from these the cancer developed after so long an interval

Dr **Eldon Pratt** (Cardiff) read the notes of

A Case of Purpura Hæmorrhagica Associated with General Tuberculosis

The patient was a man, aged 27 years who was admitted with pyrexia (the chart of which was exhibited) Three weeks later there were epistaxis and hæmaturia and melæna A few crepitations were heard in the lungs Suppuration of the parotids occurred Repeated hæmorrhages occurred and purpuric eruption appeared At the necropsy generalised tuberculosis was evident

THE ANNUAL MUSEUM.

(*Concluded from page 483*)

V —MINERAL WATERS, BEVERAGES, &c

Cheltenham has mineral waters of its own and this fact possibly accounts for the comparatively small number and variety of exhibits displayed in this section The Cheltenham Corporation have acquired the chief springs and undertake the supply of the waters At the Montpellier Spa there are two distinct waters, one containing a notable amount of magnesium sulphate in association with sodium salts, while the other is an alkaline saline water without magnesia. The sulphated water may be regarded as a mild Carlsbad water, having a similar therapeutic effect It, however, may be taken in a concentrated form, the water being evaporated down to a convenient strength for the purpose Messrs Schweppes, of 53 Berners-street, London, W exhibited specimens of the Malvern waters both plain and aerated The purity of Malvern water is well known In addition, this firm exhibited some porcelain lined syphons, the construction of which we have previously described It need only be added that the precautions taken by Messrs Schweppes to ensure the purity of mineral waters in bottle or syphon are admirable '
Roman Thermæ at Bath
tion In the report of Th
Health Resort,' published in THE LANCET of Oct 14th, 1899, p 1055, a reproduced picture of these interesting remains was printed The analyses of the waters made in THE LANCET Laboratory were also given in this report at some length Specimens of the well-known mineral waters of Harrogate were shown by the Harrogate Corporation. Amongst these were the well known sulphuretted hydrogen waters and chalybeate waters Models were shown of the various bath appliances used in Harrogate as well as photographic views The natural waters of Vichy in bottle were shown by Messrs Ingram and Royle of East Paul's Wharf, 26, Upper Thames-street, London, E.C The exhibit included Vichy salts and pastilles and also the Carlsbad natural mineral waters and the genuine Sprudel salt. They are also agents for the supply of the natural aperient water, Hunyadi Janos, specimens of which formed a feature of the stall The Apollinaris Company of 4, Stratford place, Oxford-street, London, W, had a large well-decorated stall on which were specimens of Apenta water and Friedrichshall water as representing natural bitter waters, and Apollinaris and Johannis as sparkling table waters The latter is now supplied containing added lithia or potash The exhibition of these drugs in a natural water probably presents some advantages The saline and chalybeate waters of Leamington were shown by the Corporation of Leamington The waters may be obtained plain, aerated, or concentrated The managers are keenly alive to the requirements of visitors and some important improvements have recently been made in regard to the equipments of this "Royal spa" An interesting series of the natural wines of Australia was shown by the South Australian Government Bonded Depôt (Walbrook, London, E C) They are known as the "Orion" brand and include wines of the claret, burgundy, and hock types. In addition was shown the 'Orion" liqueur brandy, a pure wine spirit, as we have already indicated in our analytical columns Stower's lime-juice cordial and clarified lemon squash were exhibited on the stall of Messrs Alexander Riddle and Co of 36 and 38, Commercial street, London, E. The point about these preparations is that the aroma and flavour of the fresh lime and lemon respectively are retained in the expressed juice Close by, Messrs Stephen Smith and Co of Malmesbury-road, Bow, London E, submitted specimens of various wines to those who cared to taste them These included coca wine beef wine and a special burgundy The exhibition of Messrs Feltoe and Smith of 25, Augustus street, Regent's-park, London, N W comprised their "spécialité" lime-juice cordial and lemon squash Some excellent "lemon squash crystals" were also shown which are useful for the extemporaneous preparation of a refreshing lemonade

VI —PUBLICATIONS

There were several stalls devoted to the display of medical works, temperature charts, clinical tables, &c This section is a comparatively new feature of the exhibition, and is of increasing interest judging from the number of medical visitors found turning over the pages of the publications submitted The following publishers were represented —Messrs Rebman, Limited, of 129, Shaftesbury avenue, London, W C (this firm also exhibited various therapeutic serum preparations contained in hermetically sealed flasks); Mr B Allsop of the *Times* Office, Shipley, Yorkshire, who demonstrated his handy A B C system of medical bookkeeping, Messrs John Wright and Co, of Bristol, Mr Henry Kimpton, of 13, Furnival street, Holborn, London, E C, Messrs W B Saunders and Co, of 161, Strand, London, W C, and Philadelphia, and Messrs Macmillan, of St Martin's court, London, W C

VII —MISCELLANEOUS

What we have chosen to classify as the miscellaneous section of the exhibits presented a novel feature this year in the shape of an exhibit of motor cars and broughams for medical men Mr D H Morgan, for example, of Clarence-street, Cheltenham, exhibited a three and a half horse power motor car with two speeds and fitted with a hood Mr Alfred Miles of Cheltenham, showed a collection of carriages comprising light broughams, phaetons, and carts. Similarly Mr W B Moore of Stourbridge, has designed a hooded gig specially adapted for medical men, whilst in addition he showed a neat one horse ambulance Messrs. Boyd and Co, of 296, Regent-street, London, W, exhibited an ulster for the use of medical men and a woollen material called "aquatum" which is said to be porous though absolutely waterproof The "Aertex" cellular clothing of the Cellular Clothing Company, Limited, of 72 and 73 Fore-street, London, E C, was inspected with interest This clothing is designed to protect the body as well as to allow the escape of excretory products It is, therefore, adapted for garments worn next to the skin Office time saving appliances were represented in the "Ceres" automatic letter and card files, the invention of Mr T Bowater Vernon of 10, John street, Adelphi, London, W C We have already pointed out the excellence of this system of keeping letters and papers in their place and where they can be found The system is of acknowledged usefulness to medical men and we understand that it is in use in many hospitals.

Correspondence.

"Audi alteram partem."

"THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION AND THE REPORT OF THE CONSTITUTIONAL COMMITTEE."

To the Editors of THE LANCET.

SIRS,—The letter of Dr. John Ince in THE LANCET of August 17th, p. 489, must have been perused with much interest by many of your readers. Dr. Ince is quite right in supposing that the "coercion" proposed by the British Medical Association would be resented, and that the formation of the profession into a trades union would be considered derogatory. The General Medical Council alone has legal authority to coerce, and men with the courage of their convictions will snap their fingers at laws which there is no power to enforce. There is no trades union, so far as I know, which does not aim at promoting the sordid interests of its own particular class and at ignoring absolutely the welfare of the community at large. It is not difficult to foresee what the opinion of the general public will be with regard to the first learned profession which ventures to become a trades union by imbibing the philosophy of the joiner, the bricklayer, the dock striker, and the like. It seems to me that the medico-political agitator has arisen within our own ranks, and that he will, if he can (but he cannot), compel all and every one of us to obey all such rules, financial or ethical, as he can persuade a majority to formulate. And in the voting for such rules the rawest recruits, the least experienced and the lowest qualified, will exercise an equal vote with the oldest, the most experienced, and the best qualified members of our profession. By all means let us urge upon the General Medical Council all such reform as is needed, but to set up a rival authority whose weapon, in the absence of legal power, could only consist of boycottings, of ostracisms, of slanders, and of refusals to call into consultation those who might not belong to the medical trades union, would only be to court degradation of the profession and unending strife.

I am, Sirs, yours faithfully,
JAMES RYLEY, M.D. Lond.
Great Yarmouth, August 20th, 1901.

HARVEST BUGS.

To the Editors of THE LANCET.

SIRS,—The effects produced by the bites of the "harvest bug" are so remarkable, so unpleasant, and in certain districts and seasons so common that it is strange that almost no attention is paid to the subject in medical literature. I can find no reference to it in any text-book on medicine or dermatology, and it is not found in Neale's Digest. The animal is a minute, bright scarlet, almost spherical, six-legged larva of the *Trombidium holosericum*—Linn. : of the family Trombidium, order Acarina. This red larva is known as *rouget* in France, and its life-history has been fully investigated by M. P. Mégnin. The eggs producing the larvæ are laid in June and July and the larvæ are active and numerous during July and August; at the end of the latter month they disappear and hibernate, eventually becoming eight-legged nymphæ which are vegetable feeders and of two sexes. The larva has sharp mandibles with which it burrows under the skin of its host and imbibes blood or juices, swelling up to about five times its original size, the head and thorax remaining the same bulk as before. It inhabits dry, grassy places on chalky soil and near the sea. It exists all over Europe, even in Scotland and Norway, and a form probably identical is found in Mexico. It attaches itself to domestic and furry animals (rodents, &c.), and even to other insects. It finds its way on to human beings by their feet, commencing to bite round the ankles. The bites are generally limited to the ankles, the waist (in women), and round the neck and upper chest. The bites are peculiarly virulent to many ladies and children, forming in a few hours small circular ulcers which itch and burn more than any other insect bite, though the inflammatory swelling is very slight. They are said by van Beneden to attach themselves to the roots of hairs, but this has never been the case in the severe instances in which my advice has been sought. They travel with great activity about the body and it is quite impossible to catch them. They comparatively seldom attack men, as very moderately thick stockings and drawers prevent them from biting. The openwork stockings worn by ladies give them an excellent opening for attack. In many women they produce an acute urticaria which is not limited to the seat of the bite, but may affect the whole body. This severe constitutional effect is said to be rare in England, but I have seen it occasionally and it has evidently been frequent this summer from the enormous numbers of the acari produced. I noted them trooping by dozens out of a garden in the Isle of Wight over the window-sills into the rooms. During the heat of day they seem to remain quiescent and mostly begin to bite in the late afternoon. Many persons are peculiarly susceptible to insect bites and apparently peculiarly attractive to insects, and in such subjects the constitutional disturbance produced by the harvest bug is very great and renders life a burden for many weeks in hot summers.

The only remedies are to keep the grass near the house well mown and watered, to wear thick stockings and close-fitting drawers, and to keep the ankles and legs covered with some essential oil (eucalyptus with a small quantity of clove oil), and not to sit out of doors. To find the larva under the skin and dig it out with a needle is commonly recommended, but it is an almost hopeless task.

The best account of the life-history of this pest is in "Annales des Sciences Naturelles," sixth series, vol. iv., 1876. I am, Sirs, yours faithfully,
Westerham, August 21st, 1901. A. MAUDE.

*** The intense irritation set up in many people by these annoying little creatures is well known to us. As a matter of secondary interest we may remark that there seems to be some doubt as to what a "harvest bug" really is. The opinion of Mégnin as given above is that the bug is the hexapod stage of *Trombidium holosericum.* But according to Gould's "Dictionary of Medicine," the harvest bug, or *rouget* of the French, is the *Tetranychus autumnalis* of Shaw, otherwise *Leptus autumnalis* or *Trombidium autumnale.* However, as all of these animals produce similar effects it perhaps is not of much practical moment to which species the harvest bug exactly belongs. Possibly the application of a solution of calcium chloride might relieve the intolerable itching, or the internal exhibition of the drug might obviate the effects of the bite, but for prevention the measures cited by Mr. Maude appear to be the only feasible methods of escape.—ED. L.

"THE DEGRADATION OF FOOD."

To the Editors of THE LANCET.

SIRS,—All readers of THE LANCET will recognise the services you render to the community by your unceasing attention to questions of public hygiene. But the sleepless watchman is apt at times to be deceived by his own vigilance, and an annotation in your issue of August 10th, p. 382, on "The Degradation of Food" seems to show that you have not altogether escaped this danger, as there probably never was a time at which the bulk of the people's food was so wholesome as it is at present. Your illustration on the subject of jam does not seem to me to be particularly happy. Home-made jam is certainly made without glucose, and every housekeeper knows how terribly apt home-made jam is to crystallize; lumps of sugar of the size of a bullet are frequently met with in the domestic jam-pot. The warning against roller-milled flour certainly comes rather late now that all the millers of this country have transformed their plant, but the main thing to note is that it really matters very little even if bread is slightly less nutritious than it used to be. There are very few people who eat much bread at the present day and this being so a slight falling-off in nutrition really amounts to nothing at all. Your complaint about the flavourless bread has certainly this much truth—that bakers are disposed to give too much attention to colour and not enough to flavour. But the diminished consumption of bread arises simply from the increased wealth of the people. Formerly a large proportion of the population lived chiefly upon bread because they could not afford to buy anything else. Times have changed since then and bread has lost a good deal of its importance. It has gone out as a necessity and it has yet to come in as a luxury. At the same time any resident in London or any large town can have the most palatable and perfect bread possible if he would only take the trouble to look for it. He may be certain of one thing, that housewives, now they have once been emancipated, will never again return to the bondage of home-baking.

I am, Sirs, yours faithfully,
EDITOR OF THE BAKER AND CONFECTIONER.
Chancery lane, London, August 14th, 1901.

⁂ The defence that modern conditions of life make substitution a necessity was to be expected. But the defence is unsatisfactory. Cane sugar crystallises, and therefore jam or marmalade cannot be made with it any longer. Would glucose be used in substitution if it cost three times as much as cane sugar? Of course it would not.—ED. L.

"FATAL INTESTINAL HÆMORRHAGE IN PNEUMONIA."

To the Editors of THE LANCET.

SIRS,—The very interesting paragraph on fatal intestinal hæmorrhage in pneumonia on page 460 of THE LANCET of August 17th might give the impression that pneumococcic colitis was not described in this country. Therefore it seems only fair to English medicine to point out that pneumococcic colitis will be found described on page 942 of the article "Diseases of the Colon" in vol. iii. of Allbutt's System of Medicine, published four years ago.

I am, Sirs, yours faithfully,
Harley-street, W., August 19th, 1901. W. HALE WHITE.

THE MEDICAL GUILD.

To the Editors of THE LANCET.

SIRS,—I have the honour to forward you the following resolutions which were unanimously passed at the last meeting of the Medical Guild, Manchester, on July 26th, as follows:—

(1) That in the opinion of the Medical Guild, seeing that vaccination is made compulsory in the interest of public health, the parent or guardian of a child should have the right to select any registered medical practitioner, who is willing to do so to perform the vaccination, and that the cost of the same should be defrayed by the State at a fixed rate.

(2) That, in the event of the foregoing resolution being passed, the Council be requested to consider what steps can be taken to influence future legislation on the subject.

I am, Sirs, yours faithfully,
Manchester, August 17th, 1901. DAVID OWEN.

THE STATISTICS OF DIPHTHERIA.

To the Editors of THE LANCET.

SIRS,—From time to time a communication is published drawing attention to the marked decrease in the death-rate which has followed the introduction of antitoxin. In looking over the 1899 report of the medical officer of health of the County of London a diagram showing the annual rate of deaths from diphtheria calculated per 1000 of the population, struck me forcibly in this connexion. It showed that for the last two years given, 1898 and 1899, this rate was almost identical with the actual mean rate of the last 40 years, while a table pointed out that the death rate calculated on the number of [illegible] to 14 in the last 10 years. [illegible] results raise questions which [illegible] of solution.

If we assume, as in the face of all the clinical evidence we are bound to assume, the inestimable value of the antitoxin treatment, we are met by the obvious difficulty that increased isolation (the Asylums Board hospitals now take 60 per cent. of all notified cases as against 30 per cent. previously), improved sanitary arrangements among the poorer classes, and increased efficiency of treatment have not prevented an outbreak of diphtheria which for purposes of comparison with previous years should be represented by a population death rate of 0·73 instead of 0·43. That is to say that if [illegible] of antitoxin and leave [illegible] former 23 per cent. no[illegible]fications of the years under examination would give 0·73 deaths per 1000 living, thus showing how formidable is the epidemic in question. If, on the other hand, we assume that the antitoxin treatment has only stimulated the powers of notification of the profession and has had no effect on the actual number of deaths we make a serious charge against the treatment. That charge receives very considerable support from the diagrams shown of Metropolitan Asylums Board hospitals. In the first is shown the ratio of deaths from diphtheria in hospitals to deaths from diphtheria in London, and in the second the ratio of admissions to notifications. Year by year for 10 years these ratios are almost identical. That is to say, that the introduction of antitoxin has not improved the treatment of cases in hospital as compared with the total cases in London. For example, in 1883 30 per cent. of the total cases notified were treated in hospital and 30 per cent. of the total deaths occurred there; in 1893 60 per cent. of the total cases notified were treated in hospital and 60 per cent. of the total deaths occurred there. Such a stimulation of notification as I have suggested would result in an increase of cases with no change in the number of deaths, the result statistically being a fall in the case mortality.

The three most potent factors in the spread or retardation of such a disease as diphtheria are isolation, sanitation, and aggregation. I propose to take as an example of each of these factors scarlet fever, enteric fever, and measles, and to compare the increase or decrease of the population death-rate of each. In none of these diseases has there been a radical alteration of treatment and the spread of each is regulated in the main by only one of these factors.

Table showing the Death-rate per 1000 of Living in various Diseases.

—	1899	Mean of period from 1888 to 1898	Mean of period of longer duration
Diphtheria	0·43	0·49	0·43
Scarlet fever ...	0·09	0·21	0·54
Enteric fever ..	0·17	0·13	0·19
Measles	0·47	0·62	0·58
Whooping-cough	0·38	0·54	1·49

On the face of it such a table would suggest that if any specific has been found it would not be for diphtheria, but for scarlet fever or whooping cough. First, as to scarlet fever, the population death-rate has gradually fallen from 0·21 to 0·09 per 1000; the case death-rate in the Metropolitan Asylums Board hospitals has fallen from 12·2 to 5·9 in the course of 23 years. If isolation has any effect on diphtheria it should, as in scarlet fever, reduce not only the case-rate but the population-rate *pari passu;* isolation has increased, as I pointed out previously, from 30 to 60 per cent. of the total number of cases. Secondly, as to enteric fever, the march of sanitation has reduced the population death rate from 260 per 1,000,000 to 130 per 1,000,000 in the course of 20 years; 1899 was a bad year and considerably above the average. Thirdly, as to measles, it has been asserted that this outbreak of diphtheria of such magnitude is due, in part at any rate, to the aggregation of children in board schools, and the fact that the proportion of notified cases within the school age (from three to 13 years) has increased in 10 years from 50·9 to 62·9 per cent. of the total notifications is adduced as evidence. We should expect therefore to find a similar rise in the population death-rate of measles. Measles is, of course, very variable in its incidence, but the table shows definitely that on the whole the aggregation of children has not increased the population death-rate from measles. We must also bear in mind that the number of children attending school increased during this period very considerably, and that at this period of life follicular tonsillitis is most common.

Hence we find in conclusion that a disease subject to fluctuations dependent on causes which have steadily produced a fall in the population death rate of other similar diseases, and further aided by a treatment which has almost halved the case mortality, has yet achieved the distinction of remaining steady at the mean population death rate of the last 40 years. There are two possible solutions of the difficulty: (1) antitoxin is a failure and the attention drawn to the disease has resulted in greater accuracy in notification; and (2) for some unknown reason a cause not acting on the like diseases had induced a widespread epidemic, modified by the antitoxin treatment. Which of these is the right interpretation time alone can tell us. Meanwhile we shall doubtless continue to notify and to inject as before, recognising that as far as statistics go antitoxin is still on its trial. I am, Sirs, yours faithfully,

DONALD F. SHEARER, M.B. Oxon., F.R.C.S. Eng.

Upper Richmond-road, S.W.

OBSERVATIONS ON THE ALTERNATE ERECTILITY OF NASAL MUCOUS MEMBRANE.

To the Editors of THE LANCET.

SIRS,—Every observer who is in the habit of examining the naso-pharynx with the rhinoscopic mirror has noticed that the mucous membrane covering the turbinated bones undergoes erectile changes at times. Strong cocaine solution is used to determine whether this is really erectility or inflammatory change. Actual inflammation or polypoid growths do not disappear after cocaine application. From personal experience, gained by passing my tongue into the naso-pharynx, I may assert that the mucous membrane of the nasal air-passages becomes alternately turgid and relaxed. Every man can satisfy himself by observing in his own body that air does not go in with equal freedom through both the nasal air-passages simultaneously; it blows through each nasal passage for an hour or so with clockwork-like regularity. The cause of obstruction in the free passage of air through one of the nasal passages is the turgidity of the mucous membrane covering the turbinated bones of that side. I know many individuals who can feel this turgidity like myself with their tongues. The mucous membrane of the obstructed side is felt to be hotter than that of the side through which the air blows freely. This erectility of the nasal mucous membrane has been well described by Dr. McBride in his valuable work on "Diseases of the Nose, Throat, and Ear." Sir T. Lauder Brunton also speaks of this erectility in his lectures on the action of drugs. He thinks that this erectility is necessary for warming the cold air going into the lungs. These writers, however, do not recognise or explain the phenomenon of this rhythmically alternate erectility of the nasal mucous membrane. Of course, we can trace the phenomenon to the vaso-motor influence presiding over the blood-vessels of the mucous membrane of the erectile side But the clockwork-like regularity with which the mucous membrane becomes turgid alternately on each side is a very remarkable feature which we cannot explain at the present state of our knowledge. I bring this fact to the notice of the scientific world because though unknown to the Europeans, as far as I have been able to ascertain from their published books, it was known to the ancient Hindus as early as in the Vedic period.

It will not be out of place here to say a few words on the art of passing the tongue into the naso-pharynx. When I showed to some of the professors of the Medical College, Calcutta, how my tongue goes into the naso-pharynx they thought that this power was something peculiar to my family. This is, however, not so; as I have already noted, it is an art which can be acquired by every man. There are different processes, the best and the safest of which is the one I am going to describe. The front part of the dorsum of the tongue is fixed to the hard palate and the lower jaw is lowered as far downward as practicable and raised alternately. This exercise lengthens the fibres of the tongue-muscles and at last, when by practice the tongue is sufficiently long, it can be easily passed into the naso-pharynx. The anatomical details as felt by passing the tongue into the naso-pharynx are as follows. The tip of the tongue can be made to rest on the under surface of the body of the sphenoid bone. The posterior border of the vomer can be distinctly felt in front and if the tip is made to enter through one of the posterior nares, the turgid mucous membrane of the obstructed side appears to be hot and swollen like an onion. The turgidity of the mucous membrane yields to the slightest pressure of the tip of the tongue but reappears, owing to its elastic nature, as soon as the pressure is removed. On the side through which air is passing the mucous membrane is not at all swollen or as warm as on the other side and the inferior and middle meatuses can be distinctly made out. The openings of the Eustachian tubes and other anatomical details are also clearly felt.

That the Hindus observed the phenomenon of alternate erectility as early as the Vedic period is corroborated by the names they used to describe the cycle of rhythmic erectility of the mucous membrane of each side of the nasal cavity. Thus it is said that when air blows through the left nasal air-passage with ease and the right air-passage is partially or completely blocked, it is an index of the prevalence of what in Vedic language is called *irha-narhi*. So, when air blows through the right nasal passage and the left one is blocked, the condition is designated to be the index of the prevalence of *pingala-narhi*. When air goes in with perfect freedom through both the nasal air-passages (this momentary condition obtains in the interval between the appearance of erectility on one side and the disappearance of it from the other), the condition is taken to indicate the prevalence of *susumna-narhi*. The ancient Hindus went so far as to observe that from the first three days after full moon air would be blowing through the right nasal air-passage during the first hour after sunrise; and the first three days after new moon air would be blowing in the left nasal air-passage during the first hour after sunrise. Then the reverse takes place in each case for three days and so on. Anybody may satisfy himself as I have done by trying to verify this observation. As all the observations I have noted were made in healthy subjects it is unnecessary to say that the law does not hold good in disease.

In conclusion, I venture to expect that scientific men of greater abilities than myself will take up and work out this important subject.

I am, Sirs, yours faithfully,

HEMCHANDRA SEN, M.D.,

Teacher of Materia Medica, Campbell Medical School, Calcutta,
Examiner in Anatomy, Calcutta University.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—Dr. Walter Kidd calls my attention to a letter published by him in *Nature* of August 8th. In it I find that he alludes to the correspondence which has been carried on under the above heading in THE LANCET and that he is good enough to inform the readers of *Nature* that "the greatest vigour of assertion and multitude of words, if not greater logic, rests with the advocates of the view that alcoholism is a selective influence of value in the evolution of man and ought not to be interfered with by legislation. The reasons for this startling contention are numerous, but the justification rests ultimately on the doctrine of Weismann carried to the bitter end—viz., that acquired characters are not inherited. I submit that if it can be shown that on no other than a Lamarckian interpretation of certain small phenomena is possible, something may be done towards making a breach in a somewhat dangerous citadel." Dr. Kidd's controversial methods lack directness. It would have been more effective had he demonstrated his opponents' lack of logic to the readers of THE LANCET instead of hinting at them to the readers of *Nature*.

Here is the proposition I am challenged to refute: "In man hair is entirely wanting on the ungual phalanges of his hand and foot, very rare on the middle phalanges of either foot or hand, and always present more or less on the first row of phalanges in both foot and hand." Man is "the child of the monkey." "The monkey possesses hair on all the phalanges. The young orang possesses hair like that of the lower monkeys—i.e., on all the phalanges of foot and hand, though on the two terminal phalanges of the hand the hair is worn down and quite bristly, even though the animal is quite young." Dr. Kidd supposes that because the monkey has hair on the terminal phalanges and man has not, the absence of hair on the latter is due to the wearing down of hair in the former. He thinks no other explanation possible and he asks me to refute this proposition. I had expected a task less easy. His hypothesis involves the assumption that the wearing down of hair on the ungual phalanges so affects the germs situated in the far-distant testicle or ovum that the organisms which spring from them tend to reproduce the peculiarity the parent acquired. Clearly we ought not to accept a hypothesis so wildly improbable unless it can be shown that none other is feasible. Doubtless man is the child of the monkey, but not of the present-day monkey. Presumably both man and modern monkey sprang from a common stock. Its descendants, *pace* Dr. Kidd, wore the hair down the ungual phalanges, but the monkey more than the man, since the monkey uses its foot as a hand. Will Dr Kidd explain how it happens that the modern monkey retains the hair whereas the man has lost his? The disappearance of hair on the ungual phalanges is only part of a general phenomenon. Hair has disappeared more or less completely from the whole of man's body except from his head, face, armpits, and pubes. What has caused the disappearance? The wearing down of the hair. Well, but how? By what? How on any theory of "wearing-down," or, indeed, on any theory of the transmission of acquirements, was the sharp line of demarcation produced between the hairy and the practically non-hairy regions of the head? What wore down the hair on the face of the woman but did not wear it down on the face of the man? What caused its disappearance on the trunk and limbs? Clearly some agent or agents other than transmission of acquirements were productive of the change.

Dr Kidd has challenged me to refute him and to the best of my ability I have done so. It is no part of my task to offer an alternative explanation. However, if he wishes I am quite prepared to do so. But in that case we shall have to enter into the mysteries of retrogression and sexual selection. Will Dr Kidd tell us who stated that "alcoholism was a selective agent of value in the evolution of man which ought not to be interfered with by legislation"? I stated that it *could* not be interfered with since under the ordinary conditions of civilised life every attempt to do so had resulted in vastly increased drunkenness. Most certainly I have never advocated the atrocious doctrine that drunkards should be permitted or encouraged to drink themselves to death. Readers of THE LANCET who have been interested in the present controversy will find this and kindred topics made clear in a volume[1] which will be published in a few weeks.

I am, Sirs, yours faithfully,

Southsea, August 20th, 1901. G. ARCHDALL REID.

"HAY FEVER: ITS REMEDY."

To the Editors of THE LANCET.

SIRS,—While in no way desirous to detract from the merit of the treatment of hay fever advocated by Dr Clement Dukes, one might reasonably suggest, in these days of accuracy, the advisability of a preliminary examination of the interior of the nostrils, if not before spraying, certainly before applying the galvano-cautery. But my object in writing is to say, as the result of personal experience, that extract of the suprarenal gland is very apt to decompose. It is possible that the preparation of adrenalin chloride in solution with normal sodium chloride may not be liable to this drawback, and on this point I am lacking in special knowledge; but, if only for convenience, I suggest the employment of the drug in fresh made solution from tabloids as is nowadays so general with hypodermics and antiseptics. I am, Sirs, yours faithfully,

London, August 19th, 1901. LENNOX BROWNE.

"WAS LUIGI CORNARO RIGHT?"

To the Editors of THE LANCET.

SIRS,—Dr Campbell's statement in his letter under the above heading in THE LANCET of August 17th, p. 487, that pappy food is a harmful diet for children can hardly pass without comment. Astounded by the dietary prescribed by an eminent authority on children's diseases (whose identity is immediately recognisable) he yet fails to suggest any other that might take its place. True, he bids us discontinue the use of pap, and give "any plain food provided it is of a kind which necessitates thorough mastication." The majority of foods which come in such a category strike me as being most indigestible. Should we substitute beef steak for the pounded meat to which Dr Campbell objects? Must bread be given dry, and the child's gums torn—for at the age of 10 months only the incisor teeth have appeared—by the rusk which we are warned against softening into pap? I have frequently seen babies of the poorer classes suffer from a severe fit of choking on attempting to masticate a crust given by a well meaning but ignorant mother.

It must be apparent to those who have had much to do with babies that it is wrong to attribute the presence of adenoids to an imperfect use of the jaws. During the first year of life the jaws and tongue are in almost perpetual movement; when not taking the breast or bottle the child sucks its fingers or "comforter," or champs so vigorously that its bib is quickly saturated with saliva. I would furthermore suggest that, as pap-feeding is adopted more systematically and to a later age by the better classes, one would expect to find among them a larger proportion of adenoids, whereas it is recognised that the disease more generally affects the children of the poor. We must surely have more evidence that pap feeding is wrong and more explicit directions as to new diet before we can abolish the system so carefully arranged by the well-known authority with whom Dr Campbell disagrees.

I am, Sirs, yours faithfully,

Balham, August 20th, 1901. T. B. SELLORS.

"AN IMPROVED METHOD OF PHOTOGRAPHING PATHOLOGICAL SPECIMENS."

To the Editors of THE LANCET.

SIRS,—Having for many years been interested in the uses of photography as an aid to the efficient pictorial representations of medical subjects I am glad to see Dr Ellie Prowse's note in THE LANCET of August 17th, 1901, p. 450, and though she describes therein the method for securing the best result with a fresh specimen, or with one which can be removed from its jar, yet it is only applicable to these conditions and would not be of service where it is desired to photograph a permanently mounted specimen in the ordinary round or oval museum jar.

For this condition after several experiments I found that the only satisfactory way was to immerse completely the jar in water contained in a large vessel or tank having dark-coloured, dull surfaced back, bottom, and sides and a plate glass front. With this tank the only source of reflection is the camera; this is prevented by covering it with the velvet focussing cloth, leaving the lens only showing. A description of a tank made to the above specification will be found in "The International Annual of Photography" for 1889, and this tank has proved so useful that it has been employed in the successful photography of many hundred pathological specimens, both fresh and preserved, and not, as originally intended, for mounted specimens only.

I am, Sirs, yours faithfully,

A. R. F. EVERSHED.

Great Winchester-street, E.C., August 20th, 1901.

"THE ELECTROLYTIC TRANSMISSION OF SULPHUR."

To the Editors of THE LANCET.

SIRS,—Having read Dr F. W. Smith's article on the Electrolytic Transmission of Sulphur through the Skin in THE LANCET of August 10th, p. 371, and having gathered the impression that he considers such transmission as a new discovery, I feel it incumbent upon me to state that the electrolytic transmission of sulphur and other medicinal agents through the skin has been known and practised by my friend E. Savary de Rovigo for more than 10 years in London. I am, Sirs, yours faithfully,

CHARLES J. NEPEAN LONGRIDGE.

St George's Hospital, S.W., August 15th, 1901.

GREY'S HOSPITAL, PIETERMARITZBURG.—In reference to the reorganisation of this hospital a petition to the Governor from the Pietermaritzburg Branch of the South African Medical Association has been received at the Colonial Secretary's Office, Pietermaritzburg, and we are informed that action is being taken with a view, if possible, to meet the wishes of the reformers.

CORNWALL CONVALESCENT HOME FOR MEN, PERRANPORTH.—The ninth annual report of this home, which was founded and endowed by Mr J. Passmore Edwards in memory of his mother, has been recently issued. It shows that during 1900 there were 101 patients admitted, the average stay in the home being 21 days, and the cost per patient being £2 12*s.* 2*d.* The financial statement showed a favourable balance of £116.

OBSERVATIONS ON THE ALTERNATE ERECTILITY OF NASAL MUCOUS MEMBRANE.

To the Editors of THE LANCET.

SIRS,—Every observer who is in the habit of examining the naso-pharynx with the rhinoscopic mirror has noticed that the mucous membrane covering the turbinated bones undergoes erectile changes at times. Strong cocaine solution is used to determine whether this is really erectility or inflammatory change. Actual inflammation or polypoid growths do not disappear after cocaine application. From personal experience, gained by passing my tongue into the naso-pharynx, I may assert that the mucous membrane of the nasal air-passages becomes alternately turgid and relaxed. Every man can satisfy himself by observing in his own body that air does not go in with equal freedom through both the nasal air-passages simultaneously; it blows through each nasal passage for an hour or so with clockwork-like regularity. The cause of obstruction in the free passage of air through one of the nasal passages is the turgidity of the mucous membrane covering the turbinated bones of that side. I know many individuals who can feel this turgidity like myself with their tongues. The mucous membrane of the obstructed side is felt to be hotter than that of the side through which the air blows freely. This erectility of the nasal mucous membrane has been well described by Dr. McBride in his valuable work on "Diseases of the Nose, Throat, and Ear." Sir T. Lauder Brunton also speaks of this erectility in his lectures on the action of drugs. He thinks that this erectility is necessary for warming the cold air going into the lungs. These writers, however, do not recognise or explain the phenomenon of this rhythmically alternate erectility of the nasal mucous membrane. Of course, we can trace the phenomenon to the vaso-motor influence presiding over the blood-vessels of the mucous membrane of the erectile side. But the clockwork-like regularity with which the mucous membrane becomes turgid alternately on each side is a very remarkable feature which we cannot explain at the present state of our knowledge. I bring this fact to the notice of the scientific world because though unknown to the Europeans, as far as I have been able to ascertain from their published books, it was known to the ancient Hindus as early as in the Vedic period.

It will not be out of place here to say a few words on the art of passing the tongue into the naso-pharynx. When I showed to some of the professors of the Medical College, Calcutta, how my tongue goes into the naso-pharynx they thought that this power was something peculiar to my family. This is, however, not so; as I have already noted, it is an art which can be acquired by every man. There are different processes, the best and the safest of which is the one I am going to describe. The front part of the dorsum of the tongue is fixed to the hard palate and the lower jaw is lowered as far downward as practicable and raised alternately. This exercise lengthens the fibres of the tongue-muscles and at last, when by practice the tongue is sufficiently long, it can be easily passed into the naso-pharynx. The anatomical details as felt by passing the tongue into the naso-pharynx are as follows. The tip of the tongue can be made to rest on the under surface of the body of the sphenoid bone. The posterior border of the vomer can be distinctly felt in front and if the tip is made to enter through one of the posterior nares, the turgid mucous membrane of the obstructed side appears to be hot and swollen like an onion. The turgidity of the mucous membrane yields to the slightest pressure of the tip of the tongue but reappears, owing to its elastic nature, as soon as the pressure is removed. On the side through which air is passing the mucous membrane is not at all swollen or as warm as on the other side and the inferior and middle meatuses can be distinctly made out. The openings of the Eustachian tubes and other anatomical details are also clearly felt.

That the Hindus observed the phenomenon of alternate erectility as early as the Vedic period is corroborated by the names they used to describe the cycle of rhythmic erectility of the mucous membrane of each side of the nasal cavity. Thus it is said that when air blows through the left nasal air-passage with ease and the right air-passage is partially or completely blocked, it is an index of the prevalence of what in Vedic language is called *irha-narhi*. So, when air blows through the right nasal passage and the left one is blocked, the condition is designated to be the index of the prevalence of *pingala-narhi*. [1] A Study in Heredity, by G Archdall Reid T Fisher Unwin

SANITATION AND SMALL-POX AT GLOUCESTER.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE anti-vaccinationists very generally allege that bad sanitation is the principal cause of small-pox. Consequently as Gloucester is a town where the anti-vaccinationists are exceptionally numerous it was natural to expect that particular attention would be given to sanitary matters, and that if, in spite of such action, small-pox did break out, then it would occur in those quarters where sanitary improvements had been least effective. It so happens, however, that the very reverse is the case. Though it would not be correct to denounce Gloucester as a particularly insanitary town it nevertheless cannot be said that any very special energy or exceptional concern has been displayed as regards dealing with the sanitary defects that do exist. Further and even more remarkable is the fact that perhaps the most effective sanitary measures that have been taken were followed, and not preceded, by the great small-pox epidemic. The drainage of the town is far from corresponding to the modern ideal of self-cleansing sewers. The existing system of sewerage for the city of Gloucester was commenced in 1852 and then the sewers were not only built in view of the future extension of the boundaries of the city but were exceptionally well constructed. Indeed, their construction was quite in advance of the times, though doubtless it may now be found that they do not correspond with the modern ideal. Then when, in 1875, the boundaries were extended the older system was connected with more modern but very inferior sewers that had been built by small local outlying authorities. Since then many of these sewers have been relaid and otherwise improved. That the system did not work well is proved by the fact that very bad odours escaped from the man-holes and occasioned many complaints. It was not till ten years later that this nuisance was finally removed. By that time 600 ventilating shafts had been put up. How far this may be considered a radical remedy is open to question. If the 600 shafts increased the amount of ventilation in the sewer then the evil would be lessened, and doubtless this was the case. But if not, then they only removed the nuisance to an altitude where it would not be perceived by people walking in the streets, but where it would be more likely to penetrate the bedrooms of the houses. As, however, I failed to find any record of complaints from the inhabitants of such bedrooms it is most likely that the shafts so stimulated the ventilation of the sewers that the air inside the sewers had not time to become impregnated with foul odours. Though this is an undoubted improvement, still it does not show that the sewers are in themselves all that can be desired.

There are in Gloucester three main collectors. The northern outfall sewer is 3433 yards in length. It commences with a 9-inch pipe and ends in a sewer measuring 4 feet 6 inches by 3 feet. The fall is 1 in 178. The central outfall sewer is 3000 yards in length and of the same size, but the fall is only 1 in 209. These drain the older parts of the town. They travel along the two sides of a circle and meet at the outfall, where they discharge their crude sewage into a narrow branch of the river Severn. This outfall is as the crow flies within some 500 yards of the Cathedral and the centre of the old town and above a weir which is situated at a short distance lower down the river. It is most important to note that this is a tidal river and, therefore, at flood times the sewage is forced back up the sewer, propelling also the sewer gases back into the town. This is so obvious a defect that in granting leave to extend the boundaries of the city the Local Government Board especially stipulated that these two sewer outlets should be abolished and the sewage discharged lower down the river beyond the weir. So far nothing whatsoever has been done to carry out this instruction. There are many material difficulties in the way. In the meanwhile and in spite of the more energetic ventilation of the sewers I am told that bad odours are still noticed when the sewer is tide-locked. The system of ventilation is that of utilising the man-holes which theoretically serve as air inlets, the ventilation shafts being in connexion with these man-holes. Sometimes, however, the current is reversed and the sewer air then comes out of the man-holes and on the street level. In that case I should imagine that the air descending the ventilating shaft scarcely penetrates the sewer but that the greater part comes out with the sewer air into the street, which it serves to dilute at the critical point of discharge into the street.

The third and southern outfall is much further from the town and below the weir, but this delivers only about a quarter of the total sewage of the town, and it is also thrown into the river in its crude condition. That three-quarters of the crude sewage should be discharged into a narrow branch of the river Severn as it passes by the north-western portion of the town, and at a point where its flow onwards must to some extent be impeded by a weir that is further down the river, undoubtedly constitutes a grave sanitary defect. Then the portion of the city nearest to this outfall is the oldest and the most overcrowded part of Gloucester. Here dwell some of the poorest inhabitants and we find the nearest approach to what might be qualified as slums. Under these circumstances it would be natural to suppose that if the great small-pox epidemic was due to bad sanitation the greatest number of victims would be living near to the water-logged portion of the sewers or where poverty and density of population were most accentuated. It is highly significant that the reverse was the case. To begin with, Gloucester has been remarkably free from drain water-borne diseases such as typhoid fever and diarrhœa. Instead of the north-western it was the south-western districts that suffered most. The density of population in the parts affected amounted to only 31·41 persons per acre. In the districts that were not affected there was a much larger population, amounting in one part to 64·3 persons per acre. Old houses, some of them thickly populated, with bad or at least inferior drains, existed in those parts of the city which completely escaped from the epidemic. But in the district affected the houses were all new and for the most part consisted of semi-detached villas. Therefore there were many gardens, plenty of fresh air, a higher state of well-being, and much less poverty and dirt than in the parts of the city where the epidemic did not spread. Thus the experience acquired at Gloucester does not at all confirm the theory that bad sanitation is the principal cause of small-pox. Indeed, if we are to judge men's beliefs by their actions, it does not seem as if the inhabitants of Gloucester had very much faith in this theory of the anti-vaccinationists, for they displayed no very great desire to secure the best sanitary conditions. Thus, for instance, they would not listen to the supplications of their medical officer of health when he urged upon them the necessity of having a disinfecting stove. That there should be some hesitation to burden the town with the expense of a vast scheme of drainage or other sanitary improvements can well be understood and excused. But the expense of a proper disinfecting stove and station involves only a trivial outlay. Nevertheless, a disinfecting stove was not purchased until after there had been many cases of small-pox and the authorities had realised that it would cost less to disinfect than to burn the infected clothing, bedding, &c.

The history of the small-pox epidemic has often been told. It is not necessary to repeat this well-worn story. Full details were given, notably in a paper read by the medical officer of health of Gloucester, Dr. John Campbell, to the Incorporated Society of Medical Officers of Health on March 19th, 1897. It will suffice to recall that Dr. Campbell then stated that there had been in all 1981 cases of small-pox. In analysing these figures he showed that the attacks of small-pox in properly vaccinated children were extremely rare up to the age of 10 years; that such cases as did occur under these conditions were not severe, and that deaths were almost unknown; but very few of the unvaccinated escaped when exposed to infection and then the mortality was very great; also none of the nurses contracted the disease, but they had all been properly vaccinated and revaccinated. It certainly seems as if the most effective measure taken to check the spread of the disease was vaccination; and it was interesting to note how rabid antivaccinationists promptly resorted to vaccination when they found that the danger was at their door. Dr. Campbell relates that the proprietor of the local daily paper (which waged ceaseless war against vaccination), who he believes was chairman of the local branch of the Anti-vaccination League, took good care to have himself vaccinated. It was this inconsistency, widely shared by the public at large, that finally saved the town. Had the epidemic been due to bad sanitation it would not have ceased so promptly, nor would it have spread so rapidly. Indeed, no important alterations were made in the town that could account for the cessation of the epidemic. The patients could not even be isolated, for the isolation hospital only contained 16 beds, and though huts were hastily constructed they could not be built in time, nor were they sufficiently numerous to accommodate the majority of cases; thus only 742 cases were received in the hospitals out of the 1981 cases.

In conclusion, it may be said that in sanitary matters Gloucester cannot be qualified as a model city, but it cannot be denounced as being in an especially unsanitary condition. Like most towns it has its good and bad points, but the bad points had nothing to do with the epidemic, for it was precisely the districts they affected that escaped from small-pox.

Gloucester, August 20th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Precautions during Epidemics.

THE prevalence of continued hot weather brings in its train certain consequences. These might be largely preventable if only precautions were taken at the right time and an element of prudence and common sense was kept in reserve. In the weekly return of the medical officer of health of the city the total number of 92 deaths from zymotic diseases are recorded, of which 78 were from diarrhœa. This is a large number in a short interval and calls for comment as to the cause. The medical officer issues bills pointing out the precautions to be taken during the existence of the prevailing epidemic, but it is to be feared that these are seldom read, and still less often acted upon. Yet the mortality might be greatly reduced if these simple rules were followed. The injudicious feeding of infants and the indifference and carelessness associated with the bringing up of young children in big towns are the chief factors of so large a death-roll. Until a sense of responsibility can be instilled into the minds of the parents the advice of the Health Committee and the admonitions of the coroner are but as sounding brass and a tinkling cymbal.

The Dangers of the Brass Trade.

Birmingham owes a great part of its commercial success to the number of industries connected with the metal trade. Among these stand out prominently the various manipulations with brass, polishing being a fertile source of mischief from the dust produced. It is stated that the workmen object to the use of respirators during their work, that they often take their meals in the same room as that in which the work is done, and that they show a disinclination to wash their hands at any time during or after the process. An inquest was recently held on the body of a brass worker, aged 28 years, in which the medical evidence disclosed how frequently illness is engendered by this kind of work. It was shown that certain symptoms were common among this class when affected by the work in which they were engaged, such as pallor, discolouration of the teeth and gums, abdominal pain, vomiting in the morning, metallic taste in the mouth, night sweats, and general weakness, while inflammation of the stomach was usually present. It was also wisely pointed out that free ventilation, the use of respirators, and periodical medical examination of the workmen would go far towards mitigating the spread of the diseases which are caused by this kind of work. The inspector of factories explained that a special Government inquiry was made a few years ago and that certain rules were drawn up for those working in brass-casting shops, but that these could not be enforced in those where polishing only was done. The coroner observed that the attention of the Home Office should be called to the matter and promised to make a representation in that quarter.

Analysts' Certificates.

A case of much interest to dispensing chemists was recently brought before the Birmingham Police-court. A sample of compound tincture of benzoin was said to be below the standard of the British Pharmacopœia. The case was adjourned in order that the sample might be sent to the Government laboratory. [illegible]
was at variance with that of
the city; the bench therefore

was entitled to a discharge. Evidently opinions differ on what might well be looked upon by outsiders as matters of fact.

Vacation Difficulties.

The universality of August as a holiday month causes great trouble in finding substitutes for official work or private practice. As much as six guineas a week is being offered without success for a locum-tenent to take duty during the absence of a principal.

August 20th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Seamen's Hospital.

AT a meeting of the committee held on August 13th it was stated that the estimated cost of the new hospital was £30,000. Towards this sum £13,159 have been already received and a further sum of £3597 has been promised. The trustees of the late Marquis of Bute will contribute £13,242, and if the above-mentioned promised subscriptions are not received by the committee, the trustees will make good the deficiency.

Monmouthshire County Council.

At the meeting of the Monmouthshire County Council held on Aug. 7th a report was presented by the chairman of the Sanitary Committee upon the sanitary condition of the county, being, in fact, a digest of the annual reports of the district medical officers of health. The population of the administrative county at the last census was 230,000, an increase of 27,000 during the past decade. This is not a large population nor is the increase very great compared with other counties, but there are in Monmouthshire a large number of rapidly increasing colliery villages and many of them are in anything but a satisfactory state as regards water-supply, drainage, and the housing of the inhabitants. The county council appears to be quite aware of the circumstances connected with these villages, and one member regretted that the powers of the council were merely advisory—an extraordinary statement in view of the fact that the council possesses very ample powers as regards the provision of isolation hospitals and the prevention of the pollution of rivers. The district councils would, no doubt, attach greater weight to the recommendations of the Sanitary Committee if the county council would itself exercise its own powers—not the least of which is the appointment of a county medical officer of health, a duty which the council has persistently refused to perform.

The New Dietary at Bristol Workhouse.

When the Bristol Board of Guardians were discussing early in the present year the adoption of the new dietary for the workhouse inmates it was anticipated that the change would certainly involve an increased annual charge. The report for the first three months ending midsummer last during which the new dietary has been in operation shows that not only has there been no increase in the expenditure, but that an actual saving has occurred. At the Stapleton Workhouse there was a saving of £130 compared with the corresponding quarter of 1900. It is true that there were slightly fewer inmates in 1901; on the other hand, at the Eastville workhouse, where the number of inmates was greater than in 1900, the expenditure was £10 less.

August 19th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Presentation to an Aberdeenshire Medical Man.

ON August 14th Dr. James Wilson, of Old Meldrum, Aberdeenshire, was presented with a silver fruit-bowl and a purse of 100 sovereigns. The bowl bears the following inscription: "Presented to James Wilson, Esq., M.D., along with a purse of sovereigns by more than 400 subscribers, in grateful recognition of the exceptional skill, unfailing kindness, and unswerving fidelity with which he laboured among them for over 40 years. Old Meldrum, August, 1901."

Aberdeen Medical Officer's Report for 1900.

The annual report by Professor Matthew Hay, medical officer of health of the city of Aberdeen, for 1900 has just been issued. It deals with a wider range of subjects than usual. The population is given as 150,906. Professor Hay remarks that the death-rate (19·0 per 1000) is not high for a town of the size of Aberdeen and is indeed lower than in the majority of towns with a corresponding population. The death-rate from diphtheria, influenza, phthisis, pneumonia, &c., was in each case above the average, while the rate from measles, scarlet fever, typhoid fever, &c., was found to be on the decrease. The mortality among infants has increased materially since 1866. The total number of cases of infectious disease was 6140 and the number of deaths 196, or 3·2 per cent. of total mortality from all causes. The report deals at great length with the question of vaccination and revaccination. Professor Hay also says that the sanitary state of the town was generally good, the bakehouses had all been inspected in the course of the year and were on the whole in a satisfactory condition, and adds remarks directing attention to "the harmful and even vicious habit of cigarette smoking among young boys." In comparing Aberdeen with the other large towns of Scotland, says Professor Hay, and taking account of the alterations in the estimated populations brought about by the recent census, it will be observed that the birth-rate and marriage-rate of Aberdeen were among the highest, while the death-rate was among the lowest. During the year 762 patients were admitted into the City Hospital, the great bulk of the patients suffering from measles or scarlet fever. The mortality-rate for each disease was, with the exception of measles, gratifyingly low. In the case of measles the rate (2·6 per cent.) was above the average, but this was in large measure due to an outbreak of measles in an institution where a number of the children attacked were already suffering from other serious ailments.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Central Pathological Laboratory in Connexion with the Lunatic Asylums of Ireland.

THE proposal for the foundation of a central pathological laboratory for the investigation of mental disease has recently taken a practical shape by the insertion of a permissive clause in the Lunacy Bill which has just passed. According to it the committees of any two or more district asylums may, with the consent of the county council, agree to unite "in providing and maintaining a laboratory for pathological research in connexion with insanity and nervous diseases," and the committees of those institutions may defray the expenses incurred in connexion with their union for the purpose of helping pathological research. It will be remembered that in January last a deputation representing the Royal Academy of Medicine in Ireland and the Irish division of the Medico-Physiological Association of Great Britain and Ireland waited on the Chief Secretary with reference to the project of establishing a central laboratory in Dublin. Sir Christopher Nixon—a member of the deputation—remarked that such research laboratories existed in London and in Edinburgh, while Professor Cunningham stated that a sum of £600 a year would probably be sufficient for the purpose in Ireland as it has proved to be in Scotland.

The Royal Commission on University Education in Ireland.

The Royal Commission on University Education in Ireland have arranged to commence their sittings in Dublin about the middle of September (the Senate of the Royal University at their last meeting having granted the use of their buildings to the Commission). It is stated in the public press that in order to be possessed of as much statistical information as possible regarding the present condition of education in Ireland blank forms or query sheets have been sent to the heads of colleges and schools in various parts of Ireland to be filled up with the information required under the various heads, and some of these queries are certainly peculiar. The terms of reference to the Commission are "to inquire into the present condition of the higher, general, and technical education available in Ireland outside Trinity College, Dublin, and to report as to what reforms, if any, are desirable in order to render that education adequate to the needs of the Irish people." Now one of the returns sent out to be filled up by the heads of intermediate schools, is "with reference to the number of students from above school who proceeded to Trinity College, Dublin, and the Royal University of Ireland in the year 1900." As put by one of the Irish papers, if at the very outset of its proceedings the Commission brings in Trinity College in this way how are the Commissioners to draw the line when evidence is subsequently offered? Then among many true friends of education great surprise has been expressed at another query sent out by the authority of the Commission, asking those to whom the forms are addressed to state, if students are of various denominations, the number belonging to each. To introduce sectarianism so early into the proceedings of the Commission—before any evidence is heard—has aroused among many the suspicion that a determined bias is to be given, even at the very beginning, to the evidence to be tendered at the Commission.

Ambulance Work in Belfast.

Last week the annual inspection took place of the members of the Belfast Fire Brigade, who do so well the ambulance work of the city. The inspection was made by Lieutenant-Colonel C. J. Trimble, L.R.C.P., deputy-commissioner in charge of the north-western district. Forty-five men took part in the display and it came out that Belfast was the only place in Ireland where the presence of the inspecting officer was needed. It is a pity that the example set by Belfast in regard to ambulance work is not followed by other Irish towns. There are now three ambulance wagons in connexion with the Belfast Fire Brigade and last year they were called on 1817 times.

Lunacy in Ireland.

From the fifteenth annual report on the condition and management of lunatics and lunatic asylums throughout Ireland during 1900 I gather that there was a total increase of 306 cases of lunacy, being 253 less than that for the previous year, when 559 cases were reported. The increase was mainly in district asylums—495. The increase in private asylums was 10, while in workhouses there was a decrease of 184. The general increase was 186—less than the average for the past 10 years, which was 462. The figures for 1900 show an increase in district asylums of over 41 per cent. as compared with 1881. As showing the growth of lunacy in Ireland it may be said that the number of insane under care has increased from 250 per 100,000 of the population in 1880 to 470 per 100,000 in 1890.

Overcrowding in Donegal Asylum.

At a meeting of the Committee of Management of this asylum held on August 14th Dr. E. E. Moore, the resident medical superintendent, reported that there were at present in the institution 404 males and 215 females, that is, 619 in all, while the legitimate accommodation was for 322 males and 198 females, or 520 in all; so that there are 99 patients resident in the asylum in excess of accommodation. The excess on the male side was 82 and on the female side 17, so that the numbers were slowly but steadily increasing. All the dormitories were overcrowded, and in the corridors where beds could be put up they were full. These corridors were meant to act as ventilating shafts for the asylum, but owing to patients sleeping in them they were shut at night, and the consequence was that the ventilation of the asylum was seriously interfered with and in the long run the health of the inmates would suffer. The whole question of how to provide increased accommodation is to be considered at the next meeting of the committee.

The Royal University Graduates' Association.

The executive of the Royal University Graduates' Association have issued a circular to the graduates of the Royal University pointing out that a crisis has been reached, as it will soon be settled whether university education in Ireland is to be free and untrammelled, as in all civilised countries, or to be guided and directed by small political and ecclesiastical coteries. It is pointed out that some members of the senate would destroy the Royal University and instead of protecting would sacrifice the interests of the graduates, their policy being to carve the Royal University into two petty ones which would be only local and sectional, and which could hardly be expected to attain to any repute. It is advised that the most strenuous resistance should be offered to such a retrograde policy, and that should this end in failure there is still an alternative for the graduates, that is, to send their sons and daughters to England and to Scotland where they will receive the very best education in colleges and universities of good repute, of certain stability, and free from the narrowing influence of sectarianism The association opposes, they say, Mr Balfour's scheme of a university for the Roman Catholics and a university for the "great Presbyterian bodies of the North not through hostility to any Church whatever, but on the ground that higher education could never thrive in institutions founded not on broad educational principles, but virtually to satisfy ecclesiastical demands and to meet political exigencies Graduates who approve of this policy are asked to become members of the association.

PARIS

(FROM OUR OWN CORRESPONDENT)

The Medico Pharmaceutical Association at Lille and the Pasteur Institute

THE law courts at Lille have this week had to decide a dispute of considerable interest and the decision arrived at gives a promise of future developments which are not likely to be lacking in this quality The Pasteur Institute of Lille presided over by Dr Calmette and founded by the proceeds of a public subscription to which he was the most liberal contributor, commenced last year a campaign against tuberculosis in the North of France and established sanatoria as well as dispensaries in which medical advice was given *gratis* The medical men of the district resented these proceedings, for they thought that the great reputation of the institute would attract patients who would thereby be lost to them, or at least that the practitioners selected from among them to attend the patients at the dispensaries would from this circumstance acquire a position in the eyes of the public which would benefit them to the detriment of the rest The medical men of Lille said that they had contributed as ordinary citizens to the fund which established the institute and that it was intended solely for scientific work and not for the practice of medicine or pharmacy in competition with the professional men of the town The pharmaceutical chemists joined the medical men in this protest complaining that the public purchased sera from the Pasteur Institute and that it had given up a portion of its premises to an establishment for the manufacture of sterilised aerated waters from the preparation of which it made a profit A combination was formed by a great many medical men and pharmaceutical chemists in Lille to restrain the Pasteur Institute from carrying on a business by receiving paying patients and by selling sera otherwise than wholesale and to pharmaceutical chemists The result of this combination was the founding of a medico pharmaceutical association constituted in accordance with the conditions prescribed by the French law for professional associations (*syndicats*)—namely, by delivering a declaration of foundation to the prefect of the department. The association has now been in existence for three months which amounts to an official authorisation for the period during which the prefect may issue an interdiction is by law limited to one month It had collected funds, had organised conferences and was going to bring an action at law when it received notice from the authorities that the Minister of Justice had declared the association to be illegal and that proceedings would be taken if it was not dissolved The point raised against the association was that the law only authorised associations among persons of the same occupations or professions and that the Minister considered that medicine and pharmacy were not in this relation to one another The association obtained an opinion from a professor in the Faculty of Law at Lille and on being assured that its constitution was perfectly legal and that the threatened proceedings were an attempt at intimidation by the Minister probably instigated by the eminent personages who protect the Pasteur Institute it refused to dissolve and allowed itself to be prosecuted Judgment has just been delivered and the medical men have to congratulate themselves on persevering in their original policy The judges have decided in their favour by recognising the legality of the Medico Pharmaceutical Association and by declaring that medicine and pharmacy possess the mutual relations required by law for associations of mixed composition The association will therefore be in a position to go on with its projects and to persevere with its attack on the Pasteur Institute

Legal Responsibility of Hospital Officials

The Eleventh Chambre du Tribunal Correctionel has passed sentence on Mdlle Leullier under nurse, Mdme. Gauthier, nurse (*surveillante*) and M Faure, superintendent of the Hôpital Lariboisière They were all charged with wounding and homicide by imprudence On April 6th last Mdlle Leullier by a lamentable mistake took from a cupboard a jar of chloride of zinc instead of a jar of honey and glycerine and she gave six patients enemata containing a corrosive disinfectant and not the emollient which she supposed she was administering Two patients died, the others have not yet recovered This was the mistake which led to the prosecution M Faure the superintendent has been sentenced to 15 days imprisonment and 300 francs (£12) fine Mdme Gauthier to two months' imprisonment, and the under nurse to three months imprisonment They have all benefited by the system of respite which exists in France and which permits the non fulfilment of sentences except in case of a subsequent conviction These sentences even with this respite are regarded by the press as being very heavy It is asked why sentences of imprisonment were passed As a matter of fact there were extenuating circumstances and the court mentioned them in pronouncing judgment The jar of chloride of zinc was red as was also the jar of honey and glycerine and its label was almost illegible Moreover, the unhappy young woman who committed the mistake was overworked The sentence stated that her duties were excessive since she had to work 15 and even 18 hours a day, for which she was paid 42 francs (£1 14s.) a month The sentence recognised that the superintendent had a difficult task and a great deal to do but added that it was necessary for him to give personal attention to everything and that he would be unworthy of his position if he relied on his subordinates only exercising his authority from a distance

Biological Research Fund

Legal authority has just been given for the creation of a fund for scientific research It is divided into two sections and its object is the promotion of purely scientific work relative (1) to the discovery of new methods of treatment of the diseases which attack man, domestic animals, and cultivated plants, and (2) to the discovery apart from the medical sciences of the laws which govern natural phenomena (mechanics astronomy, natural history physics and chemistry) The income of the fund will be derived from the following sources 1 Grants made by the Government, by the departments, by the communes, by the colonies and by other sections of the population 2. Gifts and bequests 3 Individual or collective subscriptions 4 Grants deducted from the portion of the proceeds of the *pari-mutuel* assigned to philanthropic or charitable purposes locally, the annual amounts of these grants, which will not be less than 125 000 francs (£5000) will be fixed each year on the application of the council of management by the special commission held at the Ministry of Agriculture. 5 Interest of money invested in Government securities or deposited with the Treasury The fund is subject to the authority of the Ministry of Public Instruction It is managed by a council assisted by a technical commission concerned with the grants The first section which is the only one that interests medical men has to do with researches having for their object the promotion of the biological sciences and especially the discovery of new methods of treating the diseases of mankind, of the domestic animals, and of cultivated plants

Obituary

Dr Leroy de Méricourt who has just died at the age of 75 years was noted as one of the reorganisers of the French naval medical service He distinguished himself in the Crimea and was formerly Professor at the Naval Medical School of Brest He wrote much upon tropical medicine and hygiene and founded a review which is highly esteemed at the present day the *Archives de Médecine Navale* He was a member of the Academy of Medicine and Chevalier of the Legion of Honour

The Royal University Graduates' Association.

The executive of the Royal University Graduates' Association have issued a circular to the graduates of the Royal University pointing out that a crisis has been reached, as it will soon be settled whether university education in Ireland is to be free and untrammelled, as in all civilised countries, or to be guided and directed by small political and ecclesiastical coteries. It is pointed out that some members of the senate would destroy the Royal University and instead of protecting would sacrifice the interests of the graduates, their policy being to carve the Royal University into two petty ones which would be only local and sectional, and which could hardly be expected to attain to any repute. It is advised that the most strenuous resistance should be offered to such a retrograde policy, and that should this end in failure there is still an alternative for the graduates, that is, to send their sons and daughters to England and to Scotland where they will receive the very best education in colleges and universities of good repute, of certain stability, and free from the narrowing influence of sectarianism The association opposes, they say, Mr Balfour s scheme of a university for the Roman Catholics and a university for the "great Presbyterian bodies of the North" not through hostility to any Church whatever but on the ground that higher education could never thrive in institutions founded, not on broad educational principles but virtually to satisfy ecclesiastical demands and to meet political exigencies Graduates who approve of this policy are asked to become members of the association.

The Medico Pharmaceutical Association at Lille and the Pasteur Institute

THE law courts at Lille have this week had to decide a dispute of considerable interest and the decision arrived at gives a promise of future developments which are not likely to be lacking in this quality The Pasteur Institute of Lille presided over by Dr Calmette and founded by the proceeds of a public subscription to which he was the most liberal contributor commenced last year a campaign against tuberculosis in the North of France and established sanatoria as well as dispensaries in which medical advice was given gratis The medical men of the district resented these proceedings for they thought that the great reputation of the institute would attract patients who would thereby be lost to them or at least that the practitioners selected from among them to attend the patients at the dispensaries would from this circumstance acquire a position in the eyes of the public which would benefit them to the detriment of the rest. The medical men of Lille said that they had contributed as ordinary citizens to the fund which established the institute and that it was intended solely for scientific work and not for the practice of medicine or pharmacy in competition with the professional men of the town The pharmaceutical chemists joined the medical men in this protest complaining that the public purchased sera from the Pasteur Institute and that it had given up a portion of its premises to an establishment for the manufacture of sterilised aerated waters from the preparation of which it made a profit A combination was formed by a great many medical men and pharmaceutical chemists in Lille to restrain the Pasteur Institute from carrying on a business by receiving paying patients and by selling sera otherwise than wholesale and to pharmaceutical chemists The result of this combination was the founding of a medico pharmaceutical association constituted in accordance with the conditions prescribed by the French law for professional associations (*syndicats*)—namely, by delivering a declaration of foundation to the prefect of the department The association has now been in existence for three months which amounts to an official authorisation for the period during which the prefect may issue an interdiction is by law limited to one month It had collected funds had organised conferences and was going to bring an action at law when it received notice from the authorities that the Minister of Justice had declared the association to be illegal and that proceedings would be taken if it was not dissolved The point raised against the association was that the law only authorised associations among persons of the same occupations or professions and that the Minister considered that medicine and pharmacy were not in this relation to one another The association obtained an opinion from a professor in the Faculty of Law at Lille and on being assured that its constitution was perfectly legal and that the threatened proceedings were an attempt at intimidation by the Minister probably instigated by the eminent personages who protect the Pasteur Institute it refused to dissolve and allowed itself to be prosecuted Judgment has just been delivered and the medical men have to congratulate themselves on persevering in their original policy The judges have decided in their favour by recognising the legality of the Medico Pharmaceutical Association and by declaring that medicine and pharmacy possess the mutual relations required by law for associations of mixed composition The association will therefore be in a position to go on with its projects and to persevere with its attack on the Pasteur Institute

Legal Responsibility of Hospital Officials

The Eleventh Chambre du Tribunal Correctionel has passed sentence on Mdlle Leullier under nurse Mdme. Gauthier, nurse (*surveillante*) and M. Faure, superintendent of the Hôpital Lariboisiere. They were all charged with wounding and homicide by imprudence On April 6th last Mdlle Leullier by a lamentable mistake took from a cupboard a jar of chloride of zinc instead of a jar of honey and glycerine and she gave six patients enemata containing a corrosive disinfectant and not the emollient which she supposed she was administering Two patients died , the others have not yet recovered This was the mistake which led to the prosecution M Faure the superintendent, has been sentenced to 15 days imprisonment and 300 francs (£12) fine Mdme Gauthier to two months' imprisonment and the under-nurse to three months' imprisonment They have all benefited by the system of respite which exists in France and which permits the non fulfilment of sentences except in case of a subsequent conviction These sentences even with this respite are regarded by the press as being very heavy It is asked why sentences of imprisonment were passed As a matter of fact there were extenuating circumstances and the court mentioned them in pronouncing judgment The jar of chloride of zinc was red as was also the jar of honey and glycerine and its label was almost illegible Moreover, the unhappy young woman who committed the mistake was overworked The sentence stated that her duties were excessive since she had to work 15 and even 18 hours a day, for which she was paid 42 francs (£1 14*s*) a month The sentence recognised that the superintendent had a difficult task and a great deal to do but added that it was necessary for him to give personal attention to everything and that he would be unworthy of his position if he relied on his subordinates only exercising his authority from a distance

Biological Research Fund

Legal authority has just been given for the creation of a fund for scientific research It is divided into two sections and its object is the promotion of purely scientific work relative (1) to the discovery of new methods of treatment of the diseases which attack man, domestic animals and cultivated plants , and (2) to the discovery apart from the medical sciences of the laws which govern natural phenomena (mechanics astronomy, natural history physics and chemistry) The income of the fund will be derived from the following sources 1 Grants made by the Government, by the departments, by the communes by the colonies and by other sections of the population 2. Gifts and bequests 3 Individual or collective subscriptions 4 Grants deducted from the portion of the proceeds of the *pari mutuel* assigned to philanthropic or charitable purposes locally , the annual amounts of these grants which will not be less than 125 000 francs (£5000) will be fixed each year on the application of the council of management by the special commission held at the Ministry of Agriculture 5 Interest of money invested in Government securities or deposited with the Treasury The fund is subject to the authority of the Ministry of Public Instruction It is managed by a council assisted by a technical commission concerned with the grants The first section, which is the only one that interests medical men has to do with researches having for their object the promotion of the biological sciences and especially the discovery of new methods of treating the diseases of mankind of the domestic animals and of cultivated plants

Obituary

Dr Leroy de Méricourt who has just died at the age of 75 years was noted as one of the reorganisers of the French naval medical service He distinguished himself in the Crimea and was formerly Professor at the Naval Medical School of Brest He wrote much upon tropical medicine and hygiene and founded a review which is highly esteemed at the present day the *Archives de Médecine Navale* He was a member of the Academy of Medicine and Chevalier of the Legion of Honour

NEW YORK

(FROM OUR OWN CORRESPONDENT)

A Census of Lepers

A COMMISSION selected from the Marine Hospital Service, has been working under Congressional authority since 1899 making a scientific investigation of the extent of leprosy in America. They have sent circular letters to physicians, health officers, hospital superintendents, and others, in 600 localities covering the entire country, asking for reports and information regarding leprosy patients. Eight thousand of these circulars have been sent out, but only 2000 were answered. From these 277 lepers have been located, and their names and addresses obtained; 100 of these are known to live in New Orleans, and many of them are well to do and of good family. In Minnesota about 20 cases are reported, mostly Scandinavians living in the rural districts; seven cases were reported from New York, three from Chicago, and 15 from San Francisco, 12 of these being confined in the pest-house. In North Dakota there were 15 and but two in South Dakota: in New Mexico there were at least a dozen, and Baltimore reported three; the remainder were scattered throughout the country. As the circulars have brought but few replies comparatively and suspicious districts make no returns the commissioners believe that only about one-fourth of the cases have been reported. It is evident from this investigation that notwithstanding the widespread distribution of leprous patients throughout this country, and their increase in the last decade, there is no cause for alarm, for the disease is not so fatal, or so contagious, or so easily transmitted as tuberculosis. It has also been shown that cures have often been accomplished after two years' treatment. The commission will probably recommend to Congress that national lazarettes should be established in various parts of the country, one perhaps in New Orleans, one in New Mexico, and another in Minnesota or Montana A generous appropriation will be asked for, sufficient to cover the erection of fine isolated buildings with every appointment for the comfort and pleasure of the sufferers.

Bureau of Food Inspection in the Department of Agriculture.

Mr. B. F. Van Valkenburgh of Brooklyn, for 12 years assistant dairy commissioner and assistant commissioner of agriculture of New York, has just been appointed inspector of dairy exports for this port; the appointment was made und[illegible] Mr. H. E. Alvord, chief of the dairy division of the Bur[illegible] of Animal Industry. An appropriation of $1,500,000 [illegible] made by the last Congress for the use of the Secreta[illegible] Agriculture as a fund for the establishment of a [illegible] connexion with the Department of Agriculture. The d[illegible] of the inspector are to make reports to Mr. Alvord [illegible] facts possible to obtain in connexion with the exp[illegible] dairy products, as to the quality and quantity exporte[illegible] to what points, with the view of putting in force t[illegible] passed by Congress relating to the purity of dairy [illegible] The extent of dairy products exported from New Y[illegible] be gathered from the following facts; for the year [illegible] May 1st, 1901, there were exported 187,285 pac[illegible] butter and 559,554 packages of cheese. The [illegible] laws were amended during the last winter with [illegible] supervise the purity of such exports by the d[illegible] of the Department of Agriculture.

should be administered in full doses to destroy the malarial organisms in the blood and this remedy should be continued for a few weeks after apparent recovery. The breeding places of mosquitoes should be removed by drainage, filling up of holes and surface pools and the emptying of tubs and pails which contain stagnant water. This particular kind of mosquito breeds in surface rainpools or surface stagnant water unless there are fish; equally in pails, tubs, barrels, and tanks of standing water, though they seem to prefer natural accumulations. In pools which cannot be drained it is possible to destroy the mosquito larvæ by the use of petroleum thrown upon the surface, the introduction of minnows and other small fish which eat the larvæ, or by both these methods combined." The Board of Health seek to ascertain the location of cases of malarial fever in order to instruct people as to the danger and the best method of averting it. A case of this disease, whether actively ill or not, if produced by this kind of mosquito, is a constant menace to those in the neighbourhood unless proper precautions are taken to check its spread.

Protest against the Abolition of the Army Canteen.

The last Congress, influenced by the petitions of temperance agitators, abolished the army canteen. The result is reported by military authorities to be a large increase of intemperance, vice, and insubordination. At a recent meeting of the Association of Military Surgeons of the United States the following action was taken:

> The abolition of the army post exchange, or canteen, has resulted, and must inevitably result, in an increase of insubordination, intemperance, discontent, desertion, and disease in the army.

Therefore the association resolved:

> That this body deplores the action of Congress in abolishing the post exchange or canteen, and in the interests of discipline, morality, and sanitation recommends its re establishment at the earliest possible date.

At a subsequent [illegible] of the American Medical Association this resol[illegible] [illegible]mously endorsed.

[illegible] *To In[illegible] [illegible]ulness of Ambulances.*

[illegible] eri[illegible] g[illegible] to Bellevue Dispensary, [illegible]struct and to equip ambulances [illegible] that the treatment of patients [illegible] received into the [illegible] He suggests that [illegible] asbestos or some [illegible] warmer in winter [illegible]ing from shock [illegible]ion of a simple [illegible] with heat-stroke [illegible]gs. Eight thousand of these circulars have been sent out, but only 2000 were answered. From these 277 lepers have been located, and their names and addresses obtained; 100 of these are known to live in New Orleans, and many of them are well to do and of good family. In Minnesota about 20 cases are reported, mostly Scandinavians living in the rural districts; seven cases were reported from New York, three from Chicago, and 15 from San Francisco, 12 of these being confined in the pest-house. In North Dakota there were 15 and but two in South Dakota: in New Mexico there were at least a dozen, and Baltimore reported three; the remainder were scattered throughout the country. As the circulars have brought but few replies comparatively and suspicious districts make no returns the commissioners believe that only about one-fourth of the cases have been reported. It is evident from this investigation that notwithstanding the widespread distribution of leprous patients throughout this country, and their increase in the last decade, there is no cause for alarm, for the disease is not so fatal, or so contagious, or so easily transmitted as tuberculosis. It has also been shown that cures have often been accomplished after two years' treatment. The commission will probably recommend to Congress that national lazarettes should be established in various parts of the country, one perhaps in New Orleans, one in New Mexico, and another in Minnesota or Montana. A generous appropriation will be asked for, sufficient to cover the erection of fine isolated buildings with every appointment for the comfort and pleasure of the sufferers.

Bureau of Food Inspection in the Department of Agriculture.

Mr. B. F. Van Valkenburgh of Brooklyn, for 12 years assistant dairy commissioner and assistant commissioner of agriculture of New York, has just been appointed inspector of dairy exports for this port; the appointment was made under Mr. H. E. Alvord, chief of the dairy division of the Bureau of Animal Industry. An appropriation of $1,500,000 was made by the last Congress for the use of the Secretary of Agriculture as a fund for the establishment of a bureau in connexion with the Department of Agriculture. The duties of the inspector are to make reports to Mr. Alvord of all facts possible to obtain in connexion with the export of dairy products, as to the quality and quantity exported, and to what points, with the view of putting in force the law passed by Congress relating to the purity of dairy exports. The extent of dairy products exported from New York may be gathered from the following facts; for the year ending May 1st, 1901, there were exported 187,285 packages of butter and 559,554 packages of cheese. The agricultural laws were amended during the last winter with a view to supervise the purity of such exports by the dairy division of the Department of Agriculture.

Protection against Malaria.

There has been considerable public excitement aroused lately by the alleged existence of malaria in Central Park, New York City. This large public park, to which great numbers of children resort in the summer, comprises 15 acres of land diversified by elevations and depressions, collections of trees, and small lakes and ponds. Though medical opinion is divided as to the existence of malaria in the park, the Board of Health has taken cognisance of these statements and Dr. Herman M. Biggs, bacteriologist to the department, has prepared a circular of information and advice in regard to precautions to be taken against malarial poisoning. The following is an extract from this circular: "It has been shown by recent investigations that malarial fevers belong to that class of diseases which are transmitted by a certain kind of mosquito, namely, anopheles; this genus is not the common one of this region, but is nevertheless found in some localities. Certain simple precautions will protect a person from infection, living in a malarial district. All mosquitoes having been destroyed, a house should be screened to prevent their return, and the bed also should be protected by a net at night, this being the time that this insect does its work for the most part. A person already infected with malaria should be confined and protected from further contact with the mosquito lest he receive added infection. Quinine should be administered in full doses to destroy the malarial organisms in the blood and this remedy should be continued for a few weeks after apparent recovery. The breeding places of mosquitoes should be removed by drainage, filling up of holes and surface pools and the emptying of tubs and pails which contain stagnant water. This particular kind of mosquito breeds in surface rainpools or surface stagnant water unless there are fish; equally in pails, tubs, barrels, and tanks of standing water, though they seem to prefer natural accumulations. In pools which cannot be drained it is possible to destroy the mosquito larvæ by the use of petroleum thrown upon the surface, the introduction of minnows and other small fish which eat the larvæ, or by both these methods combined." The Board of Health seek to ascertain the location of cases of malarial fever in order to instruct people as to the danger and the best method of averting it. A case of this disease, whether actively ill or not, if produced by this kind of mosquito, is a constant menace to those in the neighbourhood unless proper precautions are taken to check its spread.

Protest against the Abolition of the Army Canteen.

The last Congress, influenced by the petitions of temperance agitators, abolished the army canteen. The result is reported by military authorities to be a large increase of intemperance, vice, and insubordination. At a recent meeting of the Association of Military Surgeons of the United States the following action was taken:

> The abolition of the army post exchange, or canteen, has resulted, and must inevitably result, in an increase of insubordination, intemperance, discontent, desertion, and disease in the army.

Therefore the association resolved:

> That this body deplores the action of Congr[illegible] exchange or canteen, and in the interests of [illegible] sanitation recommends its re-establishment [illegible] date.

At a subsequent meeting of the American Medical Association this resolution was unanimously endorsed.

To Increase the Usefulness of Ambulances.

Dr. Frederick Griffith, surgeon to Bellevue Dispensary, New York, proposes so to construct and to equip ambulances attached to civil hospitals that the treatment of patients may begin at the moment that they are received into the ambulance by the ambulance surgeon. He suggests that the modern ambulance should be lined with asbestos or some non-conductor of heat in order that it may be warmer in winter and cooler in summer. Thus, patients suffering from shock could be kept warm in winter by the addition of a simple heating apparatus and patients affected with heat-stroke could be kept cool by the aid of ice-bags. If the temperature of the ambulance could thus be preserved at a proper degree both summer and winter, there would, in the opinion of this experienced surgeon, be a great saving of life amongst those patients who are suffering from shock in the cooler months and from heat in the hot months of the year and are conveyed to hospitals.

As the circulars have brought but few replies comparatively and suspicious districts make no returns the commissioners believe that only about one-fourth of the cases have been reported. It is evident from this investigation that notwithstanding the widespread distribution of leprous patients throughout this country, and their increase in the last decade, there is no cause for alarm, for the disease is not so fatal, or so contagious, or so easily transmitted as tuberculosis. It has also been shown that cures have often been accomplished after two years' treatment. The commission will probably recommend to Congress that national lazarettes should be established in various parts of the country, one perhaps in New Orleans, one in New Mexico, and another in Minnesota or Montana. A generous appropriation will be asked for, sufficient to cover the erection of fine isolated buildings with every appointment for the comfort and pleasure of the sufferers.

Bureau of Food Inspection in the Department of Agriculture.

Mr. B. F. Van Valkenburgh of Brooklyn, for 12 years assistant dairy commissioner and assistant commissioner of agriculture of New York, has just been appointed inspector of dairy exports for this port; the appointment was made under Mr. H. E. Alvord, chief of the dairy division of the Bureau of Animal Industry. An appropriation of $1,500,000 was made by the last Congress for the use of the Secretary of Agriculture as a fund for the establishment of a bureau in connexion with the Department of Agriculture. The duties of the inspector are to make reports to Mr. Alvord of all facts possible to obtain in connexion with the export of dairy products, as to the quality and quantity exported, and to what points, with the view of putting in force the law passed by Congress relating to the purity of dairy exports. The extent of dairy products exported from New York may be gathered from the following facts; for the year ending May 1st, 1901, there were exported 187,285 packages of butter and 559,554 packages of cheese. The agricultural laws were amended during the last winter with a view to supervise the purity of such exports by the dairy division of the Department of Agriculture.

Protection against Malaria.

There has been considerable public excitement aroused lately by the alleged existence of malaria in Central Park, New York City. This large public park, to which great numbers of children resort in the summer, comprises 15 acres of land diversified by elevations and depressions, collections of trees, and small lakes and ponds. Though medical opinion is divided as to the existence of malaria in the park, the Board of Health has taken cognisance of these statements and Dr. Herman M. Biggs, bacteriologist to the department, has prepared a circular of information and advice in regard to precautions to be taken against malarial poisoning. The following is an extract from this circular: "It has been shown by recent investigations that malarial fevers belong to that class of diseases which are transmitted by a certain kind of mosquito, namely, anopheles; this genus is not the common one of this region, but is nevertheless found in some localities. Certain simple precautions will protect a person from infection, living in a malarial district. All mosquitoes having been destroyed, a house should be screened to prevent their return, and the bed also should be protected by a net at night, this being the time that this insect does its work for the most part. A person already infected with malaria should be confined and protected from further contact with the mosquito lest he receive added infection. Quinine should be administered in full doses to destroy the malarial organisms in the blood and this remedy should be continued for a few weeks after apparent recovery. The breeding places of mosquitoes should be removed by drainage, filling up of holes and surface pools and the emptying of tubs and pails which contain stagnant water. This particular kind of mosquito breeds in surface rainpools or surface stagnant water unless there are fish; equally in pails, tubs, barrels, and tanks of standing water, though they seem to prefer natural accumulations. In pools which cannot be drained it is possible to destroy the mosquito larvæ by the use of petroleum thrown upon the surface, the introduction of minnows and other small fish which eat the larvæ, or by both these methods combined." The Board of Health seek to ascertain the location of cases of malarial fever in order to instruct people as to the danger and the best method of averting it. A case of this disease, whether actively ill or not, if produced by this kind of mosquito, is a constant menace to those in the neighbourhood unless proper precautions are taken to check its spread.

Protest against the Abolition of the Army Canteen.

The last Congress, influenced by the petitions of temperance agitators, abolished the army canteen. The result is reported by military authorities to be a large increase of intemperance, vice, and insubordination. At a recent meeting of the Association of Military Surgeons of the United States the following action was taken:

> The abolition of the army post exchange, or canteen, has resulted, and must inevitably result, in an increase of insubordination, intemperance, discontent, desertion, and disease in the army.

Therefore the association resolved:

> That this body deplores the action of Congress in abolishing the post exchange or canteen, and in the interests of discipline, morality, and sanitation recommends its re-establishment at the earliest possible date.

At a subsequent meeting of the American Medical Association this resolution was unanimously endorsed.

To Increase the Usefulness of Ambulances.

Frederick Griffith, surgeon to Bellevue Dispensary, New York, proposes so to construct and to equip ambulances attached to civil hospitals that the treatment of patients may begin at the moment that they are received into the ambulance by the ambulance surgeon. He suggests that the modern ambulance should be lined with asbestos or some non-conductor of heat in order that it may be warmer in winter and cooler in summer. Thus, patients suffering from shock could be kept warm in winter by the addition of a simple heating apparatus and patients affected with heat-stroke could be kept cool by the aid of ice-bags. If the temperature of the ambulance could thus be preserved at a proper degree both summer and winter, there would, in the opinion of this experienced surgeon, be a great saving of life amongst those patients who are suffering from shock in the cooler months and from heat in the hot months of the year and are conveyed to hospitals.

August 15th.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in Anatomy and Physiology at the July quarterly meeting of the examiners:—

Ernest Francis Rimington Alford and James Armstrong, University College, London; Berkeley Noel Ash, St. Bartholomew's Hospital; Cecil Knight Attlee, B.A. Camb., St. Thomas's Hospital; James Landells Blackie and Frederick John Borrie, Otago University and Middlesex Hospital; John Harold Burridge, King's College, London; Arthur Herbert Bond and Harold Clapham, St. Mary's Hospital; William Bryant and Harold George Shackleford Courtney, St. George's Hospital; Thomas Charles Albert Cleverton, London Hospital; Robert Hugh Cotton, St. Thomas's Hospital; Walter Crampton, University College, Liverpool; Arthur Marcellus De Silva, London Hospital and Ceylon Medical College; William Leonard Dickson, Middlesex Hospital; Kenneth Alan Crawford Doig, Westminster Hospital; William Square Edmond, St. Bartholomew's Hospital; Evan Robert Evans, University College, Liverpool; Harry Loft Evans and Charles Roland Babington Eyre, St. Thomas's Hospital; Harry Arthur Fenton, St. Mary's Hospital; George Ernest Oswald Fenwick, Otago University and University College, London; Harold Nestor Fink, B.A. Camb., and David Hammond Fraser, B.A. Camb., Cambridge University; Walter Taylor Finlayson, St.

Mary's Hospital; William Henry France, Westminster Hospital; Edgar Herbert Good, London Hospital; George Christopher Grundy, Yorkshire College, Leeds; Percy Gully, Charing Cross Hospital; Arthur Lewis Heiser, Daniel Morgan Humby, L.D.S. Eng., Middlesex Hospital; George Wykeham Heron, Westminster Hospital; Thomas Martin Hughes, Owens College, Manchester; [illegible]

[illegible] and James [illegible], London Hospital; John Edward Litton and [illegible] St. Bartholomew's Hospital; Cecil [illegible] Walton, Thomas Jo[illegible] Charles Woollatt, L[illegible] Birmingham University; [illegible] Manchester; Arthur Den[illegible] St. Bartholomew's Hos[illegible] Cantab., St Andrew's U[illegible] University College, London.

Passed in Physiology only: Alexander Vigers Benson, London Hospital.

52 gentlemen were referred in both subjects, and one in anatomy only.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Preliminary Science Examination for the Licence in Dental Surgery at the July quarterly meeting of the examiners:—

Walter Breese, Birkbeck Institute, John Piercy Brown, Holt School of Science, Birkenhead; Herbert Edgar Collett and William Ewart Derriman, Guy's Hospital; James Thomas Daly, Middlesex Hospital; Norman Sydney Deravin, Melbourne University [illegible] Birmingham University; Samuel [illegible], Owens College, Manchester; Matthew Jackson, Middlesex Hospital; Herbert Henning James, Charing Cross Hospital; John Jackson Law, Technical School, Blackburn, George Edward McMahon, Holt School of Science, Birkenhead, Arthur Miller, Harris Institute, Preston; Arthur Lovering Moon, Guy's Hospital; Frederick Rudolph Moser, Charing Cross Hospital, Norman McLeod Nibbs and John Arnold Oates, Birkbeck Institute; Arthur Brearley Oddie, William Charles Retallack and John Stuart Sawer, Birmingham University; Sydney William Robinson and Robert Alexander Scott, Guy's Hospital, Walter Duckett Southern, Municipal Technical College, Derby, Bernard Maxwell Stephens, Middlesex Hospital; Francis Edgar Sprawson and Francis Raymond Wilson, Birkbeck Institute, and Henry Harrison Tomlinson, Holt School of Science, Birkenhead.

UNIVERSITY OF LONDON.—At the Preliminary Scientific Examination held in July the following candidates were successful:—

ENTIRE EXAMINATION.

First Division.—Frank Cyril Harvie Bennett, St. Mary's Hospital; James Francis Blackett, Merchant Venturers' Technical College, [illegible] John Smeed Bookless, Guy's [illegible] Olave's Grammar School; [illegible] Hospital; Cuthbert Garrard [illegible] University Tutorial College; [illegible] Leonard Colebrook, London [illegible] School of Medicine for [illegible] School of Medicine and [illegible] Edwin Dobbin, University [illegible] Westminster Hospital [illegible] Roker Evans, University College, Paul Leon Giuseppi, St. Bartholomew's Hospital; John Norman Glaister, University College, Bertram Thomas Johnson Glover, University College, Liverpool; Thomas Mellor Hardy, [illegible] University College, Liverpool.

Second Division.—[illegible] Hospital.

CHEMISTRY AND EXPERIMENTAL PHYSICS.

Arnold Alcock, Owens College; Leonard Tilsley Baker, Dulwich [illegible] Elisabeth Mary Gibbon,* Alwyne Institute; Carleton Wyndham [illegible] College; Edith Mary Guest,* Oxford [illegible] Hall, Alwyne Institute; [illegible] College; Herbert Vawser [illegible] and private tuition; Arthur [illegible] Bristol, and University Tutorial [illegible] Jack, Dulwich College; Harold Emlyn Jones, London Hospital, Edward Cronin Lowe,* Guy's [illegible] Tutorial College; Evan David [illegible]; Cecil Frederick Robertson, [illegible] Sanderson, St. Thomas's [illegible]* Oxford University; Claro [illegible] College, Liverpool, and private [illegible], Guy's Hospital; [illegible] Bartholomew's Hospital; William [illegible], Sidney Bernard Watson, London Hospital; Charles McMoran Wilson,* Owens College, and Arthur Zorab, Guy's Hospital.

BIOLOGY.

Godfrey Frederick Ely Allison, Owens College; Charles Ernest Anderson, King's College, James Applevard, University College; Charles Anthony Basker, Guy's Hospital; Lionel Hethorn Booth,* Epsom and University Tutorial Colleges; John Albert Bullbrook, Guy's Hospital, Angel Camacho, Charing-cross Hospital; Howard James Burrell Cane, University Tutorial College and private study; Robert Colgate, University College; Bella Dawson, Westfield College, Allan Baines Fearnley, private study and University Tutorial College, Archibald Thomas William Forrester, St.

leaves, and some of the worst diseases of plants occur in cases in which a fungus is growing on the roots.

Now I would go back for a moment, for I have not mentioned my best instance of competitive nutrition, and it is a curious one. I have a very remarkable instance of that on my own farm. I have said that the roots are not merely for fixing the tree to the ground but also for taking up nutriment; and in order to best devote themselves to fulfilling their double vocation, whilst some of the roots go down deeply and spread out as fixation structures, others do not go down at all, but come up to the top purposely, with the view of getting the first supply of rain and other nutriment that there may be about, such as manure which may exist in the upper layers of the soil. The poplar and some other trees send out numerous rootlets to gather up the moisture and nutriment for the parent tree. In one particular poplar which I have under observation numberless roots have in this way been sent out and reaching the surface 30 or 40 feet from the parent tree have there budded and grown up on their own account. Thus we have now a crescentic line of small poplar trees, the parent forming the centre of the arc. What will be the effect on the parent of these little trees growing up around it? The effect seems practically certain that it will be killed. These branches which were sent out for food for the parent tree have set up on their own account, and as a result of that the parent will have to die. That may be taken as an instance of the diversion of nutrition from one part of an organism to another, if you consider these separate poplars as part of one whole organism. Here is an instance in which a mother tree has sent out her colonies, and these colonies having taken up what was desired by the mother for herself they have not returned it to her, but have kept it themselves, and the result will be the death of the mother tree.

I have already briefly stated that the roots of trees are often attacked by fungi. These also often attack the stems of trees; and here some of the most interesting lessons may be learnt in reference to the pathology of animals. Sometimes fungi will attack quite healthy trees, sometimes they will attack diseased trees, and very often they will attack wounded trees, just as you know occurs in diseases in the human subject. We have certain specific animal poisons, those of the fevers, which may attack perfectly healthy persons, and good health seems to be no security whatever against them. Small-pox is the best instance of that. Indeed, it is even thought that those who are most healthy and have the best supply of fluids and the richest blood in their bodies suffer more severely than others because they have a larger field for the development of the parasitic poison which has been introduced. It is so also in the matter of fungi on plants. There are, of course, an immense variety of these fungi, which have very different tendencies. Some may grow on perfectly healthy plants, no predisposing influence being necessary to their growth; while others wait until the plant or tree has been injured, or until it is sickly, or until it is nearly dead, before they will or can attack it.

Now, the extreme importance of wounds, and the great importance of what we may call the antiseptic treatment of wounds in plants, is illustrated quite as definitely in vegetable as in animal pathology. A wound to the bark of a plant will allow the fungus to settle on it and grow in it and cause disease of the stem, and it will convert the wood tissue of that stem into a soft structure, destroying the wood, or "delignifying" it, as it is called, and it will also destroy the channels for the passage of fluids whose *absorption* is *necessary* for the life of the plant. In other words, the fungus will make the plant rot. I have here a piece of wood in which there are certain blue lines, and if you look at a cross section of the structure you will see that there is a circl f blue lines which correspond with those shown in cut. Each of these blue lines represents the g us which you may demonstrate with the micro- growths may affect the whole length of a tree. he stem of the tree may be very extensively disorg the timber will be converted into a structure ger capable of carrying on the passage of the sa all uncommon. Those of you who have acces ons of Weymouth pines will often find one of t trees with a single bough completely brown and d st of the tree being apparently quite healthy. Yo , too, that some of these boughs are at a consider where they are not very likely to have been injur matter of fact no twigs have been broken off, but very likely you will be able to find that there is a scar, such as I show in this one where a little injury has occurred. That injury may have been due to the attack of a bird or a hailstone, or from a blow, and that slight injury will have allowed the fungus to enter; and that fungus, having passed into the wound, will pass into the stem of the tree, and will probably grow and work up its long axis. Possibly it may not grow very far, as these things differ in growth tendencies. But in those instances in which a whole branch becomes dead it will be found that the fungus has entered at one single wound and has passed into the branch, and that branch has had its circulation interfered with so that the leaves have died, the remaining part of the tree being still healthy. Next the fungus may tend to flower and produce on the stem a spore-bearing body which is equivalent to its flower. This is a very destructive fungus indeed; it spreads far and wide in the tissues and produces the death of the wood. During the last year we have noticed a curious fact at Haslemere. On the Weymouth pine there is a very common fungus called *Peridermium Strobi*, and that fungus has been known on the continent to be liable to be attacked by another fungus. It has happened to us to identify this parasite on a parasite, and it appears to have been the first time that it has been noticed in England. It is very difficult to say where the germs have come from, but we have found a number of cases on the Weymouth pine at Haslemere, and we have been told at Kew that it had not been observed, to the knowledge of the authorities there, in England before, though, as I have said, it has long been well recognised on the continent. The name of the second fungus, if you wish for it, is *Tubercularia maxima*. It may be assumed that there is some law which associates the two kinds of fungus together. So I now hint that the protection of a wound from infectoin is just as necessary in the case of a plant as it is in an animal, though it is not a practicable measure in the great majority of cases. When we cut the bough off a tree it is not often practicable to use antiseptics, but when dealing with valuable trees we should smear the wound which is left by cutting off the bough, to prevent the entrance of a fungus into it, because any injury to the bark involves the risk that a fungus will so enter. A fungus is apt to destroy fir-trees on a large scale by inducing decay of the middle of the wood; it creeps up the whole stem of the tree, and then the tree will be observed to be sickly and it will die. The middle of that tree will afterwards be found to be rotten. We find it to be due to a fungous growth. All rot and decomposition are due to the growth of fungi; it is not chemical decomposition. The tree is quite hollow inside. The source of infection in that case—and here we have another interesting thing to think about in reference to infection in animals—is believed to be by the roots and through the agency of rabbits and rats. The rabbit burrows under the fir-tree, eats the root and injures it a little, and then it runs about under other trees and gathers various things on its back, spores of fungi and so on, and then runs back into its burrow and carries the fungus with it and infects the root, and the fungus grows the whole length of the tree and disorganises it.

Another point of great interest in reference to fungus-life in trees and plants is the fact that many forms of fungi appear to be capable of almost indefinite periods of latency. They do not always grow—the fungus may be a long time without growing; and here we have another important lesson corroborating what we hinted at in a former lecture when speaking of tuberculosis, that the tubercle bacillus can remain for very long periods of time in the tissues of the body without producing any morbid condition whatever. Sometimes it may live for his whole life in the tissues of its host and not cause any discomfort. There are hundreds of instances in vegetable pathology in illustration of that. The fungus may be present but there may be no active disease; whereas in another case there may be no visible fungus present, but there may be a considerable amount of disease.

There are some curious facts with regard to idiosyncrasy in trees and vegetables. In animal pathology we have to make a great allowance—and I do not think we can make too much allowance—for original differences, of which we can detect no evidence until the disease attacks the individual, and then we find no two individuals are exactly alike as regards the disease. The same disease or the same poison may attack one person and produce a very different result and intensity of disease in him than in another. Yet we do not see any great difference in the persons until the disease occurs To such we apply the term "idiosyncrasy," and we recognise under that term the fact that different individuals are endowed in different ways and react in different ways to the influence of poisons That is a condition which is primary but which is not revealed until there is disease. This idiosyncrasy is a personal peculiarity, and personal peculiarity [illegible] nal world I have [illegible] the same field, of [illegible] I can tell, under [illegible] tree has kept its leaves on all the winter, while the other has shed them in the ordinary way The one which kept the leaves on from last year had its leaves turn brown This does not appertain to one bough of the tree, there is the same peculiarity in the whole of the tree—it has got a personal character and that personal character is a tendency to keep on its autumn leaves Everyone who has been in the country will have seen instances of that retention of the summer foliage, which should have fallen in the autumn, through the winter Young beech trees which grow in hedges and have been cut down are very apt to do this and you can notice examples of it in many trees In the case of the beech trees one tree may be close to another and in exactly the same conditions, one keeping its leaves and the other dropping them This is an instance of a peculiar tendency or idiosyncrasy occurring in the trees, of which we can give no explanation There is an evergreen oak, and my suggestion as regards this phenomenon is that it is an attempt on the part of the oak to become an evergreen It is one of those numerous experiments which life processes are constantly making One of these oaks is trying the experiment as to whether it can keep its leaves through the winter It succeeds in keeping them but they turn brown In process of time it may succeed in keeping them green throughout the winter

Another little lesson which I think we can get from the observation of fungi is the law of diffusion But you must understand that the study of fungi which attack plants and *trees is an immense subject* I expect you are taught in the medical and surgical theatres that the disease known as "tetanus" is due to a specific form of microbe and that it is conveyed by inoculation The disease is always introduced as an inoculation Now, there are certain facts which make that statement difficult of substantiation I am not now going to dispute it, but only to hint at things which make it improbable and to suggest that it is a matter upon which we may possibly get some light by the examination of what occurs in vegetable life Is it not very curious that the germ which produces tetanus should be so widely diffused and yet should so seldom produce its effects? We get no real epidemics of tetanus If it is a specific germ why do we not get a whole lot of tetanus cases a whole lot of tetanus poison lurking in the soil? Instead of that we get one tetanus case here and another there but nothing at all like an epidemic, the cases are almost equally scattered about and there is no local prevalence. We know it is very prevalent in tropical countries, but in England we get nothing which will justify us in regarding it as an epidemic because it is never unusually prevalent at any one time or locality *Now* it is very curious that a specific germ having that power should be so widely diffused However, we have some similar facts in reference to vegetable The fungus which attacks the [illegible] d I think it attacks [illegible] will be that fungus [illegible] attack it That is an illustration of the law of diffusion and there are many questions *relative to the* laws of diffusion with regard to fungi which I suggest are well worthy of our study Science has, in some branches, enlightened us to where these germs are to be sought for and has enabled us to destroy them We may hope for further discoveries

And here I have to allude to another branch of the subject which is of great interest, and to extend a little caution in the inferences which we draw based upon an incomplete examination of the facts in reference to the different species of fungi which attack the human skin There are a number of these fungi One of them produces pityriasis versicolor another causes true favus, another causes ringworm and it is suggested that [illegible] ringworm I would hint th[illegible] n believing that these di[illegible] lief is that from the fungus of common ringworm of the scalp you can produce tinea versicolor, the common chloasma of the chest of [illegible] not ringworm but tinea versicolor on the chest I therefore suggest that we should be a little cautious in inferring because the external appearances produced by the disease which we know as tinea versicolor *are different from those which we* know as ringworm and are diagnosable easily from each other, that the two things are not transmutable After all it may be a modification of the fungous growth and it may be the same fungus which produces the two My belief is that it is, and that the large fungus ringworm and the small fungus ringworm are very likely the same, and that the fungus which produces favus, which is very much less common is only a very modified form of that which produces ordinary ringworm A great lesson in caution on this point is to be derived also from the old doctrine as regards rust on wheat You know that rust on wheat is a disease in which the leaf of the wheat becomes brown all over and dies prematurely The wheat crop is very much injured by this destruction of its leafage It may occur on grass and on wheat. But as to wheat especially on account of the importance of the crop it became an urgent question with agriculturists as to how it could be prevented Farmers observed that where the common barberry grew in the hedges there was likely to be rust in the wheat. Botanists were asked about this and they at once declared that it was impossible, *they said* that they recognised the fungus which grew on the barberry, and that they also recognised that which was produced on the wheat and they said that it was impossible that they could be the same as they belonged to totally different species The farmers protested that where the barberry grew there was the rust and notwithstanding the opinion of the botanists they felt that there was some connexion and they acted upon their belief by getting rid of the barberry trees to prevent the rust in their wheat A law was passed in the State of Massachusetts calling upon farmers to exterminate all barberry trees out of their hedges, it was made compulsory on farmers to do this If they did not do it the work was to be carried out by the local parish authority and the farmers were to be charged with it All this time the scientific men were saying that the farmers were ignoramuses who did not study botany and did not understand the matter because the fungi on the two things were totally distinct And then came the great discovery which is now illustrated in many departments of fungology that the plant is one which requires two different hosts in one host it produces one special spore and in another another spore It is the same fungus which develops on the barberry and then being blown off there takes root on the wheat and becomes spread over the wheat fields Thus the farmers were shown to be quite right—that it was a transmutation and change of form of the same kind of fungus due to the different environment which was thus seen in different stages of its development That I mention as an instance in which science has lagged behind the observation of practical men As scientific men it is for us to be modest in our statements and not to urge too strongly theories which seem contradicted by the general verdict of experience We should learn wherever we can listen to *everybody, and take into account the propositions, and* maybe the mistakes of those who have had opportunities of making practical observations so that we may arrive at the truth from them though it may not at first appear to be the scientific truth So I think with regard to the study of many forms of disease that we shall with further observation simplify our conceptions *with regard to vegetables and animals* and that we shall find that many of the diseases which we have considered as separate are not in reality so, or not so much so as we have thought.

Now I come to a different subject—namely, the effect of living parasites in inducing disease on plants I must hasten through these very curious specimens which I have placed before you They illustrate various doctrines and it is with the doctrines I am dealing to-day—those which have a wide bearing On the table you will see many good specimens of what go by the name of pine apple cones —a very appropriate name because they look like pine apples These are not seed cones The tree is the Norwegian spruce The cones are caused by the presence of an insect, the aphis one of *the innumerable aphides The aphides* are ubiquitous and they affect almost every plant Some aphides affect many plants there are an enormous number with very slight differences, but each for the most part attacks its own particular plant. The history is that a mother aphis in the spring comes forth, having been lodged somewhere on the tree, perhaps in the bark, and crawls up the stem of the fir-tree, and deposits a number of eggs just at the point where one of the branches is about to develop. She surrounds herself and her eggs with what looks like cotton-wool. If you look in the spring you will be able to identify what looks like a little mass of white wool deposit. In this cotton-wool deposit the little eggs are glued together, a beautiful object, the eggs being hung together like a bunch of grapes and kept warm in the woolly covering at the foot of the little growing stem. What is the effect of the presence of these eggs? The mother aphis does not burrow at all, but she wounds the bark a little in order to glue the eggs into the place and make them adhere. The result of this is that the bark at once begins to thicken, and the little leaves which should be ordinarily needle-shaped thicken at their bases and form bracts arranged like a cone. The eggs are hatched out where they were placed at the foot of the twig, and the larvæ thus hatched from the eggs crawl up this cone; the cone is still open at these bracts and the aphides crawl in. Then the bracts close down and shut the aphides in, and there they rest for six weeks and grow. Each fixes its proboscis into the newly-formed tissue, sucks its nutriment, and there stays until it attains its full growth. Then the cone opens just as a seed-cone opens, and the aphis creeps out just as the seed drops out of a seed-cone. The little insect has rudimentary wings, and there is not only one of them but thousands, and they next fix themselves to the nearest leaf, and having fixed their feet they split their coats open and the fly comes out and leaves its limbs and rudimentary wings glued to the leaf. There are two of these growths under the microscope, and very curious they are. No one would know what they are unless they were acquainted with how they had resulted. The fly comes out with different wings and flies away, and being destined for a short duration of life is ready to propagate its kind. This is one of the very best instances I could give you of what is called "a gall." Let us use no mistaken phraseology; let us not speak of these as being made by the insect—they are not made by the insect. It is the result of the influence brought to bear upon the plant by the insect, and what we have to observe is a lesion of altered nutrition, on the part of the plant, due to local irritation. If I made use of a bold expression I might say that the plant mistakes the irritation produced by the living egg for the irritation produced by its own living seed. If there were living seeds the plant would grow a cone about them. It is obvious that the local irritation cannot be consciously appreciated by the plant, and that the tendency to growth on the part of its tissues is the same thing with different kinds of irritation The gall is a product of the tree caused by the insect, but it is not a thing which is made by the insect in any sense whatever The tree builds it and the kind of gall which results depends on the life and nutrition tendencies of the tree. I might exemplify that by saying that here we have the character of the tree illustrated. There are several other species of fir-trees very similar to these common Norwegian spruce. In another, in which the tree is very nearly allied indeed to this—so nearly allied to it that I do not know them apart and have no means of distinction—the tendency is to produce the cone at the very tip of the twig, and to produce a very small one But there are other fir-trees very like this which never produce these false cones. It is only this one kind which has that tendency. One could go through the various kinds of fir-trees and show that an easy means of distinguishing between them is by the different diseases which they develop. If a fir-tree I was looking at had developed the false cones I should be almost sure that it was a Norwegian spruce. For instance, the distinction between the Douglas spruce and the Norwegian spruce is not always easy, but by this gall I know directly that this is a Norwegian spruce. The aphis probably tries experiments on the Douglas spruce, but the tree will not grow its cones. The tree determines the kind of gall which will be produced. Another general law in galls is that the character will depend a good deal on the precise part of the tree which is attacked. There are an immense variety of galls, and the variety depends partly on the difference of the trees and in part on the spot at which the insect makes its attack. Oak-trees are an illustration of this. Here is one of the commonest galls, which is sometimes called a "marble gall." But there are endless varieties of galls. Some are produced on the middle of the leaves and others are produced on the main midrib; and according to the precise tim in the life of the plant and the part attacked so will be th growth which results from the irritation of the gall insec whether fly or aphis. The precise species of insect is, o course, important, but it is far from determining the whol phenomena.

Such, then, are the general laws. I have here a whole lot of specimens, but I do not know that they will add very much to the subject; you may take them and examine them for yourselves afterwards. But a country walk will furnish you with plenty of opportunities for observation, and that is always preferable to taking the observations of others. In this case of the oak-gall the insect carefully selects the actively growing tree, where the sap is moving, deposits its egg in a certain place, and then the tendency for this growth occurs. The green gall is formed and then that gall becomes woody, and the wood serves as a protection for the insect in the winter. Some of these cynips come out in the autumn. I cut this one open and find that it has not been hatched; there it is in the middle of the gall, almost ready to come out. If we had waited a little longer it would have come out as a fly. I have sometimes cut these when the fly was just ready to come forth and it has come out with apparent gratitude for its easy release.

A CASE OF CEREBRAL ABSCESS COMPLICATING GUNSHOT INJURY WITH BILATERAL LOSS OF PERIPHERAL VISION.

By ALFRED W. SANDERS, M.D. LOND., F.R.C.S. ENG.,
LATE DEMONSTRATOR OF ANATOMY, ST. MARY'S HOSPITAL; SURGEON TO VOLKS' HOSPITAL, PRETORIA; LATE CIVIL SURGEON IN SOUTH AFRICA.

THE following case came under my care while working in No. 2 General Hospital at Pretoria.

On the night of Dec. 26th, 1900, the patient, a private in the 1st Liverpool Regiment, while fighting in the trenches a Helvetia was struck on the back of the head by a rifle bullet. From the history that he gave I gathered that the loss of sight had been immediate, but whether the blindness was total I could not ascertain. Ten days later he was admitted into the hospital, having come down by train. He was said to have lost consciousness while travelling and from one of his comrades I learnt that he had certainly got worse during the journey. When first I saw him he was lying in bed with limbs extended, breathing deeply and with eyes closed; he could be roused, however, and then became somewhat noisy and abusive. The temperature was 103·5°F. and the pulse was 76, with a sharp sudden beat and somewhat increased tension. In the right occipital region was a suppurating wound about two inches long. There was no evident paralysis. The pupils were equal and reacted to light. It was decided to explore the wound at once and chloroform was administered, very little being required.

The scalp wound having been enlarged a somewhat dum bell-shaped aperture was found in the skull. The shape o the aperture conveyed the impression that the bullet ha just entered and emerged from the cranial cavity, splinterin all the bone in its path. The margin was splintered and several small fragments lay loose in the wound. Bulging into this hole was a portion of brain which did not pulsate but felt tense and elastic. It was decided to puncture this with a trocar and cannula. While removing a fragment of bone, however, a bead of pus was seen to escape and a probe inserted at this point passed nearly two inches into the brain. The opening was dilated and fully four drachms of pus and broken-down brain matter came away. No fragments of bone were felt in the cavity which was then gently washed out with sterilised water and drained by a fair-sized tube. The aperture in the skull had its centre about two and a half inches above the external occipital protuberance and one and a half inches to the right of the median line. The next day, though still drowsy and irritable, the patient was more sensible. The morning temperature was 100°, and the evening was 102°. The pulse was 54. On Jan. 8th he was much more sensible and complained of loss of sight. The temperature was 100°. On the 10th his temperature was normal, the wound looked healthy, and the amount of discharge had diminished. He still complained of loss of sight, *but was able to* distinguish the sister and the colour of her dress. He improved uninterruptedly as regards the local condition and though childish for a few days in the end appeared mentally quite normal On the 14th, on making a *rough examination, I found there was* marked diminution of the visual fields. Four weeks later, the wound having healed, he was able to get up His gait was uncertain and as he walked he seemed to peer in front of him. *With a roughly-made perimeter I mapped out the* visual fields as accurately as possible and found that in either eye vision was limited to quite a small area around the fixation point. In most directions this did not exceed five degrees and in none did it reach 10 degrees Figs 1 and 2 indicate the kind of chart obtained I could make out no marked difference in the eyes. He was unable to read half-inch *type further away than two feet At the* end of February, when I left Pretoria, no improvement in vision had been made He had never been able to read, but could spell out the letters on a card. There was no evidence of "mind blindness"

FIG 1

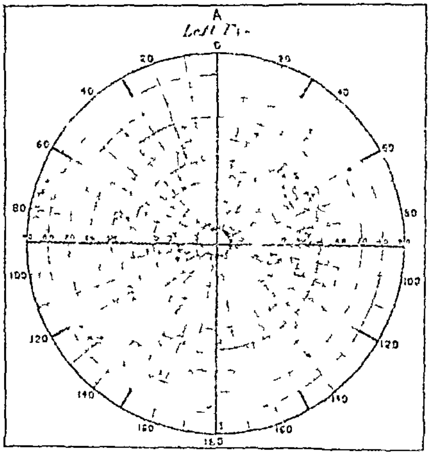

FIG 2.

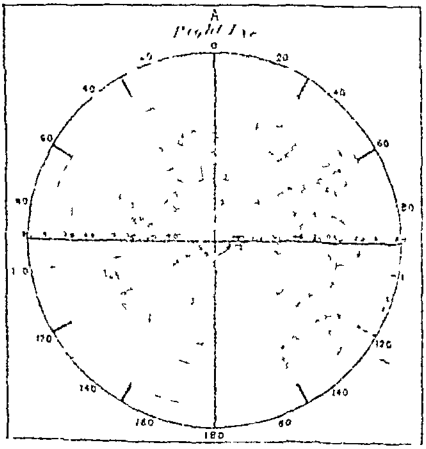
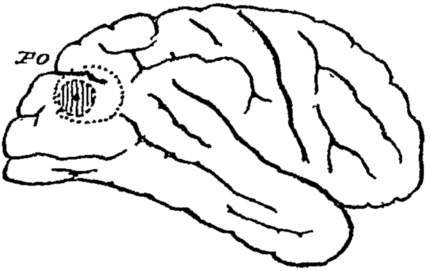


Figs 1 and 2 show somewhat diagrammatically the kind of perimetric tracing obtained The visual area *is seen to be* very small, extending little beyond the macular region in any direction

I have ventured *to record this case on account* of the rarity with which such lesions occur and because of the extensive impairment of vision produced by an apparently unilateral injury

As regards the site of the lesion the aperture in the bone was dumb bell shaped with the long axis horizontal, the centre being one and a half inches from the median line and two and a half inches above the external occipital protuberance The drainage tube entered perpendicularly to the surface of the skull for fully one and a half inches. There must, therefore, have been considerable damage to the cortex and underlying white matter. From the position of the skull wound and its character I see no reason whatever to suppose that there was any injury to the left side of the brain In order to ascertain the portion of brain most probably involved in the injury, I marked out on a skull the site of the perforation and fixing the pin of a trephine two and a half inches above the external occipital protuberance and one and a half inches from the middle line of the head removed a one-inch disc of bone The bone removed was part of the parietal bone immediately adjacent to its posterior border The cortex exposed was the fore part of the occipital lobe A probe passed one and a half inches into the brain substance vertically to the surface penetrated the white matter of the occipital lobe, entered that underlying the posterior part of the parietal lobe (angular gyrus), and nearly penetrated the lateral ventricle. The portions of the brain actually destroyed by the injury and abscess were, I believe, (1) the anterior part of the occipital cortex on its outer aspect, (2) the hindmost portion of the angular gyrus, and (3) part of the white substance of the occipital lobe, including part of the "optic radiation," and the white matter underlying somewhat deeply the angular gyrus (Fig 3).

FIG 3



Drawing of a brain showing area of cortex exposed in trephine wound and possible extent of sub-cortical injury in the case recorded P O, Parieto-occipital fissure

The point of chief interest and greatest difficulty is to explain the very extensive *impairment of both visual fields* produced by an apparently unilateral lesion The question naturally arises Was the injury strictly confined to the one side? At the time of operation nothing was seen which in any way indicated that *the injury had extended to the left* side The fracture was clearly local and situated well to the right of the middle line, and though the margins were splintered there were no fissures extending beyond. The abscess was not large and *after the* matter had been evacuated pulsation was visible in the escaping fluid Very little discharge came from the tube subsequently and the wound healed quickly and without any trouble whatever. The shape of the aperture in the skull seemed to indicate clearly that the bullet had just entered and emerged and no fragments of metal were found The left occipital lobe would be protected from pressure or invasion by the abscess *by the strongest portion of the falx cerebri*

What exactly is the "visual area" of the cortex is still open to discussion. The portions of the cortex to which this function is generally assigned are that of the occipital lobe—*especially its mesial aspect—and the angular gyrus It is* with regard to the latter that there is most uncertainty. Schäfer[1] says: "With regard to the angular gyrus the experiments with Sanger Brown were entirely contradictory to those of Ferrier and Yeo. In animals in which the grey matter of this convolution was destroyed on one or both sides we could discover no defect of vision." He instances, too, the observations of Flechsig on the course of the fibres of the optic radiation. Tracing these during the process of myelination that observer found that none went to the angular gyrus and he therefore excludes this portion of the cortex from the "visual area." Other observers, reasoning chiefly on clinical evidence, take an opposite view. Sir W. R. Gowers[2] says: "The two half vision centres are probably blended in a higher visual centre in front of the occipital lobe. The arrangement is, however, complex. In each centre both fields are represented, but chiefly that of the opposite eye."

This region is also regarded as the mind vision-centre, and a lesion here is believed to cause therefore crossed amblyopia with some impairment of vision on the same side and mind-blindness. "In the very few post-mortem examinations in cases with crossed amblyopia the posterior and inferior part of the parietal lobe—i.e., the angular gyrus in its widest sense—has been involved in the disease." As the higher centre is supposed to be connected to the retinæ it is supposed that a lesion on one side may be to some extent compensated by the opposite hemisphere.

The part of the visual cortex which represents the macular region is generally believed to be that lying on either side of the fore part of the calcarine fissure. Schäfer found that in the monkey "bilateral injury of both mesial surfaces of the occipital lobes appeared to cause loss of central vision, peripheral vision being intact." The cortical representation of the macula, however, appears to be not truly hemianopic but to represent more than the corresponding half of each retina, for generally in cases of hemianopia due to cortical lesion the line of demarcation skirts or goes through the macular region and not through the fixation point.

The case under discussion tends, I think, to show that in man both sides of both retinæ are represented to some extent on one side of the brain. The lesion in the occipital lobe would account for the loss of vision in the left side of the visual fields, and to those who regard the angular gyrus as representing both retinæ, especially the opposite one, the destruction produced by the abscess beneath the angular gyrus would account for the loss of vision in the remainder of the fields. That both macular regions should have escaped, partially at any rate, is possibly to be explained by the bilateral representation of portions of both maculæ. It is difficult, however, to see why the loss of vision in the right side of the visual fields should have been so great. Possibly a gradual recovery will take place in this respect. On the whole, then, I think that the case tends to support the opinion of those who regard the angular gyrus as part of the "visual cortex" and may be described as one of left hemianopia due to the damage to the occipital lobe, with concentric contraction of the fields of vision on the same side as the lesion, due to destruction of fibres of the optic radiation beneath the angular gyrus and to the injury to that convolution. It is, however, of interest to note that there was no evidence of mind-blindness. The patient was unable to read, but he could spell out printed letters and never failed to recognise objects.

For assistance and guidance in the treatment and for permission to publish an account of this case I have to thank Lieutenant-Colonel G. H. Sylvester, R.A.M.C., the officer in charge of No. 2 General Hospital.

LYNTON COTTAGE HOSPITAL.—The working men of Lynton and Lynmouth, Devon, for the past two years have held an industrial fair in aid of the funds of the Lynton Cottage Hospital. The fair which was held last week resulted in a sum of £90 being handed over to the institution; in 1900 £65 were obtained.

VACCINATION RETURNS.—At the meeting of the Uxbridge Board of Guardians held on August 20th it was reported that during the six months ended Dec. 31st, 1900, there were 457 births in the several parishes of the union; of these children 179 were successfully vaccinated and 108 were exempted.

SOME RECENT INQUIRIES AND RESEARCHES INTO THE POISONOUS PROPERTIES OF NAPHTHALENE AND THE AROMATIC COMPOUNDS.

BY R. P. WHITE, M.D. EDIN., M.R.C.S. ENG.,
HONORARY MEDICAL OFFICER, ROYAL ALBERT EDWARD INFIRMARY, WIGAN;

AND

JOHN HAY, M.D. VICT., M.R.C.S. ENG., &c.,
MEDICAL TUTOR AND REGISTRAR, ROYAL INFIRMARY, LIVERPOOL; ASSISTANT PHYSICIAN, STANLEY HOSPITAL, LIVERPOOL.

THE manufacture and employment of naphthalene and of the aromatic series of compounds constitutes a comparatively large industry both in this and other countries, and especially is this the case since they form necessary and essential ingredients in what are now known as the "high explosives." In the short time at my disposal it will be quite impossible for me (R. P. W.) to give a detailed account of the symptomatology, pathology, and precautions to be used when handling these substances. These points were considered by me in 1892,[1] also more recently in an article which will shortly appear in Dr. T. Oliver's book upon "Industrial Occupations." This paper deals solely with their dosage and their relative poisonous actions, and then some recent investigations upon the absorbability of the dinitro-benzene compounds through the skin. This last point is the more important as Strusmann and Strecker[2] in a recent paper upon the subject of dinitro-benzene rather seem to infer that there is no absorption by the skin.

In large doses the nitrated aromatic compounds act powerfully upon the higher centres, producing coma and death. In smaller doses their effects are noticed upon the sympathetic and peripheral nerves, inducing loss of vaso-motor tone and the symptoms of multiple neuritis. Their action upon the blood is in most cases definite and characteristic; many of them seem to form chemical compounds with the hæmoglobin, producing cyanosis, deficient oxidation, and breaking up of the blood cells. With some of these poisons hæmolysis occurs and much degeneration takes place in the tissues of certain organs. The following conclusions we have drawn partly from my own experience with workmen employed in the manufacture of high explosives, partly from experiments upon animals, and partly from the experience of others. The naphthalene group, which is largely used, is probably much less dangerous than are the benzene and toluene groups. Of the naphthalene compounds it is probable that the dinitro-benzene naphthalene is more poisonous than the mono-nitro preparation.

Coming to the benzene group, mono-nitro-benzene when given by the mouth to cats does not seem to affect them at all; they rather seem to thrive and grow fat upon it. The dinitro-benzene is, on the other hand, exceedingly poisonous both to animals and men. The smallest lethal dose of dinitro-benzene for a cat of six pounds is 0·08 gramme if given by the mouth in one dose. In one instance a dose of 0·06 gramme of dinitro-benzene was not fatal but almost so. 1·2 grammes given to a cat by the mouth was fatal in about three hours. In the same ratio the lethal dose for a man of 10 stones would equal 1·82 grammes, but in all probability a smaller dose would be fatal. A lethal dose when divided up and given over a consecutive number of days does not kill—for instance, in a case where we gave 0·09 gramme of dinitro-benzene to a cat in doses of 0·04, 0·02, 0·01, and 0·02 gramme over a period of four days without causing death. It has been stated that dinitro-benzene when taken into the stomach shows a latent period before exhibiting its action. In our experience of experiments upon animals we find that if an animal survives a given dose of the poison for 24 hours it will recover entirely. This in all probability applies also to man. The vapour when inhaled acts immediately and the other preparations are readily absorbed if in a suitable solution. Hypodermically a dose of 0·04 gramme of dinitro-benzene was not fatal to a cat. From experiments with trinitro benzene we found that it was distinctly not very much more poisonous than dinitro-benzene Mononitro toluene is quite inert when administered to cats Our personal experience of nitrotoluene is small, but on inquiries from the places where it is manufactured we were told that it was much too dangerous to work with—in fact, it was described as "simply hellish" The trinitro compound of toluene appears less poisonous that its dinitro benzene equivalent For comparison 50 minims of a 1 per cent. solution of trinitro benzene were hypodermically injected into a cat, causing death in a few hours In another cat an injection of 60 minims of a 1 per cent solution of trinitrotoluene produced only slight symptoms of cyanosis The comparative harmlessness of trinitrotoluene is a very important fact, especially if, as we believe it does, it applies to man Trinitrotoluene has been occasionally substituted for dinitro-benzene in some manufactories with great benefit to the workmen If it can be found practically possible to replace the benzene compound by the toluene compound in all these industries it will be a very valuable step

[2] Friedreich's Blätter für gerichtliche Medicin, July and August, 1901.

So much, then for the comparative poisonous properties of naphthalene and the aromatic series of nitro compounds These all refer to their action when introduced into the system either hypodermically or by the mouth I (R. P W) have long felt that dinitro benzene, with which I am specially familiar, is very largely absorbed by the skin, but up till quite recently I could find no conclusive evidence that this substance was capable of being directly absorbed The only experiment pointing to its possibility and probability occurred some years ago in the case of a German firm who were working with this substance In order to eliminate the danger due to the inhalation of the vapour and the fine powder suspended in the air the following experiment was carried out and was narrated to me by an eye witness It consisted in applying to the men an oro nasal mouthpiece fastened on to the face with an outlet and inlet tube carried to the outer air This was fitted with valves through which the wearer inspired the fresh air and exhaled the vitiated breath Under these circumstances it seemed that there was no possible chance of the dinitro-benzene vapour or powder obtaining access to the mouth or nose, but even with this precaution the incidence of sickness in the factory was not affected and the only other channel by which the poison could get to the blood if this experiment was properly carried out must have been the skin The possibility or impossibility of absorption by the human skin of drugs in any large quantity seems to be a very difficult problem, and Schäfer[3] says that literature extending over a century indicates that the production of impartial testimony on either the affirmative or negative side has proved of no little difficulty He says that watery solutions are not absorbed. Krause maintained that ethereal and alcoholic solutions can be absorbed but Fleisher, Ritter, and Winternitz, on the other hand, have stoutly denied the possibility The application of oily solutions of certain drugs veratrine, aconitine potassium iodide, morphine, quinine, and salicylate of soda are probably quite inert, and the only exception appears to be mercurial ointment, which is undoubtedly absorbed The fine globules of mercury in mercurial ointment are forced under the skin, the black oxide by the action of the chloride of sodium forms calomel, and this in the presence of oxygen is further changed into corrosive sublimate, which in this state is readily taken up into the system. This negative evidence made me somewhat sceptical as to the absorbability of the aromatic series of compounds but when discussing the question with Mr Orsman our chemist he said that on one occasion when working with toluelidine he accidentally spilled some on his fingers, and he narrated how he at once felt the physiological effects such as faintness and giddiness which he considered due to absorption Another point is that workmen engaged in working amongst these higher fluid distillates are always very careful not to subject their hands to any prolonged immersion in them fearing the results I therefore asked Dr John Hay of Liverpool to kindly undertake the following experiments for me

CAT 1 —In the afternoon of Oct. 10th 1900 the back of a female cat was carefully shaved whilst the animal was under an anæsthetic An ointment composed of anhydrous wool fat, containing 25 per cent dinitro-benzene, was applied to the skin over an area of three square inches A piece of lint was laid over the anointed skin and the whole was covered and sealed with a gauze and collodion dressing The next day, at 10 A M, the cat was noticed to be somewhat stupid, but if startled in the slightest it jumped up in its cage and fell down stiff and rigid with its limbs extended At 1 P M on this day the cat was dying Its respirations were gasping with long intervals of quiescence. The tongue was a livid blue as were also all the mucous membranes On opening the thorax after death the lungs were observed to be pale The blood was collected It was of a dull chocolate brown tint and coagulated readily Spectroscopically it gave a dark absorption band corresponding with the meth hæmoglobin band On microscopical examination of a fresh specimen many of the red corpuscles appeared small and misshapen It was not possible to find dinitro-benzene in either the blood or the urine

As a criticism on the above experiment it might be advanced that the dinitro benzene entered the circulation through cracks and small cuts almost unavoidably produced whilst trying to free the cat s back from its down Therefore it was decided to shave the fur off three or four days before the anointing, so that any chance abrasion or cut might have time to heal

CAT 2.—On Oct 12th the fur was shaved off from the back of a fine large tabby cat, an anæsthetic being used to keep the animal quiet during shaving On the next day the skin appeared quite clean and practically free from abrasions or cuts On the 15th a 25 per cent. dinitro benzene ointment was applied to an area of one and a quarter square inches and was carefully sealed with a collodion dressing as before On the next day distinct but slight cyanosis of the mucous membrane was observed The cat appeared to be otherwise normal On the 19th the tongue and lips were markedly blue The reflex excitability of the cat was noticed to be distinctly increased. On examination of the urine it was found to contain blood The cat died on the next day whilst under an anæsthetic On examining its blood spectroscopically absorption bands similar to the meth hæmoglobin absorption bands were observed The liver showed the naked eye appearances of fatty degeneration

CAT 3 —On Oct. 20th the back of a cat was shaved and any abrasions of the skin were allowed to heal On the 23rd a piece of parchment three inches by one inch covered with 25 per cent dinitro benzene ointment was applied and sealed with collodion and gauze dressing By the 24th the collodion and gauze were quite firmly fixed and it would have been quite impossible for the cat to have transferred any of the ointment into its mouth The nose and the mucous membrane of the mouth and tongue were however, pale and cyanosed On the next day the nose and mucous membrane were still pale and bluish, but the cat otherwise appeared healthy The cyanosis was still more marked on the 26th and there was quite a deep blue colour at the sides of the tongue It was noticed to be salivating freely and there was a definite alteration in its voice On this date an anæsthetic was administered and another strip of anointed parchment was sealed on to its back. On examining the blood it was found to be altered, irregular and refractile bodies were found apparently on the red corpuscles and the corpuscles were altered in shape The corpuscles did not run into rouleaux as in normal blood The pseudometh-hæmoglobin absorption bands were distinctly present and the blood was definitely brown to the naked eye At 1 P M on the 27th the cat looked distinctly worse, there was marked salivation the nose was very pale, and the tongue was even more cyanosed The cat was constantly crying out and lying curled up at the back of its cage It was not resistive in any way and walked with some stiffness There was distinct increase in the patellar reflex The urine was highly discoloured but there was no bile The blood was difficult to obtain as the ear almost refused to bleed It was chocolate brown The alteration and irregularity in shape of the corpuscles was even more marked than on the 26th Some of the small glittering bodies were seen floating free in the plasma The cat was still alive on the 29th but looked very ill The symptoms previously mentioned were aggravated the gait was more reeling, and the cat showed a tendency to fall on to its side There was distinct spasticity of the hind legs which were lifted high up as it walked The patellar reflex were increased On the 30th the cat was apparently dying it was unable to walk and lay on its side There was marked twitching of the head and paws The patellar reflex was still increased The cat was killed Its blood was a very rich chocolate brown, and the pseudo meth hæmoglobin band was demonstrated in it The urine was almost as dark as blood and contained both methæmoglobin and also oxyhæmoglobin. No dinitro-benzene could be demonstrated in the urine or in the blood. On making a microscopical examination of the kidneys they were found to be in a condition of inflammation, probably a toxic nephritis.

---

[3] Text book on Physiology, 1898.

Dr. Hay gives the following account of an experiment performed upon himself: "On Oct. 8th, before dressing, I anointed my groins with a small portion of the 25 per cent. dinitro-benzene ointment, weight 400 milligrammes, containing 0·1 gramme of dinitro-benzene. I repeated this in the evening before going to bed. On the 9th I noticed very marked blueness about the lips and the finger nails; the tongue was also markedly blue. There were no subjective sensations. Before dressing I anointed my groins again with a similar quantity, but at 12 noon. owing to the cyanosis increasing in intensity, I carefully washed off all the ointment. At 1 P.M. the lips were a livid blue and the nails and skin generally of a deadly hue. The pulse was 100 to 120; it was regular in time and force and with its tension apparently raised and fuller. There was a feeling of fulness in the head and some throbbing headache, increased by movement. There was no obvious alteration in the urine. On cutting the thumb the blood appeared of a distinctly brown and darker colour than is normal. There was definite blurring of the oxyhæmoglobin bands, but no absorption bands with red. An examination of the urine gave negative results. Three ounces were sent to Dr. White. [The examination of the urine of Dr. Hay gave no reaction of the dinitro-benzene test. This is easily explained, as in no instance with which I (R. P. W.) am acquainted has so short an exposure to the dinitro-benzene poison ever given a reaction either in man or any animals.] At 6 P.M. the pulse was still full and bounding, from 96 to 98, regular in time and force. There were a rather metallic taste in the mouth and frontal and orbital headache, accompanied by a feeling of fulness, increased by movement, especially when running up and down stairs. Oxygen was inhaled for five minutes without any relief or alteration in the appearances of the lips and skin. The veins of the hands and the ears were full and engorged. A distinct tremor of the hands was present. On the 10th there was still some cyanosis of the lips, but not so marked as on the 9th. The headache had almost disappeared and there was no tremor. The pulse was still somewhat frequent. On the 11th my health was practically normal with the exception of a slight tendency to headache."

These experiments prove most conclusively the ease with which dinitro-benzene when in close contact with the skin becomes absorbed. It is, however, common knowledge that the skin of a cat is thinner, more vascular, and less horny than that of a man, and therefore this personal experience is of great value Facts like these, which are important, suggest the necessity of instituting experimental inquiry into the methods of operation of many of the industrial poisons—i.e , plumbism, phosphorism, mercurialism, &c.

Passing to the subject immediately before us, it would appear that given the manipulation of a certain strength of poison a corresponding amount of sickness will ensue and that the incidence of sickness among those manufacturing explosives varies with the proportion of dinitro-benzene. Handling, grinding, heating, and otherwise manipulating pure dinitro-benzene are at all times most risky and dangerous to the worker. If the process involves any possible personal contact the strictest precautions must under such circumstances be carried out. With a less percentage of dinitro-benzene in the material manipulated we have often associated a marked amount of sickness; for instance, when working with 14 parts of dinitro-benzene to 100 parts of the other ingredients our experience has given a ratio of sickness varying from 5 to 40 per cent. of the workmen immediately employed. The amount of sickness is largely affected by atmospheric conditions, such as temperature and moisture, also by the hours of work. Our experience is that with percentages under 10 and preserving the ordinary strict precautions acute cases should be non-existent. In the early days of association with the use of dinitro-benzene the dinitro was very largely contaminated with the mono-nitro-benzene and also probably with some of the toluene compounds. In recent years, with a much more carefully prepared dinitro-benzene, but with almost the same percentage of it, the incidence of sickness has been markedly lessened. The following consideration may partially explain this fact. Pure dinitro-benzene consists of colourless crystals, but through impurities the commercial dinitro-benzene is often of a darkened colour, especially when mixed with mono-nitro-benzene, and under these circumstances the men frequently object and will even refuse to work.

In a previous part of this paper it has been shown that the mono-nitro-benzene is practically inocuous to animals; it is probably also inocuous to man and if so we can only suppose that the liquid greasy mono-nitro-benzene may assist in a material degree to render the dinitro-benzene more adhesive and thereby more easily absorbed through the skin. The mono-nitro-benzene acts as a powerful solvent of dinitro-benzene just as do the fats and oils. Acting upon this thought 0·1 gramme of chemically pure dinitro-benzene crystals alone was applied to the skin of a cat sealed as in the previous manner, yet after three days no alteration had taken place in the animal. In a second experiment 0·1 gramme of chemically pure dinitro-benzene dissolved in mono-nitro-benzene was applied to the skin of another cat at the same time. In this latter cat after the same number of days' exposure to the poison cyanosis became visible. The area of exposure of both of these poisons to the skin was identical—viz., a space of two square inches. These experiments emphasise the necessity there is of some solvent to enable the poison to be carried through the skin, for had the same dose of poison been suspended in an animal fat symptoms of poison would have been very marked. It also rather suggests that the numerous oxidising ingredients associated with the dinitro-benzene in the manufacture of high explosives may have some influence upon absorption. It must not be forgotten that in the practical working of these substances particles alight upon the body where they undergo friction and pressure and are moulded into the coil and sebaceous ducts. Recently it has been proved that not only the sebaceous but also the coil glands excrete a certain amount of oil which acts as a ready solvent to the dinitro-benzene. The presence of oil on the hands, where there are no sebaceous glands, has an important bearing upon the necessity of frequent washings of all exposed surfaces of the skin. No part of the skin, except absolutely necessary, should be left uncovered by the special clothing ordered. The hair of the head should be cut close and the face have as little hair on as possible. Caps should be tight-fitting and cover as much as can be conveniently arranged.

In conclusion, we should like to advert to the necessity which exists for instituting a Government laboratory in which experiments such as we have carried out can be performed instead of leaving these points to the energy and enthusiasm of private workers.

ON THE PROPHYLAXIS OF CARCINOMA.

BY C. B. KEETLEY, F.R.C.S. ENG.,
SURGEON TO THE WEST LONDON HOSPITAL.

IF we grant that the *materies morbi* of carcinoma is most likely a living organism, the situations generally attacked by carcinoma suggest (1) that its specific cause flourishes in either the secretions or the cells of the skin-glands, including the mammary gland—e.g., milk, butter, cheese, sebaceous material, and sweat; and (2) that before milk, butter, and cheese are allowed to rest in contact with weakened parts—e.g., ulcerations—either inside or outside the body, such articles should be sterilised by heat, while the secretions of the glands of the skin should be kept away by cleanliness. It is assumed that everyone will agree that chronic inflammations of parts liable to primary cancer should be cured, if possible, and that ulcerations and cicatrices in such localities, unless there are predominating reasons to the contrary, should be removed.

Almost all primary carcinomata are seated in the breast, the alimentary canal, the skin, and the uterus, or in canals, ducts, and glands subsidiary to those parts or directly opening into them—e.g., the larynx, liver, pancreas, vagina, and urethra. The majority of those which have come under my own observation have occurred in either the breast or in the alimentary canal (including in the latter the lips and the rectum).

Reflecting on what medium would be a likely or possible carrier of the essential cause of cancer (whatever that may be) to two such different localities as the breast and any segment of the alimentary canal—e.g., the œsophagus or the pylorus—I first thought of water, which is taken by all into the stomach as drink and used by many to the breast as a cleansing medium. The possible responsibility of water is not to be lightly denied, but there are several considerations which tend to exculpate it. 1. Some sufferers from cancer of the breast had not been in the habit of applying water to it. 2. Those who had, generally used soap as well, and the use of soap and water followed by drying, would be rather more likely to remove disease germs than to implant them. 3. Water is universally used as food, but there are countries in which carcinoma of the alimentary canal is said to be very rare and others where it is very common. At the same time, and of course, it must be acknowledged that a disease-germ may exist in the water of one place, country, or continent, and be absent in another.

Now, there is another fluid very much more specially associated with both the alimentary canal and the breast than is water—viz., milk. Milk (including its products, butter and cheese) is universally used as food in such countries as England and Germany, where cancer of the stomach is common, and is, I am informed by my friend Sir William Kinsey, comparatively little used in India and Ceylon, where cancer of the stomach is very rare. An objector, while granting that a very large proportion of carcinomata (I am speaking, of course, of primary ones) affect either the breast or the alimentary canal, might point out that still a large percentage remain which are located in either the uterus or the skin. With regard to the skin it must be remembered that the breast is itself a skin-gland, and it seems to me probable that an organism which can live and multiply best in milk might yet survive and get along very well in the secretions of the sweat-glands or of the sebaceous follicles. Nor is it necessary, in order to support the view which I am calling attention to, to assume that the *materies morbi lives mainly in the milk itself. Its habitat may* be the epithelial cells which line the gland, the milk still being the carrier of the organism from the breast to elsewhere. Indeed, the great characteristic of cancerous growth—viz., the enormous multiplication of epithelial cells—suggests strongly that they are the habitat of the cancer organism. Further, the difficulty of cultivating cancer-germs in dead media points to their multiplying best in living cells and offers a possible explanation of the apparently much less frequency of direct infection from one individual to another of cancer than of tubercle. The fact that millions of persons take milk and its products as food and yet escape cancer is of no more significance than that millions of such people escape tubercle.

Cancer seems slow to infect any plain surface of skin or mucous membrane free from folds or depressions where its cause can lodge for a time undisturbed. It is rare in the urethra, which is free from transverse folds and frequently washed out by the urine. It is only, in exceptional instances even of advanced cancer of the breast that "cancer en cuirasse" occurs, and that may be due to secondary infection *viâ* the subcutaneous lymphatics. The commonest seats of primary carcinoma in the alimentary canal are obviously parts where food may lodge or adhere—e.g., the lips, the margins and under-surface of the tongue, the tonsils, the gullet behind the larynx and again where it is crossed by a bronchus, the [illegible] near to the pylorus, the pylor[illegible] the sigmoid flexure, the rectum, any part of the alimentary canal which has been the seat of chronic ulceration or of cicatricial contraction, and the lower portion of the large bowel in those curious cases of multiple polypi, which would of course tend to delay the passage of solid fæces, just as hillocks and trees check the downward course of snow on a hillside. All these facts seem to me to point to the probability of the cancer-germ being conveyed by food, but requiring time and rest to establish itself, and taking advantage of ulcerated and otherwise injured spots.

There are, it must be acknowledged, primary carcinomata arising in places which one would scarcely think of as accessible to milk and its products. There are, e.g., the laryngeal, the pancreatic, the hepatic, and, above all, the numerous uterine cancers. The larynx, the lungs, the pancreatic duct, and the bile ducts open directly or indirectly into the alimentary canal; and the uterus opens by way of a wide canal to the surface of the body. But it is possible that primary cancerous infection is sometimes conveyed *viâ* the lymphatics, just as secondary is, no tumour forming at the seat of entry, and that it then rests and multiplies at such epithelial-lined cavity as it may reach, perishing in situations where there is no epithelium. A secondary carcinoma implies that not only the cancer-germ but the epithelium in which it lives and the growth of which it so greatly excites, has been conveyed from one part of the body to another. Carcinoma of deep-lying organs, such as the brain and structures like bone, are, it is well known, generally, if not always, secondary.

While it is easy to explain the infection of a part of the alimentary tract by food it is not so easy to explain the infection of the mammary gland. The milk-ducts are obviously possible, indeed probable, channels for the conveyance of germs from the nipple to deeper parts. It seems to me that a not unlikely manner in which the nipple, or some eczematous spot on it, is infected is by the sufferer's fingers. It is true that the fingers are seldom dipped into milk and that only those of the lower classes often handle cheese. Butter, however, comes frequently into contact with the fingers of nearly all women, and it is not considered sufficiently polluting to require that the hands shall be carefully washed afterwards. When considering the possibility of water being the cancer-carrying medium I thought perhaps the nipple was infected by the linen, but linen and cotton undergo a treatment at the laundry calculated to kill any disease essence. Flannel, however, is treated more gently; still, even flannel, though not exposed to heat, is freely rubbed with soap. The mention of flannel reminds me that lanoline—a fat obtained from lamb's wool and now a favourite application to the skin—might easily prove a favourable medium for the protection, if not for the culture, of any organism which lives in sweat-glands or milk follicles.

With regard to the frequent occurrence of cancer on the hands of workers in petroleum, on the scrotum of the chimney-sweep, the lip of the pipe-smoker, and in the lungs of the cobalt-miner, it does not seem very likely that the *cancer or any other living organism would flourish in* paraffin, in carbon, in smoke, or in an ore which is a mixture of a metal with sulphur and arsenic. Such substances probably merely predispose to cancer by, so to speak, preparing the human soil, sometimes by causing a chronic eczema.

I should be exceedingly grateful to any of the readers of THE LANCET who would, either through its columns or privately, inform me of facts bearing on the possible guilt or innocence of milk, butter, or cheese in the etiology of carcinoma. I hope I shall be excused for asking gentlemen who may respond to this request (1) that the distinction between carcinoma and sarcoma shall always be carefully remembered; and (2) that any references that they may make to published sources of information shall be exact enough for verification. In particular, I think, the experience of medical men who have practised in foreign countries might prove instructive. But I am afraid that there are now few regions, not even the most remote islands, where butter and cheese are not imported, even if cows are not kept. I have endeavoured, not very successfully, to collect facts from veterinary friends. I have to thank Mr. Gresswell of Louth for a kind effort to assist and I hope that now the attention of able observers like him is called to the subject ultimately much may be learnt from them.

If my remarks should lead anyone to avoid uncooked milk, butter, and cheese, and if also it should prove in the end that those articles of diet have nothing to do with the conveyance of cancer, I think it will matter little. The danger of contracting tuberculosis is already sufficient to justify such an attitude towards those foods. It is not as if I had, e.g., suggested in an alarmist manner and without sufficient proof that cancer was caused by the practice of clothing the lower extremities, especially in winter, and that all adult males over 45 years of age would wear, at their peril, anything heavier than a short gauze-skirt. The Lord Chancellor, all Bishops, and all Fellows of the Colleges of Physicians not of Highland origin might prefer death to such indignity. But to suggest to people that they should refrain from swallowing unsterilised milk and milk-products is not an unwise thing on grounds some of which are fully acknowledged.

Throughout this paper where the word "cancer" is used it is as a synonym for carcinoma. And it is assumed (1) that carcinoma depends upon some living materies morbi; and (2) that all life can be destroyed by a moderate degree of heat applied for a reasonable time. I am afraid that both these assumptions might be disputed, but they are so far generally granted that this would not be a suitable place to recapitulate the arguments in support of them. The following rules for the prophylaxis of cancer might, therefore, be laid down safely, because even if they did not gain the end immediately desired they would attain others scarcely less valuable, just as the sons in the fable, though with all their digging they found no buried gold in the field bequeathed to them, yet gained health and rich crops.

1. Chronic inflammations, suppurations, and especially ulcerations, should not be neglected or allowed to drift. Still better, commencing troubles of the kind should be treated promptly and not allowed to become chronic. With regard to ulcerations, especially of the alimentary canal, and with regard, also, to suppurations, especially of the breast, it is to be remembered that the cicatrices left by their cure are liable to become the seat of malignant infection. It is therefore doubly desirable to cure such ulcerations and suppurations in their earliest stage, so that little or no cicatricial tissue may remain and in cases where the arguments for and against the removal, as opposed to the simple healing of an ulcer, are otherwise evenly balanced, the indication to remove a place especially liable to cancer should prompt one to excision.

2. Well-known sources of irritation of mucous membranes and of skin should be avoided—e.g., smoking when any trace of soreness is discovered in the mouth, on the tongue, or on the lips, and the habitual use of strong condiments and spices. Workers in special trades, such as chimney-sweeping, should lose no time in having the smallest cutaneous rashes or other trouble promptly cured. Among milk-products cheese is itself an irritant to mucous membranes. Some syphilitics with a tendency to ulceration of the tongue notice that a fresh attack frequently follows eating cheese.

3. A woman should allow nothing to come in contact with her nipples except smooth, clean linen, cotton, or silk, and the soap and warm water with which she washes herself. After being washed the nipples should be gently and thoroughly dried. She should not touch them with her hands or fingers at all. During lactation the nipple should be cleaned and gently dried after each act of suckling and then protected with a dry and clean covering. The nipple should not be merely withdrawn from the infant's mouth and pushed back under the mother's clothes. If wool be worn it should be sterilised by heat.

4. Whoever takes as food uncooked and unsterilised milk, butter, and cheese should recognise that he does so at the risk of introducing into his system the germs of disease, and that among these disease essences, so to call them, may be that of carcinoma.

Before any reader condemns me for publishing the above hypotheses without having submitted them to experimental proof he should bear in mind that much time and probably the coöperation of many observers would be required for such a work. Moreover, antiseptic surgery was at first based on hypotheses which were not only then unproved but which even to some extent—e.g., in the amount of blame attached to the air—were erroneous.

Grosvenor-street, W.

A CASE OF SPONTANEOUS GANGRENE IN AN INFANT.

BY T. ARMSTRONG BOWES, M.D. CANTAB.

ON March 25th, 1901, a vigorous primipara was delivered of a full-term living male child. He was to all appearances in perfect health, though a little thin, and took the breast well. About April 7th he had thrush, from which he made a satisfactory recovery. On the 10th the child was noticed to be peevish and had lost flesh. He would not take the breast, but beyond this nothing amiss could be discovered and his temperature was normal. The umbilicus was perfectly healed. On the morning of the 11th a small vesicle was noticed in the centre of the back in the lower lumbar region, and when first seen in the evening this had become a small pustule, not larger than a hempseed, with a slightly raised, rather dusky red area of the size of a florin surrounding it. Careful inquiry failed to elicit any history of traumatism. By the following morning the pustule had burst, leaving a small circular ulcer, and the red area had spread considerably upwards but not so much downwards. In the evening the redness round the ulcer had become of a deep mulberry colour, which was unaltered by pressure. The red zone had increased and in addition the umbilicus and some of the finger-tips presented small red excoriated areas. During the night the ulcer discharged a considerable quantity of thin, slightly sanguineous, odourless serum. On the morning of the 13th the almost black area extended from one inch round the seat of the original pustule. The surrounding dusky area had reached half way up the shoulder blades and the circulation in it was extremely slow. By the evening the inner darker area was three inches in diameter, the skin commencing to peel off in the centre. The child had been very fretful all day, but had taken his food. The outer dusky area now reached to the upper level of the scapula. On the morning of the 14th a photograph of the child was taken. It showed a dark irregular patch of considerable extent at the site of the original lesion where the skin was actually sloughing. From this extended a black and dark purplish area upwards to the scapulæ, outwards to the flanks, and downwards over the sacrum, gradually shading off to lighter dusky red to involve the neck, the posterior portions of the shoulders, the outer portions of the chest and abdomen, the whole of the buttocks, and the outer part of the thighs. The photograph showed the lighter unaffected skin of the upper arm and lower portion of the thigh towards the knee, but it failed to portray the variety in colour and the gradually shading of the skin involved in the affection. The superficial abdominal veins were of a light claret colour and the abdominal viscera showed as a dusky background to the dull, lifeless-looking, inelastic pallid skin of the abdominal walls. The child gradually sank and died the same evening. Throughout the whole duration of the case the temperature never rose above normal and at death the red excoriated areas on the fingers and at the umbilicus had not become deeper in colour and had only increased very slightly in extent. No post-mortem examination was permitted.

The absence of traumatism or of any previous disease or cachexia points to the above case as one of spontaneous gangrene. According to Keating[1] gangrene in infants, excluding noma and cancrum oris, occurs either spontaneously or as a concomitant or sequel to various diseases, such as pemphigus, syphilis, varicella, measles, erysipelas, &c. The spontaneous form is stated to occur at any age up to late childhood and although sometimes affecting children to all appearances perfectly healthy is more usual in those suffering from debility or cachexia. It may attack any portion of the body, the onset being severe with raised temperature, becoming depressed as the disease advances. It may be symmetrical or commence synchronously at several different foci, or as in the above-narrated case start from one isolated spot. The prognosis is very grave. The only suggested cause is spasm of the arterioles of the affected area, and it appears doubtful as to whether this be of central or of peripheral origin, though changes in the spinal cord have been described in some cases wherein the disease has been symmetrical. The cause of the cases following the diseases above enumerated is suggested as a local infection by the microbes of the disease in the presence of a lowered vitality of the subject.

The literature relating to the disease is scanty and after careful search I have been able to find records of four cases only which bear a resemblance to the one I have detailed. Reed[2] describes a case of gangrene of the leg, thigh, and foot in an infant 14 days old, commencing below and outside the knee, without any evidence of injury; no embolism or thrombosis of the femoral artery was found at the post-mortem examination. From the description it is probable that the case was not seen till the gangrene was well-established and there is no evidence as to how the disease began or advanced in its earlier stages. Manley[3] describes an ante-partum gangrene of the legs and thighs in a child living at birth and surviving for 24 hours after, but unfortunately there was no post-mortem examination of this case, in which the skin was actually peeling from the buttocks when the child was born. Norman[3] records a case of idiopathic gangrenous erysipelas in which the initial lesion was a blister resembling a burn on the left forearm and from which the arm, chest, and greater portion of the back were all involved in a gangrenous process within three days. And, lastly, the *Medical Press and*

[3] THE LANCET, Dec. 15th, 1888, p. 1173.

Circular[4] gives an account of a case exhibiting numerous foci of invasion, commencing as small papules, followed by blisters, and resulting in ulcerations reaching the diameter of half-a-crown, the duration of the case being 11 days from commencement to a fatal termination.

The case I have described appears worthy of record from its apparent rarity, from the absence of any severe initial symptoms, the fact that the temperature was never raised above normal, and from the extreme rapidity with which so large an area of skin was involved, the whole duration from commencement to the fatal issue being only three and a half days.

Herne Bay, Kent.

HOSPITAL CAMP SANITATION IN SOUTH AFRICA.

BY BURTON A. NICOL, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE CIVIL SURGEON ATTACHED TO THE ROYAL ARMY MEDICAL CORPS, NATAL FIELD FORCE.

IN my experience as civil surgeon on the staff of two of the large general hospitals in South Africa I was much impressed with the large amount of sickness prevalent among the orderlies on the hospital staff. As these men are to some extent trained to recognition of the risks of infection and to methods of cleanliness and disinfection one would not expect a very large incidence of disease among them in spite of their exposure to so many risks. They have also, at least in my experience, availed themselves of the advantages of inoculation against enteric fever in a much greater proportion than the ordinary soldier, so that if this has been a benefit it ought to have helped towards reducing disease in their ranks. I have no figures to quote from, but I know that at Estcourt during the first few months of the work of No. 7 General Hospital the nursing of the sick was hampered greatly by the amount of sickness prevalent among the orderlies. To such an extent was this so that in the first four months about one-third of the orderlies who were originally attached to the hospital staff had passed through the wards; most of them had enteric fever, a smaller number suffering from dysentery or diarrhœa of a dysenteric type. At Newcastle (No. 14 General Hospital) there was also a considerable amount of sickness among the orderlies. At first it was not so marked as at Estcourt, but it should be pointed out that the proportion of fever cases in [illegible] the disease apparently [illegible]e cases were practically [illegible]rly large proportion of severe cases

My attention was thus drawn to the general sanitary condition of the camps and to the precautions which were being taken to prevent the spread of contagion from patients to those whose duty it was to look after them and restore them to health. At No 14 General Hospital at Newcastle printed rules were circulated among wardmasters and orderlies as to their duties with regard to the management of infectious cases, the treatment of excreta, &c. The following is a summary of the observances laid down for their guidance in these regulations and of the general methods employed. Kaffirs at both hospitals were employed as ground scavengers and kept the camp beautifully clean, picking up every scrap of paper, wood, and other refuse. These men, however, would have nothing to do with the handling of excreta, so that this was all dealt with by Indians specially employed for the purpose. It was very fortunate that these men were available, as our men were thus able to devote themselves entirely to their nursing duties. When an orderly had placed the night-stool, chamber-pot, or bed-pan containing an enteric or dysenteric stool outside the tent one of these ward Indians at once picked it up and carried it to the enteric fever enclosure where it was emptied into the excreta buckets. It was then washed out with 1 in 800 corrosive sublimate solution, some izal solution (1 in 20) was placed in it, and the utensil was at once returned to the ward. The excreta buckets were kept covered and when three-fourths full were taken to the incinerator, where the contents were boiled down to dryness, mixed with sawdust, and then burnt. The urine was supposed to be treated in the same way, but I am afraid that careless orderlies were frequently in the habit of emptying urinals into slop-buckets, which were in turn emptied into separate sanitary handcarts (large zinc drums on wheels). It thus often escaped thorough disinfection.

The soiled linen was always removed in red handcarts from the wards, being first sprinkled with carbolic solution, 1 in 20; it was taken to the enteric fever enclosure, placed [illegible] minutes, dried, and then taken to [illegible]ent to the wash. All mattresses, [illegible]t would have been destroyed by [illegible] in Thresh's steam disinfector. Excreta and all linen from dysentery wards were treated in exactly the same way as if coming from an enteric fever ward. All bed-pans, night-stools, urinals, and slop-pails belonging to enteric fever wards were marked with the letter "E" in red paint and kept apart in every possible way from similar utensils in other parts of the hospital. They were always kept outside the wards at one particular corner of the tent or marquee. The Indians employed in this sanitary work were used only for removing excreta, slops, and rubbish from the wards, they were not employed on any ordinary fatigue work, such as carrying water, food, &c., or cleansing utensils for food or drink. They were on duty at all times, so that at night the removal of stools from the precincts of the wards was carried out as promptly as in the day. The enteric fever enclosure was in charge of a non-commissioned officer and he was responsible for the carrying out of all details in connexion with the work of disinfection. He was assisted in his work by one European and three Indians. The floor of this enclosure was of cement; it was cleaned daily and washed with sublimate solution 1 in 800. Every ward was supplied with a bottle of carbolic solution, 1 in 20, no special bottle was, however, provided and a brandy or other similar bottle was invariably used. This was dangerous, as the wards were not provided with any receptacle where it might be safely and conveniently kept. Orderlies were instructed after handling patients or infected articles and before meals to wash their hands in carbolic solution, 1 in 20, and to use a nail-brush. This order was [illegible] towels, [illegible]vance of [illegible]ys were kept for enteric fever wards and were all marked with the letter "E."

It will thus be seen that a fairly comprehensive scheme was arranged for the proper treatment and disposal of refuse and infected material and for the prevention as far as possible of the dissemination of disease. Many other points were neglected, and it is possible that a closer attention to detail would have improved upon the general results obtained. No general sanitary officer was appointed to exercise supervision over the details laid down in the scheme. This work was divided among the various civil surgeons and Royal Army Medical Corps subalterns, each one acting in turn as sanitary officer for one week; the work was certainly not done as thoroughly as would have been the case had it been the duty of one man to superintend closely all the details of sanitary work in the neighbourhood of the camp. The orderlies were very inexperienced in hospital work—the majority of them could not be made to understand the gravity of the risks they were running by carelessness with regard to personal cleanliness. They were being constantly changed from ward to ward, so that before a man had time to benefit by the instructions of the nurse and medical officer he was removed to non-fever wards and another novice supplied in his place. They were frequently put on night duty at the end of what was always a long and heavy day's work. This must have acted disadvantageously on their general health, increasing their risks of infection by lowering their resistance to disease. Orderlies, whose work lay entirely in non-fever wards during the day, or even in the office, would be sent into a fever ward for night duty. The disadvantages of such a proceeding to both orderly and patients are very obvious.

Great attention was paid to apparent cleanliness, to such an extent that hardly a straw or burnt match end could be seen in the neighbourhood of the camp; slop water that had been used for washing enteric fever patients was, however, frequently thrown out over the ground instead of being carried away. I have seen a trained nurse do this, and the orderlies frequently did it. It is a very difficult practice to detect and check. Convalescent patients and orderlies were in the habit of micturating on the ground after sunset in portions of the camp when they were likely to be unobserved instead of going to the latrine. The ground was thus fouled in many ways, though apparently clean.

---

[4] Medical Press and Circular, vol. ii., 1889.

There was a scarcity of ward utensils, drinking-cups, tumblers, &c., so that these articles were frequently used in common. No proper arrangements were ever made for storing milk, beef-tea, &c., in the wards. Dishes, forks, knives, spoons, &c , were often not so thoroughly cleansed as they should have been, as this work was done in the wards or immediately outside, which was objectionable. The milk for fever cases was served out three times a day, a pint at a time. This was placed in each patient's bowl on his bedside table; the bowl thus served the double purpose of a drinking-cup and a basin for storing the milk. The consequence of this was that thirsty patients either helped themselves to a large quantity at a time and then waited without food for many hours until the next pint came, or if at all typhoidal neglected it, and it became the food-supply and a death-trap for all the flies in the ward. Patients convalescent from enteric fever and dysentery often used latrines in common with other patients. Efforts were made to prevent this. The urine from enteric fever patients undoubtedly often escaped the thorough disinfection it should have received.

The greatest defect of all in this camp was certainly a very deficient water-supply. The town of Newcastle had for some years found their water-supply insufficient for their own needs and were considering various schemes for improving the supply. With a large general hospital of 520 beds and a very large number of troops quartered in this district the deficiency became suddenly acute. To make things worse the year 1900 was rather dry and the rains came very late in the season. Pipes were laid on over the hospital camp and connected with the town supply; they were, however, usually empty. Water could sometimes be obtained from the pipes for about an hour early in the morning; later in the day it had almost invariably to be carried from a standard at the railway station, which was situated at a slightly lower level than the hospital. A great deal of water was carted in water-carts drawn by mules or oxen. This was unsatisfactory as the carts were of the wooden barrel on wheels type; they were difficult to keep sweet and clean. They were at one time discovered to be very foul. The men complained that the tea was unpalatable and alleged that the water gave them diarrhœa. The deficiency was so serious that no one could understand why the site was not condemned at once for hospital uses, for it was quite impossible to keep patients in that condition of cleanliness which everyone agrees is essential in a hospital, especially where there was a large proportion of enteric fever cases. A regulation existed that all patients who were sufficiently well should receive a hot bath before admission to the ward. They could not have even a cold bath; the carrying of such water as was used from the carts to the wards greatly increased the amount of work done by the orderlies, and must have discouraged its free use. Nice wash-houses had been erected for the use of convalescent patients, they were filled with rows of bowls with water laid on for each bowl. I never saw water in them except in the very early morning and sometimes not then

The quantity of soda-water obtainable was limited by the deficiency of water in the town, the supply being a purely local one. We could not obtain it for our fever cases in the quantity which we thought necessary, the amounts were again and again cut down. It was noticed that although the hospital could not get the quantity of aerated water it wanted the hotels in the town were never short. The water used by orderlies and patients for drinking purposes was neither filtered nor boiled, that used in the wards was kept in canvas water-coolers outside the tents, to which the dust readily obtained access, The water-supply at Estcourt, I may say, was very good.

The sites were, I believe, usually well chosen. The hospital at Estcourt was in a particularly good position on the slope of a small hill. It was near the railway, so that a special siding was constructed by which means the hospital trains were run right to the bottom of the camp. At Newcastle, however, we were occupying a site which had been used for some months by one of the stationary hospitals before our arrival; it was on a low piece of ground near the river and was much too close to the town. The consequence was that flies were much more troublesome than at Estcourt; the camp, though near the station, had no siding of its own and its position in other respects was undesirable.

I feel certain that a more careful selection of hospital sites might have been made in certain cases, and with a closer supervision over some of the details of sanitary work would have saved a great deal of the sickness among the hospital staff. In this way both directly and indirectly the efficiency of the hospitals would have been increased. The authorities did not seem to recognise the fact that a continued use of one particular site was disadvantageous from the consequent fouling of the ground which was being continually carried on when a large number of enteric fever cases were brought together. The great advantage of a canvas hospital is its mobility; this advantage is lost where one site is persistently used for many months in spite of obvious and very serious defects. Some light is also thrown upon the value of the investigations made by the recent Hospital Commission in their flying tour through South Africa when it is remembered that Newcastle was one of the towns visited by them and witnesses were there examined. No comment, so far as I know, has been made by them upon its water-supply, and the hospital, I believe, still exists upon the same site.

ON THE BEHAVIOUR OF OXY-HÆMOGLOBIN, CARBONIC-OXIDE-HÆMOGLOBIN, METHÆMOGLOBIN, AND CERTAIN OF THEIR DERIVATIVES, IN THE MAGNETIC FIELD,

WITH A PRELIMINARY NOTE ON THE ELECTROLYSIS OF THE HÆMOGLOBIN COMPOUNDS.[1]

By ARTHUR GAMGEE, M.D. EDIN., F.R.S.,
EMERITUS PROFESSOR OF PHYSIOLOGY IN THE OWENS COLLEGE, VICTORIA UNIVERSITY.

I.—THE OBSERVATIONS OF FARADAY AND PLÜCKER ON THE DIAMAGNETIC PROPERTIES OF THE BLOOD.

IN the course of his investigations on magnetism and diamagnetism, read before the Royal Society in the year 1845, Faraday[2] found that, notwithstanding the iron which its colouring matter contains, the blood is a diamagnetic liquid. "I was much impressed," he remarked, "by the fact that blood was not magnetic, nor any of the specimens tried of red muscular fibre of beef or mutton. This was the more striking because, as will be seen hereafter, iron is *always* and in almost all states magnetic. But in respect to this point it may be observed that the ordinary magnetic property of matter and this new property are in their efforts opposed to each other; and that when this property is strong it may overcome a very slight degree of ordinary magnetic force, just as also a certain amount of magnetic property may oppose and effectually hide the presence of this force."[3] Faraday further found the blood to behave like all the constituent tissues of animal bodies which he investigated and was led to state that "if a man could be suspended with sufficient delicacy, after the manner of Dufay, and placed in the magnetic field he would point equatorially, for all the substances of which he is formed, including the blood, possess this property."[4] De la Rive and Brunner,[5] later, suspending a bound-up frog between the poles of an electro-magnet, observed it to assume an equatorial position, thus realising Faraday's prediction that a complex animal organism must be diamagnetic in accordance with the properties of its constituent tissues and of the water which enters so largely into their composition. Shortly after the publication of Faraday's researches on diamagnetism Professor Plücker[6] of Bonn, in a well-known paper which appeared in 1848, after describing the characteristic behaviour of magnetic and diamagnetic liquids contained in watch-glasses placed upon and between the poles of power- [illegible] the results of his observations on [illegible] of the blood. He not only con- [illegible] the blood of the frog, of man, [illegible] of Faraday's statements, but by employing the microscope in his observations he was able to show that the blood corpuscles are more strongly diamagnetic than the liquid in which they float.[7]

[5] De la Rive and Brunner's researches are only known to me at second hand from the account given of them in Valentin's "Grundriss der Physiologie" (4 Auflage, 1855, p. 507), where an engraving is reproduced in which a bound-up frog is shown placed between the poles of the electro-magnet.

[6] Experimental Untersuchungen über die Wirkung der Magnete auf gasförmige und tropfbare Flüssigkeiten. Refer to the heading, "Über das magnetische und diamagnetische Verhalten der tropfbarflüssigen Körper," in "Poggendorff's Annalen der Physik und Chemie," vol. lxxiii., 1848, para. 49, p. 575.

II.—OBJECTS OF THE PRESENT INVESTIGATION.

At a time when all facts bearing on the physical properties and the chemical relations and structure of the blood-colouring matter are rightly claiming the attention of many of the leading workers in physiological chemistry it appeared to me very desirable to examine the magnetic properties of the crystalline blood-colouring matter itself, in the condition of utmost available purity, and, whatever the results might be, to extend the inquiry to its leading [illegible] shown that the blood is dia- [illegible] at the blood corpuscles are more decidedly diamagnetic than the liquid in which they float, it was yet conceivable, though improbable, that the iron-containg hæmoglobin would prove to be a feebly magnetic body, of which the true magnetic behaviour was concealed by the substances with which it is associated in the blood corpuscles. Whether hæmoglobin proved to be magnetic or diamagnetic it obviously would be of great interest to examine the magnetic properties of the iron-containing substances which the blood-colouring matter yields when it is decomposed by acids in the presence of oxygen, and in the event of a difference between the magnetic behaviour of the mother-substance and its derivatives to push the inquiry in a direction likely to lead to the discovery of the cause of the discrepancy. In pursuance of such an object I have been led to inquire whether the pure blood-colouring matter in aqueous solution is an electrolyte, and having discovered that it is one to examine the results of its electrolysis. On this part of my inquiry the statements which I have to make in this paper are strictly preliminary, and, except in the first most interesting particular that oxy-hæmoglobin and CO-hæmoglobin separate in the first instance from their aqueous solutions when these are subjected to very feeble currents, are to be considered as liable to correction by future more extended work.

III.—THE ELECTRO-MAGNET EMPLOYED IN THE PRESENT RESEARCH.

The electro-magnet employed was constructed by Ladd many years ago and is sufficiently powerful to be employed for observations on the rotation of the plane of polarisation of light. I had it fitted with an accurately closing glass case and, with adequate arrangements for the proper suspension of the bodies under examination. I am not possessed of instruments which would enable me to determine directly the strength of the magnetic field employed in my several sets of experiments. The Rev. F. J. Jervis-Smith, F.R.S., Millard Lecturer in Experimental Mechanics in the University of Oxford, to whom I had the pleasure of showing my experiments, had the great kindness to make careful measurements of the coils and has practically reconstructed an electro-magnet similar in dimensions to mine, with the same windings, and of which the iron core derived from a similar instrument made by Ladd was probably identical in properties to that in my electro-magnet. Using Professor Rowland's method for determining the field he obtained the following results. Intensity of the earth's horizontal magnetic component at Oxford = 0·18. Distance between faces of pole pieces, three centimetres. Current in ampères, 2·4, 3·3, 4·2; magnetic field in C.G.S. units, 516, 700, 870. Probably it is safe as an approximate estimate to assume that my field was about 1000 C.G.S. units with a current of five ampères.

All the fundamental experiments on the magnetic properties of oxy-hæmoglobin, CO-hæmoglobin, and methæmoglobin were made by suspending cakes of the dried crystalline bodies by means of one or a few fibres of silk between the poles, thus avoiding the disturbing influence of glass tubes, however feebly magnetic. In the case of hæmin the substance was similarly examined, in the first instance by suspending as far as possible rectangular cakes formed by the aggregation of crystals. In the case of hæmatin the substance, being in an amorphous pulverulent condition, was necessarily examined in glass tubes, but its intensely magnetic properties prevented in its case, as in that of hæmin, any difficulties arising from the very feebly magnetic properties of the glass tube containing it.

IV.—OXY-HÆMOGLOBIN A STRONGLY DIAMAGNETIC BODY.

The oxy-hæmoglobin employed in the present research was prepared by myself during the past winter from the blood of the horse by employing substantially the method of Hoppe-Seyler. In some cases the blood corpuscles were separated from the defibrinated blood by long-continued centrifugalising; generally, however, the defibrinated blood was mixed with 10 times its volume of a mixture made by diluting 10 volumes of saturated NaCl solution with 90 volumes of distilled water and the corpuscles were then separated by means of the centrifuge.

In either case the magma of corpuscles was treated with a small quantity of distilled water and pure ether, and the mixture having been thoroughly agitated in a stoppered separating funnel, the aqueous solution of the blood-colouring matter was separated and filtered into flasks surrounded with ice, and subsequently treated with one-fourth of its volume of pure absolute alcohol at a temperature of – 5° C, and the mixture placed in an ice chamber for 24 or 36 hours. The oxy-hæmoglobin which crystallised was separated from its mother-liquor by means of the centrifuge. The crystalline mass was repeatedly washed with distilled water at 0° C. and the washed crystals treated with distilled water at 30° C.; the saturated solution was rapidly centrifugalised, rapidly filtered into flasks surrounded by ice and salt, and the hæmoglobin caused to crystallise by the addition of absolute alcohol under the prolonged influence of cold. After being crystallised three times the oxy-hæmoglobin was collected on filters and the moist mass of microscopic crystals drained. The pasty crystalline mass was dried *in vacuo* over sulphuric acid at a temperature which never exceeded 5° C

Behaviour in the magnetic field.—An irregular mass of three times crystallised oxy-hæmoglobin dried *in vacuo*, weighing 1·088 grammes, and measuring 18 millimetres in length, 13 millimetres in depth, and 13 millimetres in breadth, was suspended by a couple of fibres of unspun silk between the poles of the magnet, the distance between these being 20 millimetres; the mass was made to rest in the axial position before the current was passed through the coils.

Three cells of an accumulator were employed; on closing the key the mass of hæmoglobin instantly assumed the equatorial position. The experiment was repeated with masses of hæmoglobin prepared at various times and re-crystallised from one to three times, and weighing from 0·5 to 2 grammes, and invariably they were found to be powerfully diamagnetic.

A specimen of oxy-hæmoglobin of the horse, kindly prepared for me under the direction of Professor Hofmeister in the Chemico-Physiological Laboratory of the University of Strasburg by the ammonium-sulphate method, and which had been five times crystallised, proved to be as powerfully diamagnetic as the oxy-hæmoglobin prepared by Hoppe-Seyler's method.

V.—CARBONIC-OXIDE-HÆMOGLOBIN IS, LIKE OXY-HÆMOGLOBIN, STRONGLY DIAMAGNETIC.

Mode of preparation.—The carbonic oxy-hæmoglobin employed was prepared by saturating a concentrated solution of twice crystallised oxy-hæmoglobin with pure CO, and then crystallising the CO compound by the addition of absolute alcohol and exposure to a temperature of – 5—10° C.

Behaviour in the magnetic field.—A nearly rectangular prismatic mass of CO-hæmoglobin which had been dried *in vacuo*, and which weighed 0 642 gramme, and of which the length was 17 millimetres, the breadth 6·5 millimetres, and the depth 13 millimetres, was brought into the axial position between the poles of the electro-magnet, the distance between these being 18 millimetres. On passing the current from three cells of an accumulator through the coils of the electro-magnet the mass instantly assumed the equatorial position. The experiment was repeated with different specimens of CO-hæmoglobin and invariably with the same result.

---

[7] In 1874, Dr. R. C. Shettle, in a paper read before the Royal Society [illegible] they are entirely erroneous.

In the absence of all data as to the diamagnetic moment of either oxy- or CO-hæmoglobin it is impossible to state whether these bodies differ in any degree in respect to their behaviour in the magnetic field. Working carefully but merely qualitatively it would appear, however, that their behaviour in the magnetic field is identical.

VI.—METHÆMOGLOBIN IS, LIKE OXY-HÆMOGLOBIN, STRONGLY DIAMAGNETIC.

The substance was prepared by adding to a saturated solution of twice crystallised oxy-hæmoglobin of the horse a few drops of solution of ferricyanide of potassium until the characteristic change in colour and in the spectrum indicated the complete conversion into methæmoglobin. The solution was cooled to – 5° C., treated with one-fourth of its volume of absolute alcohol at – 10° C., and the mixture placed in ice and salt for a period of 36 hours. The crystalline methæmoglobin which separated was then washed with repeated quantities of ice-cold water, collected on a filter, drained, and dried *in vacuo* at a temperature not exceeding 5° C. Experiments with lumps of this substance varying in weight between 0·3 and 1·0 gramme showed it to be apparently as diamagnetic as oxy-hæmoglobin.

VII.—HÆMATIN AND ACETHÆMIN (HÆMIN)—INTENSELY MAGNETIC SUBSTANCES.

Preliminary remarks.—The more recent analysis of Jaquet, Zinoffsky, and Hüfner have led to the conclusion that, at any rate in the horse, the dog, the ox, and the hen, there exists a remarkable constancy in the proportion of the iron which exists in hæmoglobin (0·335 per cent.).[8] If it be assumed that one molecule of hæmoglobin contains one atom of iron, the molecular weight of the hæmoglobin of the dog, the horse, the ox, and the hen would be 16,669, a result which concords admirably with the volume of oxygen and carbonic oxide which can enter into combination with hæmoglobin on the assumption (first of all advanced by Lothar Meyer) that one molecule of hæmoglobin can combine either with a molecule of oxygen or of carbonic oxide. The empirical formula for the hæmoglobin of the dog calculated by Jaquet from his analysis is probably very near the truth—namely, $C_{758}H_{1203}N_{195}S_3FeO_{218}$.

Why should hæmoglobin possess so enormously high a molecular weight? The question suggested itself to Bunge who has furnished us with a reason which is eminently suggestive. "The enormous size of the hæmoglobin molecule," says this writer, "finds a teleological explanation, if we consider that iron is eight times as heavy as water. A compound of iron which would float easily along with the blood current through the vessels could only be secured by the iron being taken up by so large an organic molecule."

When oxy-hæmoglobin is subjected to the action of acids and alkalies it splits up with great ease into a coloured iron-containing body and into an albuminous body (or mixture of such bodies). The former, to which the name of "hæmatin" has been given, is a derivative of the molecule group existing in the blood-colouring matter, upon which its colour, its spectroscopic characters, and its physiological properties doubtless depend, though it is a derivative which is unquestionably a product of oxidation, and in no sense represents the real hæmochromogen. According to Hoppe-Seyler the empirical formula of hæmatin is $C_{31}H_{35}O_5N_4Fe$, whilst according to Nencki its composition is represented by the formula $C_{32}H_{32}O_4N_4Fe$.

When the decomposition of oxy-hæmoglobin is effected by glacial acetic acid in the presence of alkaline chlorides a perfectly crystalline substance separates which has been hitherto known under the name of *hæmin*, but which we shall now, following the suggestion of Nencki, term *acethæmin.* This body was looked upon by Hoppe-Seyler as a hydrochloride of hæmatin; the recent researches of Nencki and Zaleski have shown that acethæmin contains 8·59 of iron, and possesses a composition represented by the formula $C_{31}H_{33}O_4N_4ClFe$; it contains an acetyl group, and both the acetyl and chlorine in it are linked to the iron. When this body is dissolved in weak solutions of sodium hydrate in the cold the chlorine and acetyl are separated, and on neutralisation with acids hæmatin of composition $C_{32}H_{32}O_4N_4Fe$ is obtained. It is with these two coloured iron-containing decomposition products of hæmoglobin, hæmatin and acethæmin, that my observations have been carried out. Before referring to these in detail I wish again to insist that these oxidation-products in no sense represent the unaltered iron-containing group to which the blood-colouring matter owes its physiological properties. As Hoppe-Seyler showed, when hæmoglobin is decomposed by acids and alkalies *in the absence of all traces of oxygen*, hæmatin is never formed, but a colouring matter which possesses the same spectrum as that which had previously been described by Stokes as that of reduced hæmatin. This substance Hoppe-Seyler called hæmochromogen, and he expressed the opinion that it constitutes the veritable coloured radical upon which the physiological properties of hæmoglobin depend. The experimental facts advanced by Hoppe-Seyler have always appeared to me absolutely inadequate to warrant this hypothesis, which, however, is most suggestive and demands a thorough and a new investigation.

A. *Magnetic properties of acethæmin.*—The acethæmin employed in the present research was prepared by me from ox's blood by the method of Schalfijew. Some of the specimens were purified by re-crystallisation from glacial acetic acid, others by dissolving in a chloroformic solution of pure quinine, and subsequently adding to the filtrate hot glacial acetic acid, saturated with NaCl.[9] My first observations were made with a block of agglomerated hæmin crystals weighing 0·6455 gramme and measuring 26 millimetres in greatest length, 18 millimetres in height, and six millimetres in thickness; this block was suspended by two fibres of silk, so as to occupy the equatorial position in reference to the pole pieces of the magnet. The distance between the poles being 30 millimetres, on passing a current from three accumulator cells through the coils the mass instantly assumed the axial position and was strongly attracted to the nearest pole, the suspending silk fibres being sensibly deflected from their original vertical position. Even when the poles of the electro-magnet were 40 millimetres apart the mass instantly set in an axial position when the current was passed. The observations were repeated with numerous specimens of hæmin and always with similar results.

B. *Magnetic properties of hæmatin.*—The hæmatin employed in these researches was prepared by dissolving re-crystallised and perfectly pure acethæmin in a weak solution of chemically pure sodium hydrate at ordinary temperatures, and precipitating the filtered solution without delay by neutralising with dilute sulphuric acid. The precipitated hæmatin was thoroughly washed, drained, and dried. In consequence of its absolutely amorphous pulverulent character my magnetic observations on this body were conducted with the aid of tubes of very feebly magnetic glass, containing from 0·1 to 0·4 of pure hæmatin. The intensely magnetic character of hæmatin was as easily demonstrated as had been that of acethæmin.

VIII.—THE ELECTROLYSIS OF SOLUTIONS OF PURE OXY-HÆMOGLOBIN AND CO-HÆMOGLOBIN.

Preliminary observations.—The remarkably definite results of my research, which had shown that oxy- and CO-hæmoglobin are decidedly diamagnetic substances, whilst their iron-containing derivatives, acethæmin and hæmatin, are powerfully magnetic, naturally led me to speculate on the possible cause of these differences. It appeared to me that if hæmoglobin were found to be an electrolyte, apart from the interest which would attach to the discovery of the fact, a study of the products of its electrolysis might throw great light upon the question. Do we not know, for instance, that those compounds in which iron and other magnetic metals are present in electro-negative radicals are diamagnetic?[10]

In spite of my having made great efforts to purify as completely as possible the substances with which I worked it is questionable whether their purity was sufficient for electrolytic researches. The experiments which I have yet made on this division of my subject must therefore be looked upon as strictly preliminary, and I hope in the course of the coming winter to extend them greatly, making use of compounds of hæmoglobin which have been subjected to far more frequent re-crystallisation. In the course of these experiments, *beside studying the proximate products of* electrolysis with currents of different strength and potential, I intend to determine by the methods of Kohlrausch and Ostwald, with as great accuracy as possible, the specific conductivities of solutions of oxy- and CO-hæmoglobin.

---

[8] For a discussion of all the more recent analysis of hæmoglobin see my article on "Hæmoglobin" in Schäfer's "Text-book of Physiology," p. 199 et seq.

[9] Refer to my previously quoted article in Schäfer's "Text-book of Physiology," and to Nencki and Zaleski's recent article, "Untersuchungen über den Blutfarbstoff. 1. Ueber die Aether des Hämins," Zeitschrift fur Physiologische Chemie, vol. xxx., 1900, p. 384 et seq.

[10] Miller: The Elements of Chemistry, Part I., "Chemical Physics," London, 1855, p. 422; H. du Bois: Propriétés Magnétiques de la Matière Pondérable, Rapports Présentés au Congrès Internationale de Physique Réunis à Paris en 1900, Paris, 1901, tome ii., p. 460.

The following are the results of my electrolytic experiments which I wish at present to place on record. Firstly, when solutions of pure oxy-hæmoglobin are subjected to electrolysis at a temperature of about 15° C. between platinum electrodes, from 12 to 16 cells of a carbon zinc bichromate battery being employed, and the current passing through the liquid being from three to five milliampères, a rapid subsidence of the colouring matter takes place, the upper layers of the solution becoming perfectly colourless. The depositing colouring matter retains the spectroscopic character of oxy-hæmoglobin and when stirred with it is absolutely and almost instantaneously soluble in the liquid from which it has separated. Exactly the same result occurs in the case of carbonic-oxide-hæmoglobin. Secondly, on continuing the passage of the current through the solution in which precipitation has occurred secondary reactions occur, gas is developed both at the anode and cathode, and in many cases a dirty white-brown deposit forms at the cathode. Thirdly, under conditions of strength of current and potential which were not determined with sufficient accuracy and which I have not yet been able to reproduce at will the solutions of oxy-hæmoglobin and CO-hæmoglobin have, under the long-continued action of the current, on several occasions deposited at the anode an insoluble red colouring matter containing both the albuminous and the iron-containing residues of hæmoglobin. In the case of CO-hæmoglobin the compound deposited has presented the peculiar colour of CO-hæmoglobin.

IX.—GENERAL CONCLUSIONS.

The following are the conclusions to which I have been led by my experiments:—1. The blood-colouring matter, oxy-hæmoglobin, as well as carbonic-oxide hæmoglobin and methæmoglobin, are decidedly diamagnetic bodies. 2. The iron-containing derivatives hæmatin and acethæmin are powerfully magnetic bodies. The differences in magnetic behaviour between the blood-colouring matter and acethæmin and hæmatin point to the profound transformation which occurs in the hæmoglobin molecule when it is decomposed in the presence of oxygen. 3. The preliminary study of the electrolysis of oxy-hæmoglobin and CO-hæmoglobin renders it probable that in the [illegible] taining group, on which [illegible] is (or is contained in) an [illegible] to analogy the iron in [illegible] diamagnetic and not magnetic properties.

In conclusion, I beg to acknowledge my indebtedness to Professor von Bunge of Basel, to Professor Franz Hofmeister of Strasburg, and to Dr. von Ehrenberg, the technical director of the chemical factory of Messrs. Merck of Darmstadt, for their great courtesy and kindness in placing at my disposal preparations of hæmoglobin prepared by themselves or under their direction.

Montreux, Switzerland.

TONSILLOTOMY RASH.[1]

BY WYATT WINGRAVE, M.D. DURH.,
PHYSICIAN AND PATHOLOGIST TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL; CORRESPONDING FELLOW, AMERICAN LARYNGOLOGICAL ASSOCIATION.

THE occurrence of a skin eruption following operations, often referred to as "surgical rash," is familiar to all of us, but its association with the removal of tonsils and adenoids is, perhaps, not so widely recognised but that a few notes may be of interest. Recent experience of several instances prompted a reference to my hospital and private records which has revealed 34 cases in the course of seven years. Although relatively to the large number of operations this is but a small percentage, I feel from recent experience that they represent but a portion only of those actually occurring and that a thorough and systematic inquiry would afford evidence of greater prevalence. It is the custom at the Central London Throat and Ear Hospital for all patients who are operated upon in the extern department to attend after a week's interval for examination; and in several instances the parent has reported that the child was kept at home because it had a rash which was thought to be "something catching." Subsequent investigation, however, in most cases proved its innocence of specificity. In other cases the rash was still visible on the patient, and unattended by constitutional symptoms. Of the 34 cases, three (which were in-patients) proved to be scarlet fever, while one developed diphtheria. The remainder were simple non-specific cases.

With regard to the character of the rash, the eruption generally appears on the second or third day, either papular, roseolar, or erythematous in type. It most frequently attacks the neck, the chest, and the abdomen, sometimes extending to the face and the extremities. The earliest appearance noted is the day following operation, the latest one is the sixth day. Its duration is generally two or three days but may extend to five days After reaching its maximum intensity it rapidly disappears without desquamation but is sometimes associated with intense itching. It may occur at any age; the youngest was 14 months and the oldest was 23 years.

With regard to sex, excluding the specific cases, 20 were females and 10 were males. As a rule there is but slight constitutional disturbance and the child does not appear to be any the worse. In those cases which I was able personally to investigate the temperature was only increased from 1° to 2° F. Although the incidence of so innocent a complication in our most common operation may not be unfamiliar to many of us I am not aware of any published references having been made to the subject. It is, however, a matter of some importance both to us and to the patient, since foreknowledge will help our diagnosis and prevent any undue precipitancy in forming the graver estimate of its nature. The occurrence of scarlet fever in three cases and diphtheria in one has, however, an important practical bearing insomuch that the removal of actively inflamed tonsils is advocated by many surgeons.[2] There are distinct advantages in this practice since the prominence of an inflamed tonsil affords facilities to the guillotine which disappear on subsidence of the inflammation and there do not appear to be any serious disadvantages. In the absence of any anæsthetic the operation certainly may be more painful, but it most effectually relieves the temporary angina and the removal is thorough. It may thus happen that tonsillotomy is undertaken in the early stage of recognised or unrecognised scarlet fever, diphtheria, or other specific fever, and it is maintained by many eminent specialists that not only no additional risk is involved, but that it is an expedient course to take.[3] This may be so if tonsils alone are removed, but one may reasonably doubt the expediency when a large crop of adenoids requires removal in addition, since the formation of so extensive a denuded surface is not unattended with risk.

The incidence of a rash upon any solution of continuity of tissue, operative or accidental, is well known and has been well discussed, but there are a few points associated with this particular operation which may throw some light upon its pathology. Examination of the blood during the week following the operation has with few exceptions afforded me evidence of an increase in the number of the monocular white corpuscles. This leucocytosis, which rarely lasts beyond the tenth day, may be more than coincidental, yet it is hardly surprising after so great a disturbance of lymphoid structures. The removal of tonsils and adenoids likewise affords a very large area for absorption of toxic matter. The rash may also be interpreted as one due to drug intolerance, since most of the cases were taking the usual mixture of sodium salicylate and potassium bromide. Still, whatever its pathology may be the knowledge that a rash often follows tonsillotomy and that it is not necessarily specific may be reassuring to practitioners experiencing the phenomenon for the first time.

Since the presentation of this note eight further cases have been observed and are included in the numbers given.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF CYSTINURIA IN WHICH CADAVERIN WAS FOUND IN THE URINE.

BY P. J. CAMMIDGE, M.R.C.S. ENG., L.R.C.P. LOND.,
BACTERIOLOGIST TO THE WEST RIDING COUNTY COUNCIL.

THE published cases of cystinuria, and especially those in which diamines have been found in the urine, are so few that the following is worth recording.

The patient was a girl, aged 12 years, who was seen in consultation by Dr. T. Churton of Leeds in January, 1900. In the course of a routine examination he unexpectedly found cystin crystals in the urine, and knowing that I was interested in such cases he kindly handed the specimen over to me. The urine which I received on Jan. 27th was rather pale in colour but did not smell of sulphuretted hydrogen[1] as is sometimes the case; the specific gravity was 1026 and the reaction was faintly alkaline; no albumin or sugar could be detected. Under the microscope a few six-sided plates of cystin with some triple phosphate crystals were seen. Diamines were sought for by the method of Udranszky and Baumann.[2] The whole available quantity of urine, 90 cubic centimetres, was vigorously shaken with three cubic centimetres of benzoyl chloride and 10 cubic centimetres of 10 per cent. sodium hydrate solution until the smell of the benzoyl chloride had disappeared. After standing, the precipitated diamines were separated from the phosphates, &c., which had also come down, by treatment with warm alcohol and subsequent reprecipitation with distilled water several times. Finally, a deposit of small white crystals was obtained which separated out from a perfectly clear mother liquid; this was filtered off, dried, and weighed. The dry weight was found to be 0·024 gramme. Microscopically the crystals presented the appearance of needles and narrow plates similar to those formed by benzoyl cadaverin; they were insoluble in ether but readily soluble in alcohol and strong sulphuric acid; the melting point was 129° to 130° C., characters which agree with those of benzoyl cadaverin. An attempt to prepare the picrate and double platinum salt was not successful, but this is not surprising considering the small amount of material; the yield was also too small to allow of an ultimate analysis being made. It can hardly be doubted, however, that the substance isolated from the urine was a diamine and that it consisted in all probability of pure cadaverin (pentamethylene-diamine, $C_5H_{14}N_2$).

Unfortunately, I have not been able to obtain any further specimens of the urine or a sample of the fæces, so that I am unable to say whether the excretion of cadaverin was a constant phenomenon or whether a diamine could be obtained from the solid excreta or not. The case is of some interest, however, not only because it adds one more to the 110 recorded cases of cystinuria, but also because it occurred in a female, and of the known cases only 30 are mentioned as being of that sex; further, the presence of cadaverin in a comparatively large amount is noteworthy, for, including Udranszky and Baumann's original case, this substance has been isolated from the urine in but five other cases of cystinuria, and one of these I examined with Dr. A. E. Garrod in 1899.[3]

Wakefield.

NOTE CONCERNING A SIGN OFTEN ASSOCIATED WITH EARLY PHTHISIS.

BY WALKER OVEREND, M.A., M.D. OXON.,
LATE SENIOR PHYSICIAN TO THE TOTTENHAM HOSPITAL AND RADCLIFFE FELLOW.

IN many cases of pulmonary phthisis, but more particularly in those which follow the ordinary sequence of initial deposition and consolidation within the upper lobes accompanied by dulness in the supra-clavicular and supraspinal areas, a number of venous varicosities one-third to two-thirds of an inch in length may often be observed beneath the skin in the neighbourhood of the spines of the seventh cervical and three upper dorsal vertebræ. They appear early and may become very conspicuous. At times they become apparent only after stretching the skin laterally. Local pain is occasionally felt, also slight œdema may be found over these vertebral spines. The following is an example.

The patient, aged 26 years, had suffered from cough since the beginning of April, 1901. It was probably due to influenza primarily. A note taken in the middle of May reads thus: "At the left posterior apex crepitant râles followed by slight expiratory murmur, in the lower lobe a click succeeds each inspiration; at the right posterior apex coarse râles audible, many rhonchi in lower lobe. Numerous varices visible around the spines of three upper dorsal; they occur, although sparingly, all over the left back as low as the angle of left scapula." A description of the venous ramifications of this region may serve to explain their origin. The venous network (dorsi-spinal) which lies around the dorsal spines, also furnishes branches which pass forwards between the transverse processes to join the vertebral veins in the neck and intercostal veins in the chest. The vertebral veins emerge from the transverse processes in the sixth cervical and terminate in the innominate. The veins of the upper two or three left intercostal spaces unite near the bodies of the vertebræ to form the left superior intercostal vein, which passes across the arch of the aorta to enter the left vena innominata, and the left bronchial vein opens into it. The right superior intercostal vein enters the vena azygos major. Bearing in mind these venous communications, the process by which any obstruction or deposition, be it tuberculous or not, begins to hamper the return of venous blood and leads to the formation of these spinal varices, becomes more intelligible. The obstruction may consist of enlarged and congested bronchial glands in the root of the lung, pressing upon the left superior intercostal vein during its passage across the arch of the aorta, or a thickened pleura may affect injuriously the course of the vein or any of its tributaries and lead to distal engorgement. It is important to recall the fact that the upper lobes lie tightly fixed within the three upper ribs and that they reach from the sixth cervical vertebra as far down as the third dorsal spine. The varices occur at first just within this area, between the spines and the edge of the shoulder-blade. Frequent coughing and the horizontal posture in bed, no doubt, will participate in and facilitate their production. Patients suffering from emphysema, asthma, and bronchitis, exhibit varicosities as well, but these are scattered over the chest, both front and back, and along the margins of the lower ribs, diffusely and indiscriminately. When the signs of obstruction clear the dilatations disappear, but the process requires some months. As the patient increases in weight and the fat layer beneath the skin becomes thicker, they would naturally appear less visible. In young children—five to ten years of age—who are rapidly growing or convalescing after influenza and measles, the veins are often marked and auscultation within the same region usually reveals some abnormality, tubular breathing, prolongation of inspiration, enfeebled breath-sounds, or creaking sounds. Such children are extremely vulnerable. They should be well fed and clothed, periodically weighed, and kept under observation for months.

The sign appears to me to be useful, and I have not come across it in any of the text-books and special treatises. The attention of the practitioner is at once arrested by it and the condition of the posterior apices of the upper and lower lobes determined. The presence of auscultatory signs within this dorsal area, combined with wasting and myoidema, I believe, render the diagnosis of early phthisis, even in the absence of sputum and bacilli, practically conclusive.

Clacton-on-Sea.

A CASE OF RELAPSING DIPHTHERIA.

BY H. C. BEASLEY, L.R.C.P., L.M., L.R.C.S. IREL.

REFERRING to the annotation in THE LANCET[1] on the observations of Dr. Barbier and Dr. Lobligeois regarding certain cases of "relapsing diphtheria" in the Hôpital Trousseau, Paris, the accompanying notes of a case may be of interest.

I saw the patient, a girl, aged seven years, on July 11th when she was suffering from typical diphtheria affecting the nasal chambers which were covered with membrane and from which exuded a bloody discharge, and also the tonsils and uvula which were coated with membrane; this was the third day of the disease. I injected 2000 units of anti-diphtheritic serum, this being followed by a fall in temperature. On July 12th, as the membrane was extending to the larynx, I gave a further injection of 4000 units of the serum (Parke, Davis, and Co), which brought down the temperature to normal, but the membrane continuing to extend further down the larynx and the child being in imminent danger of asphyxia, on the 13th I performed tracheotomy. The case after this proceeded so favourably that no further injection of serum seemed to me to be indicated and on the 18th I removed the tube for an hour, but the nervousness of the patient necessitated its re-introduction until the following day when it was entirely dispensed with. At this date a careful examination of the throat revealed no sign of any remaining membrane and the case progressed so favourably that on the 24th the patient had so far advanced that I did not see her again until I was sent for on the 29th, when her mother said that she had been sick the previous day and seemed very bad again. On examination of the patient the tracheotomy wound had almost entirely healed. The temperature had run up to 103° F. and was accompanied by an extremely rapid pulse, and the child looked very ill. On inspection of the throat a fresh patch of membrane of about the size of a shilling had appeared on the left tonsil. Judging from the sickness of the previous day, this was the second day of a fresh invasion and I at once injected 4000 units of the serum with a most gratifying result, the temperature and pulse rate falling to normal by the next morning. The patch of membrane had begun to get smaller, and from this date convalescence was uninterrupted.

[1] THE LANCET, August 3rd, 1901, p. 299.

Though no bacteriological examination was made I think the clinical course of the case was such as to render the diagnosis certain. The points of interest to be noted are as follows: 1. The short interval of protection afforded by the injection of 6000 units of serum, as well as by the antitoxin which we may presume to have developed in the blood of the child herself in the primary attack; this might possibly be explained by the first two injections having been given so late that the serum had only power to check, but not completely to overcome, its antagonist. 2. The value of the serum as evidenced by the remission of most of the symptoms excepting the spread of the membrane in the primary attack, without which I believe the tracheotomy would have been a failure, and its success when given at an earlier date and in a larger dose on the relapse taking place. 3 The importance of giving a large and early injection of serum.

ST. THOMAS'S HOSPITAL.

A CASE OF ACUTE INTESTINAL OBSTRUCTION RECURRING SEVEN TIMES IN FIVE YEARS AND RELIEVED SIX TIMES BY OPERATION.

(Successively under the care of Mr. G. H. MAKINS, Mr. W. H. BATTLE, Mr. C. A. BALLANCE, and Mr. EDRED M. CORNER.)

THE most striking point about strangulated umbilical hernia is the very high mortality with which it is accompanied and with this is associated a great tendency to recurrence after "radical cure." The cause of this liability to return is to be found in the condition of the abdominal wall in those adults liable to this form of hernia. It is soft, stretched, and loaded with fat, and can offer no resistance to any dilating force; while any suture applied to effect a permanent closure of the hernial opening cannot hold together the softened tissues. The following case is very remarkable for the large number of times—four in all—in which strangulation of an umbilical hernia occurred. On three subsequent occasions the bowel was obstructed owing to adhesions which had formed after the operations for the relief of the strangulated hernia. For the notes of the case we are indebted to Mr. Corner.

The patient, a woman, aged 53 years, had been married for 36 years and was the mother of 13 children, eight of whom were living. The patient was very fat and bronchitic, but otherwise there was no history of illness. Her occupation was that of a monthly nurse and she had noticed an umbilical hernia for five years. Her first admission was on August 29th, 1896 She had had strangulation for two days and was operated on by Mr. Makins. Omentum and three knuckles of small gut were found in the sac. The former was ligatured with silk and removed; the latter were returned to the abdomen. Owing to the adhesions the sac was only partially removed. A radical cure was performed, salmon gut sutures being employed; the skin was sewn with horsehair. She was discharged on Oct. 3rd, after being 34 days in hospital. The patient was now free from trouble for four months when in a violent fit of coughing the hernia appeared again.

On the second admission (Feb. 2nd, 1897) the hernia had recurred and been strangulated for one day. On admission there was a very small tender lump to the right of the scar of the former operation. Operation was performed by Mr. Makins. A knuckle of small gut was found in the sac and returned. A radical cure was performed as above. She was discharged on Feb. 26th, having been in hospital 24 days. The wound was quite sound. The hernia recurred about one year after this operation, but caused little trouble for 15 months, when it became strangulated for the third time. The interval between her admissions to the hospital was two years and three months.

On the third admission (June 2nd, 1899) there had been acute obstruction for two days, preceded by some chronic obstruction for some time. The recurrent hernia was of large size. Operation was performed by Mr. Battle. The sac was found to contain omentum and small gut. The former was ligatured with silk and removed; the latter was returned to the abdomen. Owing to the bad condition of the patient and the numerous adhesions, especially one to the left of the hernia, the sac was only partially removed and the layers were sutured hurriedly. The wound healed by first intention, but the hernia returned before the patient left the hospital. She was discharged on June 27th, after a residence of 25 days. The patient now experienced repeated attacks of pain in the hernia, which became strangulated for the fourth time, three weeks after her discharge.

On the fourth admission (July 19th, 1899) the hernia had been strangulated for seven hours. Operation was performed by Mr. Battle. The sac was found to contain transverse colon, omentum, and small gut. The omentum was ligatured and removed and the gut returned to the abdomen. The adhesions were more numerous now than they had been previously; the one to the left of the umbilicus, which had done so much to prevent the completion of the third operation, was found to consist of the omentum and transverse colon, adherent to the abdominal parietes. A radical cure was performed, silk sutures being used throughout, and the wound drained. The patient was discharged with a stitch sinus on August 12th The duration of residence was 24 days. The stitch sinus persisted and she suffered from recurring attacks of pain and occasional vomiting. Fifteen months after her discharge symptoms of strangulation again occurred.

On the fifth admission (Nov. 5th, 1901) the hernia was recurrent but small and reducible. Operation was performed by Mr. Ballance. The sac was found to contain omentum and transverse colon which was strangulated by a band of adhesions The band was divided and the gut was reduced, the omentum being ligatured and removed. A radical cure was performed with salmon gut sutures. She was discharged on Dec 15th The duration of residence was 40 days. The patient was never free from abdominal pain and discomfort and presented herself at the hospital in four months' time with symptoms of intestinal obstruction. She had from time to time had attacks of pain, vomiting, and constipation of short duration.

On the sixth admission (April 8th, 1901) there had been acute obstruction for two days and subacute for a week.

Operation was performed by Mr. Corner. An incision was made through the right rectus. The small bowel was found to be distended. A large number of adhesions were broken down. The chief obstructing agent was doubtless due to the re-formation of the large adhesion encountered by Mr. Battle at the third and fourth operations and which now consisted of transverse colon, the remains of the omentum, and small intestine and was fixed to the anterior abdominal wall. The layers were sutured with salmon gut, as were also the edges of a small recurrent hernia at the lower angle of the old scar. The old stitch sinuses (two) were scraped out, but they discharged copiously and infected the lower angle of the wound. The patient was discharged on May 8th. The duration of residence was 30 days. The patient always had pain in the abdomen and a month after her discharge a purpuric eruption broke out on her legs and a week later on the arms and abdomen. Symptoms of intestinal obstruction occurred for the seventh time, seven weeks after she left the hospital.

On the seventh admission (July 19th, 1901) there had been obstruction for 16 hours. Her abdomen was distended and most tender in the upper half. Operation was performed by Mr. Corner. An incision was made through the right rectus, but the adhesions were too dense to enable anything to be found except collapsed small gut. A further incision was made through the left rectus and the collapsed small gut was followed until the upper coil of the jejunum was found to be extremely thick and œdematous. The exact seat of the obstruction could not be ascertained owing to adhesions but was evidently very high in the small intestine; and the patient's condition forbade further operative treatment. The abdomen was closed after the transverse colon was brought out, as it had been opened in separating an adhesion. Death occurred from unrelieved obstruction in 24 hours (July 20th). Unfortunately, the body decomposed so rapidly that its diffluent condition prevented a post-mortem examination.

Remarks by Mr. Corner.—The above case is interesting as illustrating the frequent recurrences of intestinal obstruction, which was six times relieved by operation and at the seventh the obstruction could not be found. The woman was first admitted in 1896 and Mr. Makins operated; the second operation was done in 1897, also by Mr. Makins; the third and fourth operations were performed in 1899 by Mr. Battle; the fifth operation in 1900 by Mr. Ballance; and the sixth and seventh operations in 1901 by myself. On examining the literature of intestinal obstruction and strangulated hernia I was unable to find any case which could show such an extensive clinical record. The first four admissions were for strangulated umbilical hernia and the last three were for obstruction by adhesions. Strangulated hernia has the lowest mortality of all forms of intestinal obstruction, though strangulated umbilical and ventral herniæ have a higher death-rate than either the inguinal or femoral varieties. The mortality is so high in the former variety of hernia because of their large size, multiplicity of adhesions, difficulty in reducing the contents, the fat, flabby condition of the patient, and so forth. No case of femoral or inguinal hernia has been admitted to St. Thomas's Hospital in which strangulation has occurred and been relieved four times. Out of 61 operations during 1891–99 for strangulated umbilical hernia only four were performed on recurrent cases. Recurrences after "radical cure" for umbilical and ventral hernia must be fairly frequent. Out of 81 operations for "radical cure" six were recurrent cases, of which four were strangulated and two had intestinal obstruction caused by adhesions. Hence recurrent cases seem only to return when the urgent symptoms of strangulation arise.

The second variety of obstruction from which this woman suffered was caused by adhesions and is one which bears a high mortality. Three operations were performed for this; two were successful and at the third the seat of obstruction could not be reached. It was noticed in this case that the obstructing adhesions were chiefly derived from the ligatured ends left after the omentum had been removed, which subsequently gave rise to a mass consisting of the remains of the omentum, the transverse colon and small gut all becoming adherent to the anterior abdominal wall. The other adhesions did little harm except being the most likely cause of various colicky pains. This form of obstruction is commoner in umbilical and ventral than in femoral or inguinal hernia, and must especially be borne in mind in those of long standing, recurrence, or irreducibility. The hernia may even, as sometimes happens, be easily reducible. From the date of the first operation to that of her death five years elapsed.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

A CASE OF INTESTINAL OBSTRUCTION AND PERITONITIS FROM GANGRENOUS MECKEL'S DIVERTICULUM; RECOVERY.

(Under the care of Mr. George Wherry.)

It has been estimated that Meckel's diverticulum exists in about 3 per cent. of all persons. Even when it is recognised that in many of these the diverticulum is small and unimportant it is rather remarkable that more cases are not met with in which harmful symptoms arise from this developmental anomaly. Probably the explanation is to be found in the fact that "in nearly all reported instances of strangulation under a diverticulum the process has been adherent to a point other than the vicinity of the umbilicus."[1] When the diverticulum is attached to the umbilicus there is little likelihood of any strangulation occurring.

A boy, aged 14 years, was admitted into Addenbrooke's Hospital, Cambridge, on Jan. 22nd, 1901, with obstruction of the bowels. The abdomen was tympanitic and much distended; the patient vomited and there was violent pain round about the umbilicus. The onset of the attack occurred a week previously, but the more acute symptoms began three or four days before admission. No fæces or flatus had been passed for a week with the exception that Mr. R. E. Smith of Finchingfield, Essex, who was called in on the 19th, had washed away a little fæces with an enema.

An operation was at once performed under chloroform and the A.C.E. mixture. A median incision below the umbilicus let out about half a pint of turbid fluid with a foul smell; there were peritonitis and recent adhesions. The distended intestines were purplish and engorged and were tightly constricted by a band made by Meckel's diverticulum. The band was clamped near the bowel and the remainder was removed; the adherent ampullated end was black and stinking. The clamp on the stump of the diverticulum next the bowel was let free to allow the exit of some of the flatus from the distended bowel; it was then stitched with silk all around an adjacent ashy-grey patch in the intestine. There were some other ulcerated spots in the bowel which threatened to perforate, one of which was folded and stitched over with silk. Some fluid was then sponged out of the pelvis and a large rubber tube was placed in the lower part of the wound down to the bottom of the pelvis; a small superficial drain of gauze was left in the upper end of the abdominal wound.

Rapid recovery followed; the lad had some delirium during the next day or two but otherwise no anxiety arose. There was a free action of the bowels on the third day and the pelvic tube was then removed. There was a fæcal discharge from the wound later which lasted for a week or two but gradually stopped without operative interference. Mr. Smith kindly reported to Mr. Wherry that on June 21st "the boy was as well as ever" except for a slight watery discharge from the sinus, which was never fæcal.

Remarks by Mr. Wherry.—The case on admission closely resembled one of acute appendicitis with peritonitis, but there were no indications of the locality of the lesion. The diverticulum was a tube about three and a half inches long and had a firm adhesion to the mesentery at its distal clubbed end, leaving a loop across the mesentery in which the small intestines were fixed and strangulated. As the loop did not give way, but pressed like a tense tape against the congested bowel, the distal end of the diverticulum became gangrenous. The absence of any mesentery would favour the death of this extremity, as stretching proceeded in the diverticulum. No doubt if the band had given way an extravasation of fæces would have occurred with the relief of obstruction. The bowels at the operation were only partly emptied of flatus. The gentle uniform pressure of moderately distended intestine in such a condition may assist in repair of the damaged intestinal walls.

ROYAL SURREY COUNTY HOSPITAL

A CASE OF LAPAROTOMY FOR INTUSSUSCEPTION IN AN INFANT AGED FOUR MONTHS, RECOVERY

(Under the care of Mr C J SELLS)

THE early age of the patient and the apparent absence of collapse, even though the intussusception had lasted three days, are worthy of remark At the present time it is fairly generally recognised that laparotomy is the best treatment, but even as late as 1888 Mr A. E. Barker was able to find during the preceding 12 years in London only one case of successful laparotomy for intussusception [1] For the notes of the case we are indebted to Dr S Clifford Pritchard, house surgeon

A girl, aged four months was admitted into the Royal Surrey County Hospital on the morning of May 13th The history showed that for the previous two days the child had apparently been suffering from abdominal pain and the bowels had not been opened except for a little "slimy blood." On abdominal examination nothing could be found, but per rectum the prolapsed portion of the intestine was felt After a further examination under chloroform, however, this was found to have disappeared As the general condition of the patient was good it was therefore decided to wait. During the day the child seemed to be quite comfortable and passed a little flatus, the temperature which was 100° F on admission had dropped to 99° F by 6 P M On the following morning (May 14th) as the bowels had not been opened a warm water enema was given and a further rectal examination was made and the end of the intussusception was again felt. It was therefore decided to operate at once

Chloroform having been given an incision was made from the umbilicus to the pubes (about three inches in length) in the middle line The intussusception was found without much difficulty and was carefully reduced by shelling it out from the distal end without any damage to the peritoneum The parts were rather œdematous and about 18 inches of the ileum had passed in at the ileo cæcal valve The incision was then closed and the patient was returned to bed During the day and following night the temperature rose steadily until it reached 103 at 6 A M on the next morning It then dropped to 99° at 6 P M and the bowels were opened for the first time. They were again opened four hours later and the temperature had risen to 101 8° From this point the temperature again fell and the patient made an uninterrupted recovery

Reviews and Notices of Books.

Uterine Fibro myomata their Pathology Diagnosis and Treatment By E STANMORE BISHOP, F R C S Eng With 49 Illustrations London Rebman Limited 1901 Pp 324 8vo Price 15s net

ONE of the most debateable points in gynæcology at the present day is the question What are the dangers of a fibroid tumour and how is it best treated? That the treatment of such tumours is becoming more and more a matter of their removal by operation is clear from the records of the numerous cases so treated in current medical literature Whether, as Dr Champneys would have us believe the danger of death from a fibroid tumour apart from operation is only 0·000138 per cent or not is a contentious question upon which no two authorities are agreed Is it or is it not true that sarcomatous degeneration in a fibroid tumour is of common occurrence? If we search the text books for information upon this point we find the most divergent statements, and yet this is not uncommonly urged as an indication for the early removal of these tumours According to Mr Roger Williams non malignant uterine neoplasms have no special proclivity to malignant disease, on the contrary they are less prone to originate such changes than are the morphological elements of the uterus itself No doubt much of the difficulty in answering such a question lies in the ease with which a fibro sarcoma may be mistaken for a fibro-myoma, and since in many instances a certain answer can only be given by following up the after history of the patients information upon the point is always likely to be scanty and of little value In an attempt to give a comprehensive review of the whole subject Mr Bishop has written this book upon Uterine Fibro myomata From the graphic description of the numerous symptoms and ills which, the author holds accompany a fibroid tumour it is evident that he regards the life of a patient with such a tumour as one of some misery As he says if a patient escapes the numerous dangers of the presence of such a tumour, 'she leads a life which is often little more than a vegetative existence—the menopause is usually delayed and protracted, she is prematurely aged by the pain and depletion she has undergone, the prospect for such patients is gloomy in the extreme' Truly a miserable outlook. Yet there are some of us who would be inclined to regard such a description as perhaps a little more despairing than is quite warranted by the actual condition of things in many such cases. In illustration of the view which he takes the author has collected a number of cases of death resulting from fibroid tumours It is, however, a pity to have included cases where certainly a fibroid was present and the patient died but where there was no evidence forthcoming to connect the two events as for example, the case in which after death from apoplexy a calcified subperitoneal fibroid was found The author does not regard malignant degeneration of a fibro myoma as a common occurrence, and agrees with the view that sarcomata of the uterus arise *de novo* from the endothelium of the small vessels In regard to the origin of fibro-myomata he agrees with Pilliet who considers them as arising in the adventitia of the uterine capillaries, this gives origin to a zone of embryonic cells which multiply and develop into rows of concentrically placed smooth muscular fibres arranged round the vessel

In summing up the effects of medicinal treatment upon fibroid tumours the conclusion arrived at is that "prolonged medicinal treatment of fibro myomata with a view to radical cure is useless If a tumour is obviously increasing in size with or without increasing loss of blood surgical or electrical treatment is called for A chapter is devoted to the discussion of the rôle of electricity Upon the whole the author considers that the use of the constant current is admissible in certain cases where hæmorrhage is the principal symptom and where no contra indication exists The remainder—almost half of the book—is taken up with the consideration of the surgical treatment of these tumours In a general review of such treatment Mr Bishop discusses the various kinds of operations that may be performed and recommends the following four methods enucleation or myomectomy, abdominal or vaginal, abdominal hysterectomy or pan hysterectomy, vaginal hysterectomy with or without morcellement and a combination of these two latter methods He himself is in favour of vaginal hysterectomy when it is possible, a modification of Kelly's abdominal operation with removal of the cervix or pan hysterectomy by the combined method beginning from below His results before 1896 show a mortality of 25 per cent, since the abandonment of abdominal drainage the employment of the combined method, and the use of a celloidin dressing for the abdominal incision a mortality of just below 6 per cent The reasons given for the choice of the operation of combined vaginal and abdominal hysterectomy are as follows The abdominal cavity is open for as short a time as possible The separation of the bladder opening Douglas's pouch and tying the uterine arteries, are more easily carried out from the vagina. Once the uterine arteries are tied the operation is almost bloodless. When performed from above these steps have to be carried out at the end of the operation when the fingers are tired. The principle of previous vaginal freeing can be adapted to Kelly's operation and greatly facilitates the performance. In dressing wounds Mr. Bishop uses a mixture of celloidin dissolved in ether and absolute alcohol. He claims for this method that the wound can be washed without disturbing the patient, that there are no bandages to ruck up, that there are no dressings to change, that there is no fear of dust or dirt, and that there is less need of keeping the patient in one position. At the end of from 10 to 20 days the dressing peels off. For success in using this dressing several things are essential. The original wound must be aseptic, it must be dry, there must be no oozing of blood, and all air must be carefully pressed out.

---

[1] THE LANCET August 4th 1888 p 200

The last chapter, upon Final Results, is a good example of how difficult it is to get information about old patients. In answer to a number of letters addressed to different surgeons a great deal of general information has been obtained, but very little of real worth. Most of the answers given are derived from general impressions and therefore are of no scientific value. In an attempt to find out if patients after operation drift into the workhouses or infirmaries the author has applied at a large number of such institutions. In almost every case the reply is in the negative, no such cases have been met with. From this the conclusion is drawn that the operation of hysterectomy is not, as a rule, followed, as has been said, in any appreciable number of cases by such disabling conditions as fæcal fistula, ventral hernia, vaginal prolapse, or persistent pain.

The book upon the whole is a very fair summary of the present knowledge and practice with regard to fibro-myomata of the uterus. If it contains nothing very original and if the conclusions are in part tinged with the author's evident bias towards surgical interference, yet it gives a good deal of information upon a matter of great interest in a readily accessible form.

Bericht über die Achtundzwanzigste Versammlung der Ophthalmologischen Gesellschaft (Report on the Twenty-eighth Ophthalmological Congress), Heidelberg, 1900. Edited by W. HESS and TH. LEBER, with the assistance of E. VON HIPPEL and A. WAGENMANN. With 17 plates and eight Woodcuts. Wiesbaden: J. F. Bergmann. 1901. Pp. 250. Price 8*s*. (Obtainable from F. Bauermeister, foreign bookseller, Glasgow.)

THE congress to which this report refers opened under the presidency of Professor Leber, who, after giving a friendly greeting to the members, proceeded to confer the von Graefe Prize for the best essay on the Relations of the Central Nervous System and Accommodation. The two essays sent in by Professor Stephan Bernheimer and Professor Carl Hesse had been reported by the judges to be equally good, and the Graefe prize was divided between them. Professor Fuchs of Vienna was then voted to the chair by acclamation. The first paper read was by Dr. Hugo Wintersteiner of Vienna on Traumatic Cysts of the Iris. Several cases were reported. The next paper was on the Treatment of Glaucoma by Resection of the Sympathetic, by Dr. K. Grunert of Tübingen. Fifteen cases were reported, in all of which Professor Hofmeister performed the actual operation, but from other sources than his own observation Dr. Grunert was able to accumulate 47 cases, which with his own made a total of 62. The chronic acute and subacute forms of glaucoma were subjected to this treatment with the result that improvement resulted in all the cases of acute glaucoma, which were five in number. In 16 cases of chronic glaucoma 11 were improved; in 13 cases of glaucoma absolutum six were improved; in 16 of glaucoma simplex 10 improved; in eight cases of glaucoma simplex absolutum seven were improved. In four cases of hydrophthalmus the treatment failed in three but was a success in one. Dr. Grunert considered that the results were satisfactory but that more numerous data were required. Tables are appended showing the degree of improvement that was observed in each case. Dr. W. Uhthoff of Breslau read a long paper on Infectious Optic Neuritis or—to translate it more correctly in accordance with the mode in which he treats the subject—on optic neuritis as occurring in infectious diseases such as syphilis, typhus, typhoid fever, measles, and scarlet fever, and discusses the question whether the micro-organisms escape from the circulation and directly affect the nervous system or not. A paper on the Pathogenesis of Methyl-alcohol Amblyopia was read by Dr. A. Birch-Hirschfeld, who from his experiments has arrived at the conclusion that the primary seat of the action of the poison in the eye is in the ganglion cell layer of the retina and that the granule layers are subsequently affected, these conditions leading to partial degeneration of the optic disc. Professor Schmidt-Rimpler of Göttingen and Professor E. von Hippel of Heidelberg reported cases of Luxation of the Lens. The Action of Suprarenin on the Eye is the subject of a paper by Dr. K. Wessely of Heidelberg, in the course of which he shows that it prevents and removes vascular dilatation and causes dilatation of the pupil and reduces the tension of the globe.

At the sitting of the Congress on the second day Mr. H. R. Swanzy of Dublin was in the chair. Professor Fuchs of Vienna read a paper on Detachment of the Retina after Cataract Operations. Dr. F. Schiek (Halle, a.S.) described and illustrated with drawings—here reproduced in five well-executed plates which are deserving of being studied—cases of Choroiditis Exsudativa Plastica.

Professor Sattler of Leipsic laid emphasis on the advantages of the open-air treatment of all wounds of the eye and proposed that it should be applied after cataract operations. He only places a little damp pledget of wool to the lids for a short time, but takes the greatest care to secure complete asepsis before undertaking the operation. Various speakers seem to have dispensed for some time past with the long and cumbrous bandages formerly in use. Professor St. Bernheimer of Innsbrück gave the results of his experiments upon monkeys to determine the position of the sphincter centre. He states it to be a small-celled median nucleus. Dr. A. Bielschowski of Leipsic read a paper upon the so-called "divergence paralysis" and endeavoured to prove the existence of a subcortical centre for the eversion of the eyes. Other papers are on Binocular Vision, by Dr. L. Heine of Breslau, illustrated by three woodcuts; on the Limits of Acuteness of Vision, by Dr. F. Best of Giessen; and on the Visibility of Schlemm's Canal in the Living Subject.

On the third day of the Congress Professor Bernheimer of Innsbruck was in the chair and papers are stated in the report to have been read by Dr. Ed. Hummelsheim, on *Central and Peripheral Acuteness of Vision; by Professor* A. von Reuss of Vienna, on Exhausted Areas of Vision; by Dr. E. Hertel of Jena, on Changes of the Retinal Vessels in Arterio-sclerosis; on Intra-ocular Disinfection, by Dr. W. Mayweg of Hagen; on the Finer Histology of the Lacrymal Gland, especially in regard to the Presence of Fat in the Epithelial Cells; on Three Cases in which a Fragment of Iron traversed the Eyeball, by Dr. A. Wagenmann of Jena. Several of these papers were illustrated by drawings, which are reproduced in the report. The report concludes with an account of demonstrations of various cases and instruments that were exhibited before the meeting, which appears from the account here given to have been a very successful one.

Saunders's Year-Book of Medicine and Surgery. Under the general editorial charge of GEORGE M. GOULD, M.D. London and Philadelphia: W. B. Saunders and Co. 1901. Pp. 680. Price (for two vols.) 26*s*.

THE experiment made last year in issuing this work in two volumes has, we are told, proved very acceptable to subscribers and consequently this plan is continued, and the book now before us is solely concerned with "medicine." The high standard of the work exhibited in previous years is fully upheld, and an excellent summary is given of the principal contributions which have been made to medical science since the publication of the last volumes. The section of General Medicine is edited by Dr. Alfred Stengel and Dr. D. L. Edsull of Philadelphia. The abstracts on typhoid fever will be found interesting, especially the remarks on "typhoid infection without intestinal lesions" and the reports on laparotomy in cases of peritonitis occurring in the course of the fever.

The experiments of Dr. W. Goldie are also worthy of note; repeating the experiments of Flügge, he demonstrated that colonies of tubercle bacilli are obtained upon plates which are held near the mouths of patients suffering from pulmonary tuberculosis when they cough.

The section of "Pediatrics" is edited by Dr. Louis Starr and Dr. A. Hand, junior, of Philadelphia, and that on Pathology and Bacteriology by Dr. D. Riesman and Dr. A. O. J. Kelly of Philadelphia. The results of Sata's experiments in Mixed Infection in Pulmonary Tuberculosis are fully given and it is shown that the majority of advanced cases of pulmonary tuberculosis are mixed infection and that a large part of the pathological changes is the result of such secondary infection.

Dr. Archibald Church of Chicago is responsible for the section of Nervous and Mental Diseases, and Dr. L. A. Duhring and Dr. M. B. Bartzell of Philadelphia for that of Diseases of the Skin and Syphilis. Dr. R. W. Wilcox of New York and Dr. A. A. Stevens of Philadelphia report on Materia Medica, Experimental Therapeutics, and Pharmacology. Dr. G. L. Stewart of Cleveland writes on Physiology. Dr. Wyat Johnston (Montreal) edits the section of Legal Medicine; Dr. J. W. Abbott (Boston) that of Public Hygiene and Preventive Medicine; and Dr. W. Jones and Dr. Reid Hunt (Baltimore) that of Physiologic Chemistry.

Physical Diagnosis of Diseases of the Chest. By RICHARD C. CABOT, M.D., Physician to Out-patients, Massachusetts General Hospital; Assistant in Clinical Medicine, Harvard Medical School. London: Baillière, Tindall, and Cox. 1901. 142 Illustrations, pp. 326. Price 10*s.* 6*d.*

PHYSICAL signs can only be learned by actual experience; the various types of breathing, normal and abnormal, the variations in the rhythm and sounds of the heart, and the numerous phenomena connected with diseases of the chest can only be recognised after prolonged and careful study of a large number of cases. Further, physical signs must be accurately interpreted, otherwise hopeless confusion and innumerable errors will inevitably result. The bedside and the out-patient rooms are the only places where a correct idea of the physical examination of patients can be satisfactorily acquired.

Some help can, however, doubtless be obtained from a written description of physical signs, and numerous works have been published with this intent. The one now before us is one of the best on "Physical Diagnosis of Diseases of the Chest" which we have yet met with. It is of convenient size and the descriptions are couched in simple and exact terms. The point that we especially notice is that considerable stress is laid on departures from the ordinary physical signs of health which may yet not be diagnostic of disease For example, what more common mistake is made, not only by students, but by junior practitioners, than the diagnosis of "a cavity at the right apex," based on the fact that there is a small patch of bronchial breathing under the right clavicle—a phenomenon frequently occurring in perfectly healthy chests?

An interesting section is headed, "Modifications in the Second Sounds as Heard at the Base of the Heart." The majority of current text-books still repeat the mistaken statement that the aortic second sound is always louder than the pulmonic second in health, but Dr. Cabot shows that the relative intensity of the pulmonic second sound, when compared with the second sound heard in the conventional aortic area, varies considerably at different periods of life, and he shows that the relative intensity of the two sounds in the aortic and pulmonic arteries depends primarily upon the age of the individual, the pulmonic sound predominating in youth and the aortic in old age, while in the period of middle life there is relatively little discrepancy between the two, therefore pathological accentuation of the pulmonic second sound must mean a greater loudness of this sound than should be expected at the age of the patient in question and not simply a greater intensity than that of the aortic second sound. The same observation obviously applies to accentuation of the aortic second sound. These are facts of great importance in the diagnosis of cardiac disease which the student will do well to bear in mind. Dr. Cabot's work will be found a useful one both for study and for reference.

LIBRARY TABLE.

Le Diagnostic Précoce de la Tuberculose Pulmonaire. Par MM. les Drs. CH. JOURDIN et G. FISCHER, Médecins Aides-Majors. (*The Early Diagnosis of Pulmonary Tuberculosis.* By Dr. CH. JOURDIN and Dr. G. FISCHER.) Paris: A. Maloine. 1901. Pp. 148. Price 2 francs 50 centimes.—As the authors of this little book point out in their prefatory chapter, there is no doubt of the extreme importance of making an early diagnosis in cases of pulmonary tuberculosis, especially in view of the recent developments in the treatment of that disease by means of hygienic principles. They point out the difficulty of making an early diagnosis and they quote Catrin's remark: "Every one during his life, without knowing it, has been, is, or will be tuberculous, oftentimes dying from it, but more often being healed of it." The book is divided into three parts: (1) consideration of the signs furnished by external examination of the body and especially of the lungs; (2) consideration of the symptoms given by an examination of the blood and the circulatory system; and (3) consideration of the information afforded by experimental tuberculosis, agglutination tests, and the like. The authors are convinced of the great value of radioscopy and radiography, but, as they say in their final chapter, no one sign or method of diagnosis can be taken as giving indisputable proof but each sign acquires increased value according to the number of other signs and symptoms which are found to coincide with it. The book is simply and plainly written and will be found to be a valuable *résumé* of the opinions existing upon the matter with which it deals.

Rhodes's Steamship Guide for 1901–1902.—This excellent little work gives the intending passenger every conceivable information about how to get to almost any port in the world. It is a pity, we think, that our steamship lines are not more utilised for purposes of travel. To begin a journey by going to some place on board a steamer is the best way to open a holiday. The only objection is that it is a comparatively slow means of travel, and this when time is limited is a consideration. But otherwise, for the holiday maker who is going to any Mediterranean country, we should say, "Go by sea," and this book will tell him how to go. Apart from the purely guide portion of the work there are appended most interesting chapters upon naval construction and machinery. If the reader masters these he cannot do better than next to read Kipling's delightful story of "The Ship that Found Herself"

Intemperance. By Professor CAMPBELL, M.D. London: Burns and Oates. 1901. Pp. 36. Price 1*s.*—This brochure is divided into three parts—viz., Natural Remedies, Spiritual Remedies, and Auxiliary Remedies. The word "intemperance" is, we may remark, used solely in the restricted sense of alcoholic intemperance. Of the evils of drunkenness there can be no doubt, neither is there any doubt that many people drink far more than is good for them without ever getting drunk. But though Professor Campbell's remarks are for the most part sound, yet we think he spoils his case by protesting too much. His moderate drinker is, for instance, most immoderate. However, we must allow that for a certain class of character there is no medium between total abstinence and intemperance. On page 30 Professor Campbell mentions "medical practitioners who prescribe port and sherry on account of the alcohol contained in these wines. ......" Port and sherry are not, or at any rate should not be, prescribed so much on account of the alcohol which they contain but on account of the vinous ethers. If some method could be found of producing these ethers, both fixed and volatile, free from alcoholic fluids they could be prescribed apart from wines or brandies, but at present they cannot be so used.

Homoculture by Selection. By HENRY SMITH, M.D. Jena. London: Watts and Co. 1901. Pp. 38. Price 6*d*.—This pamphlet, which is mainly made up of reprints from articles contributed by the author to magazines and newspapers, contains a great number of truisms. For instance, "Social reformers must know how to cause good, and how to repress evil conduct" and "Teach the people that if they wish to have fine, healthy, and perfect children, men and women who are deformed and diseased mentally and physically must not marry nor mate ... teach them that they must help to get laws enacted to make such an act a crime and that just punishment will be the consequence." These are admirable sentiments, but Dr. Smith does not vouchsafe any information as to how he is going to obtain the realisation of such desirable ends.

When to Operate in Inflammation of the Appendix. By C. MANSELL MOULLIN, M.D. Oxon., F.R.C.S. Eng. Second edition. London: John Bale, Sons, and Danielsson, Ltd. 1901. Pp. 40. Price 2*s*. 6*d*.—These clinical lectures were originally published in, and have been reprinted from, the *Clinical Journal*. They have, however, been partly rewritten and revised for the present edition. Mr. Moullin insists upon the necessity for early operation, one "preventive in the strict sense of the term." An operation such as this must not be confused with "what is commonly called early operation upon the fourth or fifth day."

Thirty-one Twenty-four Hour Charts for Private Nurses. Arranged by FLORENCE WHITE. London: James Townsend and Son. Price 1*s*.—These charts are arranged so that the nurse, if she keeps them properly, can show to the medical practitioner a record which will enable him to see at a glance his patient's progress as regards temperature, pulse, respiration, the nourishment and stimulants taken, the medicines taken, the working of the bowels and kidneys, and the amount of sleep obtained. The charts should be found to be useful.

The Ophthalmoscope: A Manual for Students. By GUSTAVUS HARTRIDGE, F.R.C.S. Eng., Surgeon to the Royal Westminster Ophthalmic Hospital. With 65 Illustrations and four Plates. Fourth edition. London: J. & A. Churchill. 1901. Small 8vo. Pp. 153. Price 4*s*. 6*d*.—This well-known little manual has been on several occasions favourably noticed in our pages. It is clearly written and is admirably adapted for the beginner. He is not repelled by meeting on the first page which he opens an array of formulæ that he is unable to comprehend—a mathematical presentation of the subject—but Mr. Hartridge presents him with numerous and excellent diagrams which enable him to follow the path of the rays of light illuminating the fundus. The different appearances that are commonly visible of the several regions in the normal eye are well given, such as the variations in the arteries and veins both in regard to numbers, colour, and distribution, the form and colour of the optic disc, and the presence or absence of recognisable vessels in the choroid. The aspects of the principal forms of disease, such as glioma, detachment of the retina, hæmorrhages, papillitis, and others, are fully described, and as the author has drawn from nature and with large experience all the more important features are accurately reproduced. In the next edition we might suggest to Mr. Hartridge that new and better executed chromo-lithographs might replace the present ones. In the first figure of Plate 1 the disc appears to us to be too rosy in hue. Fig. 3, again, is not typical of the changes in old age. At first glance it might be considered to represent hæmorrhages in, or on, the choroid. The manual is otherwise a very good and trustworthy guide for the student.

Atlas der Krankheiten der Nase, ihrer Nebenhöhlen und des Nasenrachenraumes. Von Privat-docent Dr. P. H. GERBER, in Königsberg. Der Atlas Erscheint in 6 Leiferungen à 5-6 Tafeln nebst Text zum Preis von 6 mark für die Lieferung. Einzeln Lieferungen verden apart nicht abgegeben. (Atlas of Diseases of the Nose, the Accessory Cavities, and of the Naso-pharynx. In six parts with five or six plates with accompanying text. Price 6 marks for each part. Single parts are not sold.) Parts 2 and 3. Berlin: S. Karger, Karlstrasse, 15. 1901.—The plates in these parts are devoted to epithelial changes, atrophic rhinitis, atrophic rhinitis fœtida, hypertrophic rhinitis, papillary hypertrophies, naso-pharyngeal hypertrophies, polypi, and naso-pharyngeal polypi. The plates are well drawn, but they are not so well coloured as they might be. They show a tendency to effect the reproduction of the drawings with as few colours as possible; thus the tints of the mucosa are not quite like nature, they are all too pink in hue. The extreme value of good reproductions of drawings of diseased conditions is now recognised as being one of the most successful aids to a proper comprehension of those morbid states to which the human frame is subject, and is useful alike to the practitioner and to the teacher. To the teacher, because he can show to a class on the pictures those points to which he will direct their attention in the clinic; to the practitioner, as he can by their aid obtain much valuable information. Dr. Gerber's atlas is a useful work.

De Omnibus. By the CONDUCTOR (BARRY PAIN). 8vo. London: T. Fisher Unwin. 1901. Pp. 135. Price 2*s*.—This little book contains some desultory expressions of opinion on men, women, and manners, which are put by Mr. Barry Pain into the mouth of an omnibus conductor. There is nothing medical about the book except that it is highly laughable, and in our opinion any really humorous book may be regarded as a therapeutic agent in these days when the pressure of the day's work makes so many of us over-serious. Mr. Barry Pain's conductor is a shrewd and humorous man, and if his experiences do not encourage us to take a very high view of human nature they at any rate provoke mirth, which, we presume, is all that Mr. Barry Pain has intended to do. Angkin, the social reformer, has "grievances ag'inst ev'rythink. 'E inj'yes denarncin' and egsposin', and overthrowin' and abolishin'. If yer listen ter 'im yer'd think as most things were worm-eaten, an' the rest was 'oney-combed, and anythink left over were the thin end o' the wedge." Ike, the hard case, is described with similar apt allusiveness. The jokes against the types of Angkin and Ike may be obvious but they are none the less good; and the same may be said of most of the points which Mr. Barry Pain makes—they are not new, but he makes them gaily and fairly. "Woman the Obscure" is a capital satire on a sort of vague thoughtlessness to which too many of us are prone; "Queer Fares" are very queer; while "Them Boys" is a sound collection of the exploits of bad urchins. A bright little book.

Walks in London. By AUGUSTUS J. C. HARE. Seventh edition, revised. London: George Allen, Charing-cross-road, W.C. 1901. Pp. 780. Price 12*s.*—The publication of another edition of Mr. Hare's entertaining and instructive itinerary dealing with the many objects of interest in London is a fitting opportunity for those Londoners—and their name is Legion—who know very little of their London to take a first step in the direction of cultivating an acquaintance with the vast field of historical and antiquarian treasure which they are in the midst of. Let Mr. Hare be their guide and philosopher, and we predict that he will assuredly become their friend.

New Inventions.

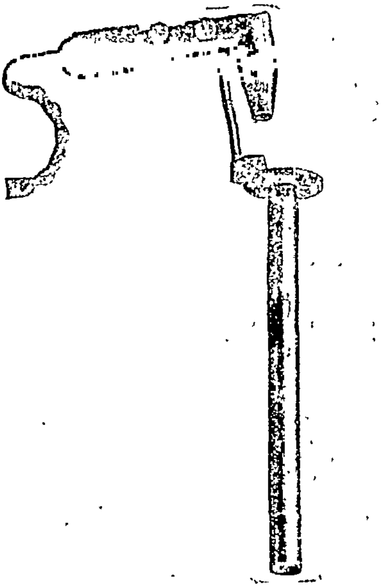
THE MODERN URETHROSCOPE.

THE introduction of electric illumination and the more recent improvements in the construction of suitable incandescent lamps have rendered the modern urethroscope so simple and efficient that from an instrument having a comparatively limited value among a few specialists it has attained a prominent position in the armamentarium of genito-urinary surgery. The difficulty of obtaining a suitable illumination of the urethroscopic field which so hampered practical examinations with the older instruments has been overcome by two separate and distinct methods, one or the other of which is now used in all forms of the modern urethroscope. In one of these the source of illumination (the electric lamp) is introduced into the urethroscopic tube close to the mucous membrane, which it directly illuminates, while in the other the source of light is altogether outside the tube, the field being illuminated by rays of light thrown down the tube, either by a reflecting mirror, prism, or lens as the case may be. The difficulty with all instruments having an internal source of illumination is that a portion of the field is obstructed by the lamp and its carrier, which, small as it is, is capable of interfering to a considerable extent when the smaller tubes are used. The light is adapted to one length of tube only and although all portions of the urethra may be observed with the long tubes, it is frequently of advantage when working in the anterior urethra to use shorter ones. With these instruments it becomes necessary to use a separate light carrier for each length of tube used. The tiny lamp is tender, easily burned out, and apt to be short-lived. All these objections are trivial, however, in comparison with the fact that the urethroscope with internal illumination is not a good working instrument. It is practically impossible to render it surgically clean. The presence of the lamp hinders the use of applicators in conveying medicated solutions directly to the mucous membrane and of swabs when bleeding and discharge are present. If this is attempted the lamp frequently becomes entangled in the cotton swabs, or becomes covered with blood or pus, rendering it, for the time being, useless and a very possible source of infection in subsequent examinations.

The illumination of the urethroscopic field by a source of light from the outside, reflected into the tube, is as old as urethroscopy itself and far antedates the experiments of Desormeaux, the first to make any serious use of this method of urethral investigation. Previously to the year 1892 all forms of the urethroscope with external illumination used the mirror in some form to direct the rays of light, and while in many of these instruments this method was fairly satisfactory it was of necessity accompanied by many drawbacks. The dazzling effect of extraneous rays of light on the eye of the operator became exceedingly unpleasant in prolonged examinations, the apparatus was usually cumbersome, and even the best of these instruments lacked necessary power.

In 1892 I devised an instrument on an entirely different principle from that of former urethroscopes, the rays of light from a small electric lamp being directed through a plano-convex lens to the bottom of the urethroscopic tube, thus attaining a better illumination and obviating most of the objections pertaining to the reflecting instruments. The instrument in its present form presents many improvements over the original device due to alterations which have suggested themselves from time to time and to advances made in electric illumination. I have also to thank Messrs. Wappler and Co. for the excellent manner in which they have put these suggestions into practical form and the success attained by them in its construction. It consists of a metal tube or cylinder an inch and a quarter in length by somewhat less than half an inch in diameter, the first half inch of which is narrowed down conically forming a funnel-[illegible]

The funnel portion unscrews from the upper tube and a plano-convex lens at this point serves to concentrate and to direct the rays of a small electric lamp placed immediately behind it. This lens may be readily removed for cleaning. The handle consists of a cylindrical piece of hard rubber about one-half inch in diameter and one and a half inches long, to the upper end of which is fixed the electric lamp, while the lower end is arranged to receive the cords leading to the battery. A small electric switch in the form of a milled wheel is placed on one side of the handle, a half turn of which makes or breaks the current. The two small screws seen on the other side of the handle serve, the upper one to clamp fast the hood, the lower to fasten the lamp in position.



Otis urethroscope showing the lamp and a portion of the urethral tube.

The lamp is of the variety known as "high efficiency," differing from the ordinary lamp in a specially prepared filament which enables it to give out a very intense light without a corresponding increase in the amount of heat. It is unusually strong and capable of standing a current of from 16 to 20 volts. It is attached to a wire running through the centre of the handle in such a manner that it may be raised or lowered and clamped in position by the lower screw. The only adjustment which may be necessary is, when changing the lamp, to see that the filament of the new lamp should come exactly in the centre of the lens. A small piece of brass with a pin-hole in it has been placed on the handle behind the lamp socket so that by holding this to the light and moving the lamp up or down until the filament is exactly across the centre of the hole the lamp may be clamped in the correct position. A strong wire connects the instrument to the urethroscopic tube by means of a simple joint. With reference to the length of the handle and the weight of the instrument, both of which have been criticised both favourably and adversely, I would say that these depend entirely on the whim of the operator, as the handle may be lengthened to any extent or entirely obviated, while by a slight alteration in material and construction the weight of less than one ounce may be reduced to a few grains.

The accompanying illustration is from a photographic reproduction exactly half the size of the original instrument. A straight line drawn along the lower edge of the urethroscopic tube through the illuminating apparatus practically demonstrates that the latter does not stand in front of the opening of the urethroscopic tube, as is commonly supposed, but is below it and consequently causes no interference with a direct view of the field or the introduction of instruments.

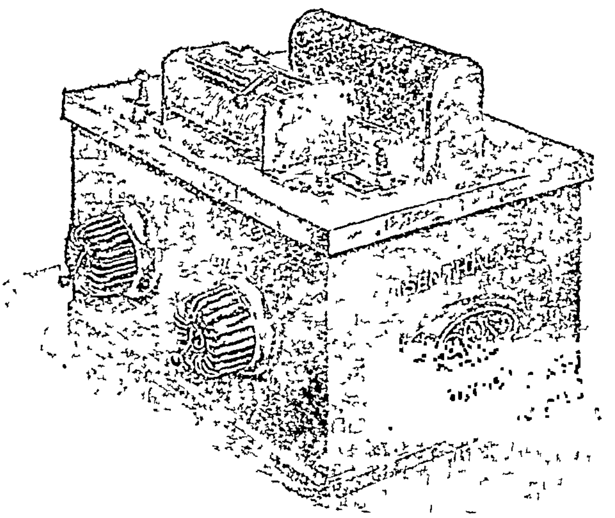
Great pains have been taken and many experiments made to perfect this instrument, with the result of obtaining an illumination of field such as is not found in any other instrument of any type. It gives the entire field of the tube used. It offers no obstruction to the use of applicators and at the same time nothing is inserted into the urethra which cannot be rendered thoroughly aseptic by boiling. It is simple in construction, strong, and inexpensive, and it fulfils all the indications of a good practical working instrument.

WILLIAM K. OTIS, M.D.,

Consulting Surgeon, City Hospital, New York; Attending Surgeon St. Mark's Hospital, Fellow, New York Academy of Medicine, and of the American Association of Genito-Urinary Surgeons, &c.

PORTABLE TRANSFORMER FOR CONTINUOUS CURRENT.

THIS apparatus has been designed essentially for the economical and convenient use of the continuous current from the main. Two types are made—the first, being 110 volt, works at pressures between 100 and 130 volts; the second type, being 220 volt, works at pressures between 200 and 230 volts. The transformer has been so desgined that neither rheostat nor lamps are required, while special heavy wires or cables are not necessary for carrying the current into the consulting-room or operating-room. Indeed, the apparatus may be directly attached to any wall, plug, or even lamp. The following instruments may be used directly from the main by means of this transformer: surgical lamps (from two volts to 30 volts), induction coils (small current), and electrolysis needles. The former instruments, taking small currents, may be used simultaneously with the cautery points or snares without affecting their work in the slightest degree The efficiency of this transformer is stated to be, when using the cautery point, about 86 5 per cent., whereas the efficiency through a rheostat would be 5 per cent. We have watched the working of this apparatus and we found the results to be very satisfactory and most conveniently attained. Its advantages for surgical work are obvious. The weight of the large type is 50 pounds and that of the ordinary type 33 pounds. These portable transformers for continuous current (one of which is shown in the accompanying illustration) are made by Messrs. Isenthal and Co., of 85, Mortimer-street, London, W.



ASYLUM REPORTS.

Cumberland and Westmoreland Asylum (Annual Report for 1900).—The average number of patients resident during the year was 648 and comprised 333 males and 315 females. During the year 192 cases were admitted, 102 of these being males and 90 females. Of these 45—viz, 28 males and 17 females—were not first admissions. Dr. W. F. Farquharson, the medical superintendent, states in his report that the admission-rate equalled that of 1895 and was higher than in any other year since the opening of the asylum. This increase, however, was due to the large number of private and out-county patients admitted. These numbered 43, of whom 16 were private, and 27 were out-county patients. "The admissions included many [illegible] character; thus there were six case[illegible] 13 cases of epilepsy, five cases of [illegible] patients over 70 years of age. I[illegible] insanity had lasted more than a year before the patient was brought to the asylum Of the 192 patients admitted 100 came here in weak health, while eight were in an extremely feeble and exhausted state, and several of these died within a few days after admission." Cases of melancholia were proportionately less numerous than usual in the admissions, cases of mania being almost thrice as numerous as cases of melancholia. 45 cases were suicidal and 15 of these had actually attempted suicide before admission. An hereditary predisposition to insanity was ascertained to exist in 27 per cent. of the admissions. More than 20 per cent. of all the cases were marked by a history of alcoholic intemperance. In many of the alcoholic cases the mental symptoms passed off within a few days after admission as soon as the alcoholic poison was eliminated from the system. "These patients invariably promise faithfully to give up intemperate habits, but few of them appear to have sufficient self-control to abstain for any length of time. Such cases cannot be detained sufficiently long in an asylum to cure them of their craving for drink; prolonged detention in an inebriate institution, could this be legally carried out, would be much more beneficial to them" Six of the patients were women with insanity after childbirth. In many instances the attack of insanity was found to be preceded by some bodily disease, influenza being a very common antecedent. The only effect of the war and popular excitement on the admissions to the asylum seems to have been an increase in alcoholic cases; "at least one such patient was admitted the inception of whose attack dated from Mafeking night." During the year 77 patients were discharged as recovered—viz., 41 males and 36 females, or 11·8 per cent of the average number resident. The deaths during the year amounted to 72—viz., 35 males and 37 females, or 11·1 per cent. as calculated on the same basis. The death-rate was the highest there had been at the asylum for 17 years In the previous year the contrary was the case, the death-rate being as low as 6·8 per cent. The mean death-rate of the two years was 8 9, which corresponds almost exactly with the average death-rate since the opening of the asylum. Of the deaths six were due to senile decay, three to epilepsy, four to pneumonia, eight to organic brain disease, 12 to cardiac disease with pulmonary complications, 13 to general paralysis, and 16 to pulmonary tuberculosis and other tuberculous diseases. A post-mortem examination was made in every case Five patients sustained accidental fractures of bones during the year and all made satisfactory recoveries. There was one outbreak of influenza which attacked a considerable number of the patients and staff in the early part of the year. Sanitary improvements in the form of soil drains and bacteria beds have been completed and are working satisfactorily. The Commissioners in Lunacy state in their report that the medical case-books are illustrated with photographs and are well kept, and that the post-mortem notes are creditable.

THE LANCET.

LONDON: SATURDAY, AUGUST 31, 1901

The Investigation of Cancer.

IT is now more than a month since the British Congress on Tuberculosis was brought to a close and we had hoped that before the end of the Parliamentary session the Government would have announced the appointment of a Commission thoroughly to investigate the question as to the identity or not of human and bovine tuberculosis. Important affairs of State cannot always be decided upon off-hand, and there are doubtless considerations other than scientific that have to be weighed before a responsible Minister can prudently advise the Sovereign to take such a step as that recommended by the Congress The President of the Local Government Board has, however, stated in the House of Commons that such an appointment is under consideration by the Cabinet; and with this assurance we may confidently leave the matter in his hands Mr LONG is a statesman who has already proved that he possesses, not only an intelligent grasp of what is essential for the preservation of health, but also the requisite determination to carry his projects into effect If and when the help of the Local Government Board is required to fight against another dread disease we hope that an administrator of his pattern will be found in authority

For there is yet another malady that, equally with tuberculosis, demands the attention of the legislature in support of the medical profession. We refer to cancer or malignant disease, which, in regard at any rate to the acuteness of the suffering entailed on its victims, is even more terrible than tuberculosis Our readers will remember that in his gracious address of welcome to the foreign delegates to the recent Congress His Majesty the KING gave emphatic expression to an opinion which, in view of recent events, every loyal Englishman will endorse with respectful sympathy "There is still," said His Majesty, "one other terrible disease which has up to now baffled the scientific and medical men of the world, and that is cancer God grant that before long you may be able to find a cure for it or to check its course I think," added the KING, "that to him who makes the discovery a statue should be erected in all the capitals of the world" We cordially endorse the view. Cancer has steadily increased in fatality, both absolutely and relatively, ever since the commencement of civil registration, the mortality attributed to it having more than doubled within the last 40 years In 1899, the latest year for which returns have been published, the deaths from cancer in England and Wales exceeded 26,000 in number Without going deeply into statistics we may remark that although in early life cancer claims fewer victims than does pulmonary tuberculosis, nevertheless, at all ages beyond middle life it is considerably more fatal than the latter disease, especially amongst women. In the valuable series of reports prepared at Somerset House we are kept informed year by year of the rapidly increasing death toll levied by cancer on different sections of the community so far as this can be gleaned from the national registers of death But it appears to us that in order to arrive at a sound judgment respecting the *essential nature* of cancer very much is required beyond a merely statistical analysis of the mortality to which it gives rise The etiology of malignant disease in its varied forms will never be fully understood save after diligent and rightly directed study of cases in the hospital and rigid examination of specimens in the laboratory This is the method which has revealed the true nature of tubercle and certain other scourges of humanity, and has shown them to be preventable In these later days the tendency amongst persons afflicted with cancer is to resort in gradually increasing numbers to the hospitals of our great towns where good nursing and the best medical advice are at their disposal And inasmuch as at these institutions careful necropsies are made in fatal cases by competent pathologists there is little doubt that even now there exists in the registers of these hospitals a vast amount of information of precisely the kind required which might readily be made available for detailed examination if only a suitable authority were commissioned for the work *Why should there be any longer delay?*

A doubt has often been expressed whether a Royal Commission is better adapted than other known methods for the investigation of a scientific subject like an elaborate inquiry into the etiology and prevention of malignant disease in all its protean forms For our part we think nothing but immense good could come from the appointment of such a Commission No immediate discoveries might follow its work, but there would be sifting and codifying of evidence that could not fail to be enormously helpful to future investigation, while valuable suggestions might come from unexpected quarters In the distinguished chief of his own medical department the President of the Local Government Board possesses a counsellor of rare ability and we are sure that any project of the kind which received Mr W H POWER's approval would secure also the confidence and willing coöperation of the medical profession

Suggestive Discussions at the British Medical Association.

THE papers and discussions which were respectively read and held at the recent meeting of the British Medical Association at Cheltenham were fully up to the high standard usually attained at the annual assemblies of the Association. Some of the discussions were essentially practical, whilst others had a more theoretical aspect We refer to two which seem to us likely to be of particular importance as foreshadowing future developments of knowledge

In a leading article in THE LANCET of Feb 2nd of this year we alluded to the doubt which had been expressed by some observers as to the power of alcohol to produce peripheral neuritis, and during the discussion at Cheltenham opened by Dr E. S REYNOLDS some of the speakers expressed the same opinion, but the majority suggested that the causation was a mixed one. Dr DIXON MANN thought that alcohol acted by interfering with the molecular changes in the nerve-cells, so rendering them liable to be affected by the arsenic, and Dr A. P. LUFF supported this view. Dr. T. N. KELYNACK produced statistics which seemed to indicate that much of the so-called alcoholic paralysis met with in Manchester and district during recent years had really arisen from the use of arsenicated beer, but he considered that the effects of arsenic had been modified by the method of its administration in beer and urged that they had been accentuated by the action of the arsenic. Dr. NATHAN RAW also believed that all the cases in the epidemic referred to were caused by arsenic and that alcohol intensified its action; he also pointed out that the effects of arsenical neuritis were recovered from more rapidly and completely than were those of the alcoholic form. Dr. F. M POPE hesitated to accept the theory that alcohol alone could produce the disease, and Sir WILLIAM GAIRDNER argued that in view of the large amount of alcohol consumed and the rarity of neuritis in previous years alcohol could not be the cause of the condition. Professor W. OSLER, on the other hand, said that although alcoholic neuritis is rare in America, yet it did occur, and the symptoms observed were identical with those which had been described in arsenical cases, with the exception of those relating to the skin and the vaso-motor functions, and he fully believed that alcohol was the cause of the disease in the cases which he had seen. With such differences of opinion emanating from well-known authorities it is evident that at present no definite conclusion can be arrived at. As Dr. REYNOLDS pointed out there are three possibilities: first, that the symptoms were caused by alcohol and arsenic acting together—e.g., that the arsenic caused the effect upon the skin and that the alcohol caused the neuritis; secondly, that all previous cases were really due to arsenic and not to alcohol; and, thirdly, that alcohol and arsenic were both separately able to produce all the symptoms of the disease, but that their action was intensified when they were both acting together. At present we should feel disposed to favour the third proposition. All modern text-books describe peripheral neuritis arising from the consumption of alcohol and of arsenic, and without stronger evidence than has already been brought forward we should not feel justified in entirely eliminating alcohol as a cause of that disease.

Another discussion of considerable interest was that opened by Mr. A. G. R. FOULERTON on the Pathology of Pneumococcic Infection. Considered solely from the point of view of a pathogenic organism the pneumococcus is in some respects disappointing, as it is frequently found in healthy individuals without giving rise to any morbid symptoms; but this only serves to accentuate the fact that a disease caused by a pathogenic microbe requires a second causal agent in the shape of a suitable pabulum upon which the micro-organism can grow and so produce its pathological effects. There is another parasite which exists under very similar circumstances—namely, the bacillus coli communis. This organism, although a universal and, according to BIENSTOCK, a useful parasite of the intestinal tract, becomes, nevertheless, like the pneumococcus, actively pathogenic when it finds the opportunity of penetrating below the mucous membrane. Mr. FOULERTON adopted a practical method of treating his subject, laying stress on three points—(1) the general results of blood infection and those of the toxæmia produced by the absorption and circulation of toxins formed in the local foci of infection in the tissues or produced by cocci which had infected the circulating blood itself; (2) the direct action of the parasite in the various tissues in which it became located in the course of an infection; and (3) what might be termed the secondary results of the infection—that is to say, those results due not to any direct action of the infecting organism but arising from the new morbid conditions brought about by the infection. Clinical experience shows that in the case of pneumococcic infection these secondary effects are often of the greatest importance and not infrequently active treatment is mainly directed to combating them. Thus there are the effects on the right heart of the obstruction to the flow of blood through the infected area of the lung, the serious results of sudden diminution of the surface available for the oxygenation of the blood, and the effects of interference with cerebral function in cases of meningitis. Mr. FOULERTON further pointed out that with regard to the exact nature of the toxic substances produced in the course of a pneumococcic infection very little is known and it is uncertain whether such are actually secreted by the cocci themselves or whether they are formed from the infected tissues by the action of the cocci. He then referred to the work of Professor KLEMPERER who had isolated a toxic albumose, pneumotoxin, from broth cultures of the coccus, and also mentioned that Dr. A. G. AULD had isolated an albumose from the infected tissues. Dr. J. W. WASHBOURN, the president of the section, who took part in the discussion, expressed himself as not satisfied as to the isolation of toxic substances from cultures of the pneumococcus, he himself having failed to isolate any toxic albumin.

Another point to which Mr. FOULERTON drew attention was in respect to the alterations in the tissues brought about by the action of the pneumococcus. Various changes had been described in the cardiac and voluntary muscles, and he also said that there was a certain amount of evidence that changes in the motor ganglion cells might result. Dr. CAMPBELL THOMSON and himself, when investigating the action of various bacterial toxins on the motor-cells of the cerebral cortex, found some indications of structural alteration in these cells in pneumococcic infection. Although the knowledge yet attained in these matters is evidently rudimentary, yet such discussions as the above serve admirably to take stock of the amount of work which has already been accomplished—an opportunity is given for various investigators to compare their results and to give an impetus to others to continue their researches. When the action of toxins has been thoroughly investigated the path will be more open for a study of natural and artificial immunity, and for the discovery of measures which will be effectual in the destruction of the toxins and in combating their deleterious action.

◆

The Pathology and Treatment of Fibroid Tumours of the Uterus.

THERE is no subject which is of greater interest to the obstetrician or the gynæcologist than the pathology and treatment of fibroid tumours of the uterus and none in which, by a gradual evolution, there has been a more marked change of opinion and of practice. While in former times fibroid tumours, the most common uterine growths met with among women, were looked upon as by no means dangerous and as rarely needing surgical treatment, now the great advances in abdominal surgery, the more careful examination (post-operative and post-mortem) of these tumours, and the present more accurate clinical observation, have shown that they are by no means so simple as was formerly thought and that women, the subjects of them, demand the most careful watching. When a fibroid tumour is discovered, if it is doing no harm clearly it should be left alone; but it is as unscientific to say that no fibroids should be interfered with as that all should be removed. Putting aside such cases as fibroids taking the form of polypi, which, of course, should be removed, what are the indications for surgical interference in fibroids? We think all will agree that in the presence of (1) severe hæmorrhage, (2) pressure symptoms, and (3) signs of degeneration in the tumour operative treatment is needed. The question of the occurrence of degeneration in fibroid tumours is of the greatest import, and we believe the trend of opinion is that it is more common than was formerly suspected, and this view is supported by the results of the more careful examination of these tumours which is now being every day made by competent pathologists The forms of degeneration are numerous, such as sloughing, myxomatous or cystic degeneration, calcareous infiltration, and vascular changes It is common with some to speak of malignant or sarcomatous degeneration in fibroids, but we think that any malignant condition noticed in such growths should be regarded as of independent origin; however, we must not forget that PROCHOWNICK[1] has shown that degeneration may occur in a fibroid which on microscopic examination is innocent, and yet in its effect on the patient the degeneration may really be almost of a malignant nature. We owe much to the observations of PROCHOWNICK, which he brought before the Hamburg Medical Society in March, 1901, as well as to the paper read on July 11th at the British Gynæcological Society by Dr. CHARLES NOBLE[2] of Philadelphia, in which he gave details of 218 cases of uterine fibroids upon which he had operated. While one thing is established clearly—viz., that degeneration taking place *after* the menopause is much more serious in its import for the patient—we are quite ignorant as to what cases will or will not undergo degeneration The clinical symptoms which indicate the occurrence of degeneration in a fibroid are: (1) sudden enlargement of the tumour; (2) abdominal pains due to increased tension, or it may be to peritoneal inflammation; (3) increased menstrual loss; (4) reflex (cardiac and renal) irritation; and (5) the presence of ascites. Another curious fact which all gynæcologists must have observed is the frequent presence of adnexal or broad ligament complications with fibroids Finally, we must draw attention to conditions of the general system of serious import often present in patients with fibroids due to the continued hæmorrhage and pressure effects, such as anæmia, fatty heart, or signs of interference with the bladder or kidney

Apart from these accepted indications for operation, may not the mere size of a fibroid call for its removal (1) if it constitutes a deformity; (2) if it prevents a woman (a governess or servant) from obtaining a situation; and (3) if by its size and shape it exposes a woman to adverse criticism? One thing is clear, we can lay down no rules applicable to all cases of fibroids, each one must be judged on its own merits; but we must never forget that fibroids, owing to their tendency to degeneration, are at all times "tricky" tumours, and especially is this true after the menopause. Indeed, the old belief that they tend to disappear after the cessation of menstruation is one which in the light of modern observation must be received *cum grano salis*. They do disappear in some, but by no means in all, cases after the menopause. As to treatment, the electrical method and the plan of removing both ovaries (with the idea of starving the tumour) are procedures of the past. Morcellement and myomectomy suit some cases, but in the main retroperitoneal hysterectomy is the method which for the present holds the field In its technique (the Trendelenburg position is an enormous gain) the principal points are to make the peritoneal flaps as small as possible (so as to leave no space where fluid may decompose), just sufficient to cover the stump (which should not be sutured). The stump and all the ligatures should be covered with peritoneum and the vessels should be tied on ordinary surgical principles; that is, rather than ligature them *en masse* with some of the broad ligament, it is wiser to amputate the uterus and to tie the vessels as they spout. A pedicle needle tends to wound the veins. There are two drugs which are useful accessories in the surgical treatment of fibroids, strychnine and spartein. Dr. W. DUNCAN,[3] to avert shock and heart failure, gives liquor strychninæ in three-minim doses thrice daily for a week before and a week after hysterectomy, while Mr. ALBAN DORAN[4] says that he has found spartein useful, especially in the cases of middle-aged women with unhealthy kidneys. Early feeding of the patients after hysterectomy is now found to be more advantageous than the long starvation which was Mr. LAWSON TAIT's plan; and another point in these cases to be most carefully looked after is distension of the bowel, for which early and thorough purgation, combined, if necessary, with turpentine enemata, is indicated.

The Lunacy Problem and Official Statistics.

THE total number of lunatics England and Wales under the official cognisance of the Commissioners in Lunacy on Jan 12th, 1901, was 107,944, being an increase of 1333 over the corresponding number for Jan. 1st, 1900 This increase compares with an increase of 1525 in 1899 and one of 3114 in 1898. It would thus appear that there has been "a diminishing rate of increase of lunatics in the last two years," on the basis of census returns of all lunatics on Jan. 1st of the three years 1889 to 1901. This conclusion is likely to be misleading, for the choice of any date assumes that the number of the insane under official cognisance on a given date is fairly regular even in its variations This, however, is not the case, for in one year there may be a host of cases above the average on a given date, in January for instance, and next year there may not be a fourth of the excess. The only fair estimate of the increase or diminution of insanity available from the Commissioners' returns is the daily average number of lunatics resident in all institutions for each year. In Table IV. of the annual report of the Commissioners in Lunacy the daily average number resident "in asylums, registered hospitals, &c," but exclusive of lunatics in workhouses and "out-door" pauper lunatics, in each of the years 1891 to 1900 inclusive is recorded, the figures being 75,200 for 1896, 77,645 for 1897, 80,408 for 1898, 82,666 for 1899, and 83,954 for 1900 In idiot establishments the average numbers resident during the four years 1897 to 1900 have been almost entirely unchanged, so that the increase solely affects county and borough asylums and other institutions exclusive of idiot establishments The total numbers of patients admitted yearly (exclusive of transfers) to all institutions except idiot establishments are given in Table III and are as follows There were 18,632 admissions in 1896, 18,848 in 1897, 19,314 in 1898, 19,289 in 1899, and 19,837 in 1900 Limiting ourselves to "first admissions" the only figures available at present refer to the past three years and are as follows. In 1898 the first admissions amounted to 15,514, in 1899 to 15,752, and in 1900 to 16,192 It is thus clearly established on the basis of Tables III and IV —viz, average numbers resident, total admissions, and "first" admissions—that the increase of lunacy is real and not apparent, and, moreover, that this rate of increase is slightly greater than the rate of increase of the general population.

---

[1] Münchener Medicinische Wochenschrift, 1901, No. 19.
[2] THE LANCET, July 27th, 1900, p. 210.
[3] THE LANCET, August 17th, 1901, p. 467.
[4] THE LANCET, August 17th, 1901, p. 467.

A survey of the returns published regarding the recoveries and deaths during each year will serve to emphasise the same conclusion The general recovery-rate in 1896 was 9 78 per cent of the average number resident in all institutions, and the death-rate was slightly lower—viz, 9 05 per cent—as calculated on the same basis. During the quinquennium 1896 to 1900 the recovery-rate has slowly fallen and the death-rate has slowly risen, as will be seen from the following table taken from Table VIII. —

	Recovery rate on average number resident.	Death rate on average number resident
1896	9 78 per cent	9·05 per cent.
1897	9 53 ,,	9·43 ,,
1898	9·06 ,,	9·45 ,,
1899	9 37 ,,	9·87 ,,
1900	9 27 ,,	10·14 ,,

This fall of the recovery-rate affects both sexes, and a tabulation of the returns for the period 1873 to 1900 into quinquennial groups brings out the facts more plainly :—

Quinquennial periods	Proportion of recoveries to daily average numbers resident	
	Males.	Females.
377	11 03 per cent	11·99 per cent.
82	10 63 ,,	11·41 ,,
7	9 70 ,,	10 61 ,,
	9 78 ,,	10 52 ,,
	9 71 ,,	10 22 ,,
	9 06 ,,	9 37 ,,

* Three years.

n Lunacy advert to these figures as decline" in the recovery-rate and no doubt, from the great id incurable cases." Some support is lent to this view by the fact that a considerable proportion of patients are senile cases. Thus the number of patients in the institutions at the end of December, 1899, who were aged 65 years and upwards was 10,092, or 12 18 per cent. of the total patients—a slightly lower proportion than at the end of December, 1898, which was 12·37 per cent. An increasing and continued influx into pauper asylums of non-recoverable cases other than senile cases is probably the main factor in the lowering of the recovery-rate In this connexion it is interesting to note that of the total admissions in the years 1895 to 1899 inclusive 7·3 per cent. were cases of general paralysis and 7 7 per cent. were due to epilepsy.

The deaths during the year amounted to 8356 and the causes of deaths are given in Table XIV. Of the deaths 1344 (1031 males and 313 females) were due to general paralysis of the insane, 433 to epilepsy, 1185 to pulmonary tuberculosis and 104 to other forms of tuberculosis, 689 to pneumonia, 773 to various forms of cardiac disease, 752 to senile decay, 179 to colitis, and the rest to other causes. Amongst the latter, however, are included such vague terms as "congestion of the brain," "toxic paralysis," "disease of spleen," and "atrophy," which convey no definite information.

The Commissioners draw special attention to the need for classification of patients and for the provision of cheaper institutions for the chronic and incurable classes of patients The ordinary modern county and borough asylum, being essentially and primarily a hospital for the treatment of disease, is necessarily costly in construction and equipment What is needed is the differentiation of asylum buildings at the present day in such a manner that there shall be mental hospitals for the recoverable and the acutely insane, and simple, inexpensive buildings for the accommodation and care of chronic and incurable lunatics. In this way it would be possible to limit excessive expenditure and yet to afford due provision to both classes of patients without imposing an undue burden upon the public With this view, and to secure these ends, the Commissioners had already addressed a circular to the county councils and other authorities concerned, in which the latter were advised that the Commissioners would regard it as their duty "to advise the Secretary of State to refuse his approval of all [asylum] plans in which there is an obvious departure from this principle"

The study of the present report of the Commissioners in Lunacy leaves on the whole a feeling of uneasiness. With a slow but steady increase of the average lunacy population year by year, a decreasing recovery-rate, an increasing death-rate, and a continued and increasing influx of incurable and refractory cases of mental disease into our public asylums, the conviction is slowly being strengthened that with all our boasted scientific and medical progress in the past decades the cure of the insanities as a whole has fallen behind expectations, and that the only hope of progress in the future lies in devoting more attention and study to the prevention of insanity on the lines advocated by many of our leading alienists and referred to in these columns a year ago.[1]

Annotations.

"Ne quid nimis."

THE ERADICATION OF RABIES FROM ENGLAND.

"DURING the whole of 1900 no case of rabies was confirmed in England or Scotland and it may be stated with some confidence that in these two countries the disease which has been present there for so many centuries, has been entirely eradicated." These are the opening words of the paragraph on rabies in the recently issued "Annual Report of Proceedings Under the Diseases of Animals Acts" for 1900. This report is the official one of the Veterinary and Animals' Department of the Board of Agriculture and is the combined work of the chief veterinary officer (Mr. A. C. Cope) and the assistant secretary of the Animals' Division (Major Tennant, C.B.). As a result of the action of the Board during the last four years rabies has been confined to the counties of Brecon, Carmarthen, and Glamorgan in Wales in 1900, in which counties six cases in dogs, four in cattle, and one in a horse were confirmed by the Board's veterinary officers. In addition, 15 dogs which had been exposed to infection were slaughtered in Carmarthenshire. In Lancashire, where rabies used to be very prevalent, 15 inoculative tests were carried out at the University of Liverpool during the year, but all with negative results. In fact, with the exception of one case in an imported dog, which occurred in the North Riding in 1899, the whole of Lancashire and the three Ridings of Yorkshire have been free from rabies for upwards of two years. In the metropolis and surrounding counties no case has been detected since July, 1898. In numerous instances dogs have been killed but in no instance has the existence of rabies been demonstrated by inoculation. The inoculation test was applied during the year in seven instances at the Brown Institution and in nine at the Royal Veterinary College. All gave negative results. One inoculation was also carried out with portions of the brain of a bullock which had been bitten by one of the rabid dogs discovered in Wales, and the result confirmed the opinion which had already been expressed by the officers of the Board—viz., that the dog which had bitten the bullock was affected with rabies. The only really dangerous centre of the disease in Great Britain at the end of 1900 was South Wales, a part of the country where rabies has often been more or less prevalent, and a district which, by reason of its mountainous nature, renders it extremely difficult to enforce a muzzling regulation. With such results as the above the Board of Agriculture and the able Minister, Mr. Walter Long (who enforced the muzzling order in the face of so much opposition), have every reason to congratulate themselves. When we read that 'France still reports from 2000 to 3000 cases in a year, that in Italy nearly five times as many cases were declared in 1900 as in 1899, that in Belgium the disease is on the increase, and that in India and America rabies is still prevalent,' we in England must feel that we owe a deep debt of gratitude to Mr. Long and to his veterinary and administrative advisers. For the first time during 51 years not a single human being died in the year 1899 from hydrophobia in England and Wales, and the returns for 1900 show a similar result. The good work is the more readily realised when we read that in 1877 no fewer than 79 persons were registered as having died from this terrible disease. Much abuse has been poured upon Mr. Long and his advisers during the past five years, but, fortunately, they have stood firmly by their convictions, and even their most fanatical persecutor must now own that the end has more than justified the means. No other European country can show such a clean sheet with regard to the rabies question, and it now only remains to watch the ports to see that the disease is not re-introduced. No relaxation must be permitted in the quarantine regulations, and it is to be hoped that when the next report is issued there will be as clean a bill of health for Ireland and Wales as for England and Scotland.

GONORRHŒAL PERITONITIS IN LITTLE GIRLS.

AT the meeting of the Société Médicale des Hôpitaux of Paris on May 24th Dr. M. J. Comby and Dr. Gadaud called attention to a complication of the vulvo-vaginitis of children—gonococcic peritonitis. In consequence of the rarity of this complication its connexion with the vulvo-vaginitis, which may be trivial or overlooked, may not be noticed and the peritonitis may be regarded as the result of perforation or appendicitis. Dr. Comby and Dr. Gadaud related three cases in which the latter condition was regarded as the cause of the peritonitis. Case 1. A girl, aged 12 years, was admitted to hospital on Sept. 25th, 1900, for typhoid fever. The attack was severe and lasted for 36 days. The temperature became normal on Oct. 13th and convalescence began. On Nov. 14th pyrexia (102·8° F.), headache, and vomiting suddenly appeared, and the child complained of acute abdominal pain. On the 15th the pain was still violent and the abdomen was exquisitely tender and tympanitic. She lay immobile in the dorsal decubitus position with the thighs flexed on the abdomen. The face was pale and anxious, the lips were blue, and the extremities were cold and cyanosed. The temperature was 100·4° and the pulse was 145. There were vomiting and diarrhœa. No special signs were found at McBurney's point and rectal examination was negative. General peritonitis was diagnosed. The period—the thirty-second day of convalescence—seemed too late for typhoid perforation. A symptom previously unnoticed then attracted attention: there was a greenish vulvo-vaginal discharge. The vulva was red and the labia majora were covered with dried pus. The gonococcus could not be found. The child's condition was so serious that laparotomy was proposed, but recovery took place under medical treatment. Case 2. A girl, aged six and a half years, was admitted to hospital on Nov. 27th, 1900, suffering from pains in the abdomen which began eight days previously with vomiting. There were prostration, algidity, cyanosed extremities, and pale and pinched face. The pulse was 140 and small, and the temperature was 99·5° F. There was an abundant vaginal discharge which had existed for some time and lately had become recrudescent. The gonococcus could not be found. Ice applications to the abdomen, hypodermic injections of morphine, and saline injections were prescribed. In five days recovery was assured. On Jan. 7th, 1901, a relapse occurred. After seven days recovery began. Case 3. A girl, aged six and a half years, entered hospital on Oct. 16th, 1900, with purulent pleurisy secondary to pneumonia. She had recovered by Nov. 15th without other operation than exploratory puncture. On Jan. 8th, 1901, there were acute abdominal pain and diarrhœa. The thighs were flexed on the abdomen which was tense and tympanitic. The temperature was 102·3° F. and the pulse was 180. On the 10th the general state was much graver, the eyes were sunken, the nose was pinched, and the lips were blue. Perforative appendicitis and pneumococcic peritonitis suggested themselves, but a greenish purulent vaginal discharge which contained gonococci was observed. The patient appeared to have contracted the vulvo-vaginitis in hospital, perhaps from a thermometer or a basin. Recovery was complete on Jan. 16th. These three cases were observed almost at the same time in the Hôpital des Enfants Malades, Paris. In the first two cases the vulvo-vaginitis was old or unrecognised and the gonococcus was not found, in the third case the vulvo-vaginitis was recent and the gonococcus was found.

This form of peritonitis is not very rare; a number of cases have been published of which some were fatal. In a case described by Huber of New York appendicitis was diagnosed and the abdomen was opened. At the necropsy salpingitis and a healthy appendix were found. In a case under the care of Baginsky there were salpingo-ovaritis and pus in the pelvis which contained gonococci. The peritonitis of vulvo-vaginitis, in spite of the acuteness and severity of the symptoms, generally terminates quickly in recovery. Hence intervention should not be precipitate. In this form of peritonitis vulvo-vaginitis is generally the last thing to be thought of and the appendix is incriminated. When a little girl suffers from peritonitis the external genitals should always be examined. If vulvo-vaginitis is present the possibility of gonococcic peritonitis should be borne in mind. Its diagnosis indicates abstention from operation.

"THE NEW POOR-LAW INFIRMARY AT HALIFAX."[1]

At the fortnightly meeting of the Halifax Board of Guardians, held on August 21st, Father Russell, who had given notice that he would move, "That Dr. Dolan be appointed medical officer of the Halifax Union Poor-law Hospital, Salterhebble, at a salary of 100 guineas per annum, this sum not to be included in the superannuation allowance," modified his notice of motion and simply proposed that Dr. T. M. Dolan should be appointed at a salary of 100 guineas per annum. Mr. J. W. Tillotson, the chairman, said that Dr. Dolan had written to the Local Government Board applying to be superannuated then and there, but that the Board had replied that such a course was impossible. Father Russell's motion was rejected by 20 votes to three. So there the matter stands at present. Dr. Dolan keeps his post as medical officer of the workhouse and the board of guardians are trying to get three medical officers for the new infirmary. The senior medical officer is to be the responsible officer of the three and is to have a salary of £105 per annum, while he is to take the appointment subject to the duties being hereafter defined. We await further developments with interest.

THE SYMPTOMS OF POISONING BY FUSEL OIL.

Dr. Thomas B. Futcher of Johns Hopkins University records in the *New York Medical Journal* of August 3rd two cases from the clinic of Professor Osler of the somewhat rare condition of poisoning by "fusel oil," an ingredient of crude spirits. The cases recorded in medical literature are very few. Dr. W. M. Ord reported a case at St. Thomas's Hospital in 1889,[2] and Dr. J. Swain[3] recorded a fatal case at the Bristol Royal Infirmary in 1891. Fusel oil is the common name for primary amyl alcohol ($C_5H_{11}OH$) mixed with primary and secondary propyl alcohols. In England it goes by the name of "faints," and can be obtained gratis from some distilleries. Fusel oil is popularly used as an external application for rheumatism. It is obtained from fermented grain or potatoes by continuing the process of distillation after the ordinary "spirit" has ceased to distil over, and forms an oily liquid with a burning acrid taste and an odour said to resemble jargonelle pear. It has intoxicating and poisonous properties superior to those of ordinary spirits, and is said to be known in some of the northern counties of Europe to the consumers of corn brandy who frequently ask to be served with a "glass of good fusel." The two cases recorded by Dr. Futcher are as follows:—Case 1 was that of a woman, aged 28 years, who was admitted to the Johns Hopkins Hospital at about midnight, complaining of general weakness. It was found that in company with a male (Case 2 *infra*) she had been drinking out of a six-ounce bottle of fusel oil during a debauch and was lying unconscious on the floor. At 9 A.M. next morning she had a headache, coated tongue, and a bad taste in the mouth, and suffered from general weakness. Her forehead was red from rubbing it, as she stated, with fusel oil a day earlier. There was a slight bronchitis. The pupils were normal in reaction and an estimation of the blood showed 4,500,000 of red corpuscles and 7000 leucocytes per cubic centimetre. The urine was of a pale yellow colour and slightly hazy, with a white precipitate, and exhaled "a peculiar odour resembling violets." There was a faint trace of albumin, and on testing with Fehling's solution sugar was found to be present. Tests with phenylhydrazine and with yeast confirmed the presence of sugar, but the polariscope showed that it was not glucose (dextrose) as the solution was lævo-rotatory. Next day the urine was free from sugar, but a trace of albumin persisted for a day or two longer. She was discharged as recovered after four days. Case 2 was that of a man, aged 28 years, who was admitted into the hospital at the same time and under the same conditions as the above patient. His temperature was 100° F., the pulse was 120, and the respirations were 48 per minute. The right arm showed impairment of sensation and the right leg showed loss of power and an excessive knee-jerk. He gradually improved in hospital, though the muscular and sensory impairment persisted for four or five days. He was discharged on the sixth day. His urine had a dark brown "smoky" appearance with a "peculiar aromatic fruity odour." It gave the same chemical reaction for sugar as did the urine in the previous case, but was inactive to polarised light. Methæmoglobin was also present in the urine with a few broken-down red corpuscles. The sugar disappeared from the urine during the second day. The presence of sugar in both these cases was a peculiar and very rare feature.

VERMINOUS HOLLOWAY GAOL.

Complaints have recently been heard from unfortunate prisoners of the filthily verminous condition of Holloway Gaol, and the forcible remarks of Alderman Sir Joseph Renals, sitting at the Mansion House Police-court, led recently to an interview between his worship and the chairman of the visiting justices of the prison. Correspondence on the subject is also said to be proceeding between the visiting justices and the Prison Commissioners. The case which particularly called attention to what constitutes a serious scandal was that of a man remanded under a charge of obtaining goods by false pretences—that is to say, of a man neither convicted of a crime nor temporarily imprisoned in a cell constantly used by many different occupants brought in at random from the streets, as is the case with cells at London police-stations. The condition of this prisoner's face was such that Sir Joseph Renals, on his attention being called to it, remarked that he had noticed it and had thought that the prisoner must have had small-pox. Whatever remedies may be suggested and whatever means of prevention may be adopted in future it will hardly, we hope, be suggested that the state of things apparently existing in one of our principal metropolitan prisons—an establishment which ought to serve as a model for the imitation of similar institutions in this country—is either inevitable or anything short of disgraceful. Many prisoners no doubt come into Holloway Gaol with vermin upon them. We are not aware of the precise arrangements as to the cleansing of the persons and clothing of the unconvicted, but it is, we believe, possible to deal to some extent with those who are obviously in need of purification, while even if we grant that insect life must often be found where dirty people have been, we are still a long way from admitting that insects need be left to breed and to multiply undisturbed in a place where there is almost unlimited labour at the disposal of the gaol governor. Sir Joseph Renals spoke of the plank beds at Holloway as harbouring vermin. No doubt they do, but insects of the kind referred to do not burrow into solid wood or stone; they take shelter in chinks and crevices, which need not be there for their benefit, and multiply their species if left to do so undisturbed by soap-and-water and other agents obnoxious to insect life—a second condition which, like the chinks and crevices, may exist at Holloway Gaol, but one which is hardly necessary or unavoidable. In the local prisons on the continent, particularly in some countries, we might expect to hear of prisoners suffering as they do in Holloway, while a prisoner in a Boer camp may have much to endure inseparable from his circumstances; when, however, we meet with such a state of affairs in London we wonder whether the institution in question may not in other respects also be behind the sanitary standards of the age, while we are inclined to inquire the name of the person who is to be held responsible. Visiting justices and prison commissioners may deal where necessary with questions of construction of buildings and apparatus, but matters of administration are best presided over by an official endowed with full powers and the knowledge that his continuance in office depends on the proper performance of his duties.

DEATH UNDER AN ANÆSTHETIC.

IT is a great error to imagine that all cases in which death occurs while a patient is under the influence of an anæsthetic are of the same nature. In some cases the anæsthetic is at fault, in some the method of administration; but there are also cases, and they are by no means few in number, in which the condition of the patient is such as to make the administration of an anæsthetic an exceedingly dangerous proceeding. Of course, when possible, the use of a general anæsthetic is avoided. Of all conditions which render difficult the administration of an anæsthetic there are probably few more serious than an empyema. We have been favoured by Dr. W. H. Cooke with notes of a death under an anæsthetic which occurred in the Royal United Hospital, Bath. A man, aged 39 years, but looking at least 55 years of age, was admitted to hospital on April 24th suffering from an empyema of the right side. He had had double pleurisy for a month, and when admitted to the hospital he looked seriously ill. It was decided to operate and the anæsthetic was given four hours after admission. A.C.E. mixture was administered on a Schimmelbusch's mask, the man being on his back. At first he took the anæsthetic well, but after seven or eight minutes he commenced to struggle, and Dr. Cooke remarked that he hoped the operation would not be long as the man was very ill. As the struggling became more violent the anæsthetic was stopped. At this time the heart was beating, the respirations had not ceased, and there was no marked cyanosis; the pupils were not widely dilated, the conjunctival reflexes were present, and he had only had four and a half drachms of A.C.E. Then, quite suddenly, whilst struggling, he fell back dead, both the heart and respiration at once ceasing. Artificial respiration, strychnine, and ether were tried but in vain. At the post-mortem examination it was discovered that the right pleural cavity contained at least two pints of curdy, non-smelling pus, and there were many pleuritic adhesions and the right lung was much collapsed. The left lung was adherent all over and contained much bronchial secretion. There was a little turbid fluid at the left base, but no pneumonic consolidation in either lung. The heart, which was slightly displaced to the left, was large, flabby, and in a state of fatty degeneration; there was no valvular disease. The thorax only was examined. This case is of interest from the fact that the man died whilst taking an anæsthetic, though the death was not due to an over-dose of the anæsthetic. Four and a half drachms of A.C.E. (containing one and a half drachms of chloroform) were administered for about 10 minutes by the open method and the reflexes were never lost. The sudden death was probably due to syncope caused by the struggling in a patient with an empyema and a heart with fatty degeneration. In cases of empyema patients occasionally die suddenly on change of position, especially when under the influence of an anæsthetic, and irrigation of the pleural cavity in empyema is sometimes followed by sudden death. In some of these cases it would be safer to aspirate as a preliminary to a further operation a day or so later, when the patient might be the better able to take an anæsthetic, the heart and lung having to some extent regained their normal positions.

"MEDICALLY UNFIT."

To say that Lord Kitchener must find the variety and amount of work and responsibility inseparable from his position in South Africa as the directing head of an enormous army sufficiently onerous and overwhelming is to state an obvious platitude. But we find that Lord Kitchener has felt himself called upon amid the distractions of warfare to forward a despatch to this country protesting against the great and needless trouble that has arisen from two causes—first, that large numbers of men of the new Imperial Yeomanry have been sent for service in the field who were practically untrained and therefore unfit for it, and secondly that hundreds of these recruits have been sent out suffering from complaints and physical disabilities that the most cursory medical examination would have detected, who are filling the hospitals and are afflicted with such diseases as varicocele, affections of the heart, deafness, lameness, and defective vision, there being even one case of partial paralysis—all diseases totally unfitting the sufferers for service in the field, and in every case of such long standing that the men must have been so afflicted before passing the medical examination. There was only one thing to be done with them—namely, to discharge them as "medically unfit" and promptly to send them home again as invalids. To some extent the same neglect seems also to have characterised the raising of the first drafts of the South African Constabulary. Lord Kitchener is quite right in saying that such occurrences could not have happened if a methodical medical examination such as is laid down in the regulations had been carried out. We understand that an official inquiry into the matter will be instituted by the Commander-in-Chief and that as regards the South African Constabulary the Colonial Office will deal with it; and we are very glad to hear it. With regard to the complaint about men having been sent out who were untrained and unprepared for field service we have nothing to do; it concerns the military authorities and the purely military branch of the service. But with those found medically unfit on their arrival in South Africa the case is different. While making every allowance for occasional mistakes and oversights where reinforcements are urgently needed and men are hurriedly enlisted and the medical examinations have to be quickly, and consequently in some cases perfunctorily, performed, we cannot admit that there was any excuse for men being passed in a medical inspection as fit where such physical disabilities and complaints existed as are in the present instance alleged to have been present. Assuming the correctness of these allegations—and provided that substitutes were not used to personate recruits—there must, we think, have been manifest blundering or gross carelessness somewhere—indeed, as we cannot understand how such physical defects and disabilities could have escaped notice we are inclined to think that there must be some explanation forthcoming, because we hesitate to believe that some of the cases could, as a matter of fact, have been medically examined at all. As all these medical inspections must have been conducted, and the lists of them signed, by military medical officers or by members of the civil profession who passed the men, there should presumably be no difficulty in tracing those who are responsible, and in our opinion this course should be at once adopted. It would be interesting to know whether any special orders were issued to the examining surgeons not to be too particular but to pass as many men as possible.

SPRAYING POTATOES WITH SULPHATE OF COPPER.

IN our correspondence from Ireland an account is given, of great interest to agriculturists as well as to medical men, of a hitherto unrecorded risk of poisoning by sulphate of copper through the spraying of potatoes. In Ireland, as, indeed, is the case now in most temperate climates, the potato is a staple article of food and is cultivated with the greatest care; but, unfortunately, it is liable to be attacked by a most destructive disease caused by the parasitic fungus "phytophthora infestans," which, like the potato itself, was introduced from America but at a later date—1840. The fungus attacks the stem and leaves as well as the tubers; it appears first on the stem and leaves, as a rule about the end of July or the month of August. When confined to the stem and leaves it causes them to turn brown and eventually black, totally destroying their tissues, hence from their withered aspect the disease has been termed the "potato blight." Finally, the tubers are attacked and decay with dry or wet rot. As a result anyone driving through the country at this time of year can, if the disease is prevalent, detect its presence by smell and so by some it is called the "potato rot." The disease prevails especially when the weather is both warm and wet. It was the total failure of the crop in 1849 through this blight that contributed largely to the Irish famine of that period. To prevent its occurrence new seed has from time to time been introduced. The seventh Duke of Marlborough (grandfather of the present peer), when Lord Lieutenant of Ireland, took a warm interest in this question and his gifted son—the late Lord Randolph Churchill—made one of his earliest and most brilliant speeches in the House of Commons in the "seventies" on the question of seed potatoes. In more recent years, however, attempts have been made, with the greatest success, to prevent the potato disease by spraying the stems and leaves of the plant, generally about July, with a fluid which is destructive to the fungus. The material used is, as a rule, sulphate of copper, but it is evident from the occurrence near Ballymena of a fatal case in a person employed in spraying that in carrying out this preventive measure precautions must be used. These are (1) that persons using the spray should not have wounds or sores on their hands; (2) that they should always wash their hands after spraying or should wear long-armed gloves; (3) that they should try not to breathe or inhale the vapour, or should wear a respirator; and, finally, (4) that they should not blow down he tube of the sprayer. This is the first case of the *kind* rec

AUTHORITIES AND THE FEEDING OF INFANTS.

authorities of Norwich, as well as their of health, Dr. H. Cooper Pattin, are to be on their initiative in circulating for the of mothers a most comprehensive and practical subjects of infant feeding and the prevention of The ignorance which prevails among the majority of the lower orders on these subjects is absolutely appalling, and we as a profession cannot entirely absolve ourselves from blame for this most regrettable condition of affairs, for to a very large extent we have allowed the control of infant dietetics to pass from our hands into those of the vendors of proprietary foods whose chief object has been to sell the products of their manufacture and not to consider the ultimate welfare of the individuals for whom they cater. The leaflet which Dr. Pattin has drawn up for the instruction of mothers is thoroughly practical and to the point. He rightly insists that the best food for an infant is healthy mother's milk, but that when this supply is not available the only proper and reliable substitute is modified cow's milk. He also supplies full directions for preparing the same in accordance with an infant's requirements during the different periods of its life, and further, he warns parents against attempting to supply any other kind of food without express direction from the medical attendant. The question of infant feeding is undoubtedly one of national importance, because it is during the first year of life that the constitution of an individual is largely determined, and because, apart from hereditary influences, the method of feeding adopted during these early months of life is the chief contributory factor in the determination of a constitution which is sound or the reverse. Until such time as the nation realises its responsibilities with regard to this question it is only by the independent energy of our medical officers of health that any direct pressure can be brought to bear upon mothers or other individuals who are entrusted with the care of infants. That success can follow so simple and in an expedient as the distribution of a leaflet tions for the feeding of infants has been clearly proved in the case of Darwen; in th the medical officer of health, Dr. F. G. Hawort years ago drew up a series of regulations somewhat to those now adopted in the case of Norwich and took to see that at the time of registration of birth the pare each child were provided with a copy of his most worded directions. The result has been in e satisfactory. We hope that ere long this most san precedent on the part of Norwich and Darwen followed by all municipal authorities througho country.

A YEAR'S RAILROAD CASUALTIES IN T UNITED STATES.

FROM the annual report of the United States Commission we learn that the total number of ca to persons on account of railway accidents during the ending June 30th, 1900, was 58,185; the aggregate persons killed was 7865, and the number injured was Of railway employés, 2550 were killed and 39 injured. With respect to the three classes of these casualties were distributed thus: trainm 1396; injured, 17,571; switchmen, flagmen, and w killed, 292; injured, 3060; other employés—k injured, 5229. The corresponding figures for th year were: killed, 260; injured, 6765. The acci coupling and uncoupling cars are divided as follow men—killed, 188; injured, 3803; switchmen, flag watchmen—killed, 77; injured, 1264. In other e killed, 17; injured, 162. The casualties caused by from trains are classified as follows: trainmen, kil injured, 3359; switchmen, flagmen, and watchme 45; injured, 501; other employés—killed, 72; in The casualties among the same three classes of emp collisions and derailments were as follows: trainm 380; injured, 1867; switchmen, flagmen, and wat killed, 11; injured, 141; other employés—kill injured, 445. The number of passengers killed the year was 249, injured 4128; the corresponding for the preceding year were—killed, 239; injured, 3442. Collisions and derailments caused 88 deaths and the injury of 1743 passengers. The total number of persons other than passengers and employés was—killed, 5066; injured, 6594; these figures include casualties to those called trespassers, of whom 4346 were killed and 4680 injured. The total number of persons killed at highway crossings was 750, the injured numbered 1350, as follows: employés—killed, 20; injured, 53; passengers—killed, 1; injured, 3; other persons trespassing—171 killed; 204 injured; not trespassing—killed, 558; injured, 1090. To summarise, the figures show that out of every 399 employés one was killed and one was injured out of every 26. With reference to trainmen—including in that term enginemen, firemen, conductors, and other trainmen—it is shown that one was killed out of every 137 employed and one injured out of every 11 in service. One passenger was killed out of every 2,316,684 carried and one injured in every 139,740 carried. The summary shows that in the course of 13 years ending June 30th, 1900, in consequence of railway accidents 86,277 persons were killed and 469,027 persons were injured. The injuries reported varied from comparatively trivial injuries to those of a fatal character.

"OZONE IN THE RAILWAY CARRIAGE."

OUR remarks in an annotation under the above heading in THE LANCET of August 24th, p. 439, upon the probable advantages which would be gained by the ozonisation of the air of railway carriages have been subjected to considerable comment in the lay press. Some writers have considered the scheme impracticable on account of the enormous cost of oxygen and have estimated that this alone on the Underground Railway would be close upon a million sterling. We never suggested pure oxygen for the purpose, and, indeed, it is not necessary, the oxygen of the air would be ample. Others state that if air were used for the production of ozone, nitrous and nitric acids would be formed. Where strong ozonisation is proceeding it is true that a very small amount of nitrogen oxides is produced, just as when a flash of lightning discharges through the air, but this amount is quite insignificant in a small apparatus automatically deriving its current from the dynamo attached to the carriage wheels. We have further seen it stated that so efficient is the ventilation of the "tube" and other underground electric railways that the ozonisation of the air of the carriages would be a perfectly superfluous step. Travellers by these railways know perfectly well that the air in these subterranean places has not grown pleasanter as the popularity of the system has increased. It is sickly and a sense of relief is experienced on gaining the outside air. This should not be so if ventilation is efficient. A curious objection has been raised in one contemporary to ozone on account of its *sub-acid* smell. We have never noticed it but then we have never yet recognised a smell of this description.

DEATH OF PROFESSOR ADOLF FICK.

THE announcement of the death of the well-known physiologist, Dr. Adolf Fick, the late professor of physiology at the University of Würzburg, will be received with regret. Professor Fick was born at Cassel on Sept. 3rd, 1829, and died rather unexpectedly at Blankenberg on August 21st. He pursued his studies in Marburg and in Berlin and graduated at Marburg in 1851. In 1856 he accepted the post of professor of physiology at Zürich and in 1868 was offered and accepted the chair of physiology at Würzburg, which he held [illegible] his superannuation a few months ago. He was the author of many works, the chief of which will be found mentioned below. He was best known in this country for his "Medical Physics," which was originally published in 1856 in Brunswick as a supplement to the "Lehrbuch der Physik" of Müller-Pouillet, the third edition of which was published in 1885; by his treatise on the "Anatomy and Physiology of the Organs of Sense," published at Lahr in 1864; and by his numerous essays on muscle, one of which, recording his ascent of the Faulhorn in company with Dr. Wislicenus, is quoted in many works on physiology. In that important experiment he supplied strong evidence to show that violent and protracted muscular effort is not attended with any marked increase in the quantity of urea eliminated from the system, and hence that the muscles themselves do not suffer wear and tear but, like the mechanism of a steam-engine, are only the agents enabling the energy generated by the oxidation of the fuel, which in the body consists of the carbohydrates and fatty compounds, to be advantageously applied. Professor Fick was a man of high cultivation and greatly esteemed by the large circle of friends whom the prominent position that he held in the University of Würzburg for so many years had gathered around him. Amongst his numerous works may be mentioned his Researches on the Electrical Stimulation of Nerves, Brunswick, 1864; Researches made in the Physiological Laboratory of the University of Zürich, Vienna, 1869; The Circulation of the Blood, Berlin, 1872; Researches made in the Physiological Laboratory of Würzburg, Würzburg, 1872-1878; articles in Professor Hermann's "Handbuch der Physiologie," including one on Special Movements, others on Dioptrics, on the Accessory Apparatus of the Eye, and on the Phenomena of the Sensation of Light. He also wrote essays on Mechanical Work and the Production of Heat during Muscular Action; on Cause and Effect; and on Probabilities. He was, lastly, a frequent contributor to the leading scientific reviews.

A MUDDLING MEASURE OF BEER.

IT is one of the curious inconsistencies of English ways that the comparatively heavy beers, such as stout and ale, are sold by a liberal standard, while the lighter beers, such as lager beers, are commonly sold in accordance with a much smaller standard. Thus the "small" lager is much less than a half-pint of ale, and the "large" lager is much less than a pint of beer. Considered from an alcoholic, and therefore temperance and health, standpoint, it is a pity that this custom cannot be exactly reversed—that the light beer cannot be sold in pints and half-pints and the heavy beers as "large" or "small" on the same system as lager beer is now sold. As it is, however, a "small" or "large" bitter is never called for any more than is a half-pint or pint of lager. It would "inconvenience" the trade, we should probably be told, to adopt this order. Again, the usual price demanded for a "small" lager is 3*d*, while for a half-pint of beer it is 2*d*. (or three-halfpence, according to the class of counter over which it is sold). The amount of alcohol in the former case would be about one-seventh of an ounce, while in the English beer it would be about half an ounce, and yet 50 per cent. more money is demanded for the lager beer. A "small" lager commonly measures not more than one-third of a pint and a "large" lager not more than three-quarters of a pint, these figures corresponding to about 0·20 litre and 0 50 litre respectively. The introduction of lager beer on draught into this country brought with it the adoption of metric measures of capacity, vessels of a capacity of 0 50 and 0·20 litre being officially approved. Unauthorised measures have, however, been in use for some time as follows:—0·25, 0·30, 0·35, and 0·40 litre A proposal arose eventually that these measures should be discontinued and that 0 20 and 0 50 litre should be alone recognised as lawful. Some objection, however, was raised against this proposal by the trade, with the result that it was required that when lager beer was sold in quantities less than half a pint the vessels need not be stamped unless they were marked. Unmarked vessels containing less than half a pint need no official verification. When the capacity exceeds half a pint the vessel is bound to be stamped in accordance with the standard imperial or metric measures. The representation of the trade, therefore, met with success. But the plan anyhow is muddling which allows vessels to be graduated officially by two systems of measure, the imperial and the metric. We may be confident that for lager beer the latter system will be generally retained since it is least understood. It cannot be imagined for a moment that the sale of lager beer in half-pint and pint measures will be adopted—it would "inconvenience" the trade. We cannot understand in the least why it should be considered necessary that the metric system should be recognised for the sale of one kind of beer and not for another. And it just happens that the light beers are sold at a high price by a small standard of capacity and the comparatively heavy beers at a low price by a large standard of capacity—a system which is just exactly the reverse of the requirements of common sense and one that is directly opposed to the growth of temperate habits.

THE TREATMENT OF ANEURYSM BY INJECTIONS OF GELATINE.

THE recent deaths of two patients in Guy's Hospital from tetanus occurring while they were undergoing a course of treatment by injections of a solution of gelatine formed the subject of inquiries held by Dr. F. J. Waldo on August 26th. For some unexplained reason some of the daily papers reported these inquests under a heading or sub-heading which included the word "experiment" or "experimental." Without wishing in any way to minimise the unhappy result we must point out that there was nothing experimental—except in the sense in which all and every treatment is experimental as being tried upon a new patient—about the method. It was introduced some three years ago by Professor Lancereaux of Paris[1] and has been successful in a good many cases, while of the three patients treated in Guy's Hospital one has apparently recovered completely, and the two patients who so unfortunately died did so from an accidental circumstance, though none the less lamentable. The tetanus bacillus may infect any wound. Every precaution was taken in the sterilizing of the injections and the instruments used, and the jury, after a patient hearing, decided that the medical officer in charge of the case was exonerated from all blame. Inoperable thoracic aneurysm is a disease so distressing to the patient and so uniformly fatal that it would be a thousand pities if a treatment which has already given good results should be looked at askance because of the unforeseen having happened.

TUBERCULOSIS, BOVINE AND HUMAN.

THE most sensational episode at the recent Congress on Tuberculosis was undoubtedly the statement made by Professor Koch in which he threw doubt upon the communicability of tuberculosis from animals to man. The challenge thus thrown down has been eagerly taken up by various observers, and the controversy will continue to rage until further and numerous investigations have shown whether or no the human species can be infected with tuberculosis from the flesh and milk of tuberculous cattle. We print this week an important communication by Professor Hueppe, a perusal of which we recommend to our readers. He commences by drawing attention to Professor Koch's announcement, to which we have just referred, as being in direct opposition to his previous teaching, and argues that if Professor Koch is correct the measures hitherto taken against bovine tuberculosis must therefore be in the first place too severe and in the second place of no avail for the suppression of human tuberculosis. Professor Hueppe then proceeds to review the investigations which he himself has made on the subject and the results obtained which oppose those of Professor Koch. There are many points in this paper which will attract attention. Professor Hueppe ascribes the histological differences which exist between miliary tubercles in the human subject and the tubercles of perlsucht in the ox to a dissimilarity in the inherent quality of the tissue, and further maintains, as Professor Virchow discovered long ago, that the distinctions which Koch has now found to exist are concerned with quite different things—the one with the inherent quality of the structure, the other with the remote or ultimate developments dependent thereon; and the facts, he says, ascertained with regard to one of those do not necessarily serve for the elucidation of the other. One other remark is worthy of note, namely, that whilst the minutest difference in the organisms in cholera and now also in tuberculosis are enlarged upon by many bacteriologists in order to build up on them a theory of differences in species, in diphtheria the same investigators completely ignore constant and much greater differences in the bacteria. Professor Hueppe provisionally considers that the only thing that is certain is that the "so-called tubercle bacillus" adapts itself to the particular member of the animal kingdom which happens to be its host, and that when it has so adapted itself and has, for instance, become pathogenic for man, in that case it is not quite pathogenic for another kind of host, such as the ox; but, he adds, this limitation cannot be practically defined. He therefore urges, and we consider very rightly so, that the struggle against bovine tuberculosis should be carried on unremittingly, both on account of the economic danger and also because he still believes that the danger of bovine tuberculosis to mankind has not been disproved.

THE PUBLIC CONTROL DEPARTMENT OF THE LONDON COUNTY COUNCIL.

IN spite of, or possibly because of, Parliament, the London County Council, the metropolitan boroughs, and the lighting and water companies, London is possibly the most inconvenient and most untidy city of Europe. The streets are either muddy, slushy, or dusty; they are littered with straw, cabbage-leaves, newspaper posters, and omnibus tickets; they are constantly being grubbed up for some reason or other; barrels of beer, coals, and other goods are delivered across the footways at all hours of the day; omnibuses are allowed to block the streets pretty much as they please, and chimneys are allowed to make the air filthy because they "cannot get Welsh coal." And yet the annual return of the chief officer of the Public Control Department of the London County Council for 1900-1901 shows a gigantic amount of work. A glance at the contents page shows such subjects as lamp accidents, boiler explosions, the sale of bread, coal, and coke, inquests, diseases of animals, gas-testing, infant-life protection, petroleum Acts, weights and measures, rabies, and the smoke nuisance, to mention only a few. As regards rabies no case has occurred in London since 1898 and the last case of hydrophobia returned (of course, this means in a human being) was in 1896. The section of the report dealing with smoke nuisances is interesting. It points out that the Acts under which prosecutions may be taken practically only deal with black smoke, and also that the County Council can only deal with cases where a sanitary authority is in default. Any person, however, may make a complaint. With regard to smoke from railway engines we notice that the South-Eastern and Chatham Company were reported no less than 148 times during the year ended March 31st, 1901, the next most prominent offender being the London and Brighton Company which was reported 82 times. During the period under consideration there were 25 fatal accidents from petroleum lamps, involving a loss of 26 lives. In the coroners' courts there were held in all, during the year 1900, inquiries to the number of 8027 and there were held post-mortem examinations, exclusive of those held in hospitals, to the number of 4138. The hospital cases, in which presumably a post-mortem examination was carried out in every instance, numbered 977. The report is of great interest, but so long as London is governed by, or rather is dependent for its due regulation upon, a number of bodies all independent of each other, so long will nuisances of various kinds continue. We make no suggestion as to who should be the governing body, but that there should be one is certain.

---

[1] THE LANCET, vol. ii., 1898, pp. 1092, 1299, 1369.

THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope, received at the Colonial Office on August 22nd, states that, for the week ending August 17th, the new cases of plague in the Cape Peninsula number 0; at Port Elizabeth, coloured persons 2, natives 1, all other places 0; there were no deaths. At Port Elizabeth the deaths were as follows: coloured persons 1, natives 1, total 2; all other places 0. The total cases of plague up to August 17th were as follows: Cape Peninsula 735, Port Elizabeth 43; all other places 10. The total deaths from plague up to August 17th were as follows: Cape Peninsula 357, Port Elizabeth 18; all other places 2. The area of infection remains unchanged. The cases of plague in persons under naval and military control number 1—viz., that of a male native from the Remount Camp at Port Elizabeth. With regard to Hong-Kong, a telegram from the Governor received at the Colonial Office on August 23rd, is worded as follows: "Bubonic plague in Hong-Kong not epidemic; clean bills of health issued." In Egypt for the week ending August 18th 6 cases of plague and 3 deaths from the disease have been reported. One case, a fatal one, occurred at Port Said in a native, the other 5 cases were all European.

WE regret to announce the death from malignant disease in his seventieth year of Surgeon-General v. Coler, head of the Prussian Army Medical Corps, which took place at Berlin on Monday last, August 26th.

THE CHEMISTS' EXHIBITION.—The seventh annual Chemists' Exhibition, organised by the *British and Colonial Druggist*, was held at Covent Garden Theatre from August 26th to 30th. In addition to the usual display of drugs, perfumes, special foods, and other appliances incidental to the druggist's calling, there were some interesting novelties on this occasion. Perhaps the most striking was the enormous soda fountain, the ingenious invention of an American firm, which bids fair to become universally installed in hotels, restaurants, and other places in this country. It practically provides an unlimited supply of highly-charged soda-water, which, at the same time, may be kept cool by contact with ice. A number of various effervescing beverages may obviously be prepared by this means. Another striking exhibit consisted of a great number and variety of sponges representing a value of over £10,000. The floor of the great theatre presented a curious spectacle not unlike that of an Oriental bazaar. There was a good deal to see of interest to medical men, the members of hospital staffs, nurses, and so on. The attendance, however, did not appear to be very large, which is not surprising since the holiday season is just now in very full evidence. It might be thought that the organisers would have deemed it expedient to arrange another and a more suitable time for the exhibition which possesses interest for a wide *clientèle*.

TUBERCULOSIS, BOVINE AND HUMAN.[1]

BY FERDINAND HUEPPE.

(*Translated for* THE LANCET.)

ACCORDING to the published reports describing the International Congress on Tuberculosis held in London Robert Koch made a communication on the subject of bovine tuberculosis which fell on the meeting like a bomb-shell. From his recent researches it appears, in direct opposition to his previous teachings, that the tubercle bacillus of the human subject is not communicable to cattle and similarly that bovine tuberculosis is not dangerous to man. The measures hitherto taken against bovine tuberculosis must therefore be in the first place too severe and in the second place of no avail for the repression of human tuberculosis. Therefore, at one time the public peace of mind is disturbed by a display of the heaviest scientific artillery, backed by conclusive laboratory experiments, and then all at once the public peace of mind is again disturbed by still more conclusive laboratory experiments proving the very opposite.

For the general public most encouragement has for years been obtainable from the recognition of the important bearing which a tendency to the disease has on the development of the disease after inoculation with it has occurred. This most important side of the whole question was strangely left out of the discussions at the Berlin Congress on Tuberculosis, being only occasionally touched upon by a few speakers. This side of the question was also completely neglected by Koch in London and sufficient importance was not given to it by the speakers who were unable to follow Koch's views. Koch found, as had been ascertained beyond a doubt by American observers some years ago, that the human tubercle bacillus did not affect the ox and he probably tried to make out that conversely the tubercle bacillus of the ox is not infectious for man—that, in fact, the two organisms are not of the same species but are specifically different. The question is therefore only a bacteriological one and is not concerned with a scientific etiological interpretation of the experiments. But it cannot be known even whether this inference was not premature because the experiments were not carried far enough. The breed of the cattle which the human tubercle bacilli did not affect has still to be precisely ascertained. Even in this one must proceed cautiously. When it was proved by the researches of Bollinger, Kitt, and myself that what had been previously regarded as splenic fever of swine was a different scepticæmia and produced by quite a different species of bacterium the opinion was entertained that splenic fever did not affect the pig, and yet some breeds may be successfully inoculated with the disease. Is it therefore surprising if I ask that this point of view should be considered in the case of the cattle and pigs which serve for the experiment with tubercle bacilli? Unfortunately, I cannot do more than draw attention to this, for the arrangements and resources of my laboratory do not permit me at present to take part in these costly experiments. The accounts that have hitherto been made public lead me to believe that Koch's experiments have not been carried far enough to justify his conclusions and I must expressly keep open the possibility that the human tubercle bacillus may perhaps be able to affect some breeds of cattle, especially as before the discovery of the tubercle bacillus Bollinger had once with tuberculous material from the human subject produced true bovine tuberculosis in the calf.

But is it possible from such negative experiments on the transmission of disease to form a perfectly definite opinion as to the identity or non-identity of the exciting causes? Certainly not. For in the interpretation of the results cause and effect move in a circle according to the position which bacteriological orthodoxy happens to take up and that which has to be proved is regarded in advance as a certainty. Only the "Exposition" is taken into account, the meaning of this being that care is taken to render infection possible. This, however, is always the case in experimenting with the injection of living virulent bacilli in considerable quantity. In consequence of this Koch once more draws all the fallacious inferences which arise from regarding an inoculated disease as a natural infection. And yet these things have very little to do with one another, as we know in a laborious work of 40 years.

---

[1] [illegible]

The tubercle bacillus of man has no hold on the ox, consequently the tubercle bacillus of man and of the ox are different species! It is the same fallacious inference as Mafucci and Koch arrived at in connexion with the difference of the bacteria of mammalian tuberculosis and avian tuberculosis. These bacteria really show in their cultures distinct differences such as are not found in bacilli of different species occurring in mammals. Nevertheless, they belong to one species as obvious modifications dependent on differences of nutrition or situation. F. Fischel and myself have by purely cultural methods changed the one modification into the other and have so altered them that mammalian tuberculosis took effect on fowls and the bacteria of avian tuberculosis took effect on mammals. We have also ascertained that true mammalian tuberculosis occasionally occurs in birds (pheasants), and that true avian tuberculosis occasionally occurs in mammals (monkeys; Nocard also observed it in the horse).

And now Koch wishes us to make an intellectual sacrifice and asks us to believe that the bacteria of human and bovine tuberculosis which culturally stand near together, or, rather, are not to be distinguished, must be regarded as wholly and entirely distinct because they did not act reciprocally in his experiments on animals.

I might perhaps allude to this, that with the bacilli of bovine tuberculosis Koch produced in cattle only tuberculosis, but not the tuberculosis of the pleura peculiar to the ox—the so-called Perlsucht; his experiments, therefore, in the sense of his special interpretation, did not even prove that bovine tuberculosis affects the ox. The tubercles of Perlsucht are something so exceptional that Virchow over and over again enlarged upon their peculiarities; at one time he even did not consider them to be tuberculosis at all.

The histological differences between miliary tubercles in the human subject and the tubercles of Perlsucht in the ox, which differences, however, the majority of pathological anatomists do not deem of such importance as Virchow does, indicate a dissimilarity in the inherent quality of the tissue; but whether this inherent quality will attain its remote or ultimate developments by easy processes or by difficult ones, by the operation of pathogenic agencies of like kind or of unlike kind,—on these points the histological appearances supply no data for the formation of an opinion. Only bacteriological experiment can throw light upon the question of communicability and can explain whether in the course of inoculated disease or natural infection a biological or morphological modification and adaptation of a parasite of like kind takes place or whether only parasites of unlike kind have to be reckoned with. The differences which Virchow discovered long ago and the distinctions which Koch has now found to exist are concerned with quite different things—the one with the inherent quality of the structure and the other with the remote or ultimate developments dependent thereon—and the facts ascertained with regard to one of those do not necessarily serve for the elucidation of the other.

Many years ago I was the first to point out that with identical staining the tubercle bacilli of Perlsucht had a somewhat different form from those of human tubercle and had a certain amount of resemblance to the lepra bacilli of the human subject. Other observers also came upon this fact unintentionally, but on account of the opinions held by Koch at that time it was not recognised or not attended to, as, to give an instance, is shown by old photographs taken by O. Fränkel and Pfeiffer in Koch's laboratory. I have, of course, explained this slight variation of form as an effect of the parasite adapting itself to the special kind of nutriment which the ox supplies.

The pathological anatomist and the bacteriologist have, therefore, known for a long time that there were peculiarities in bovine tuberculosis, so that it did not surprise us when some years ago American observers announced the additional fact that bacilli from the human subject did not in general act upon the ox, as Koch has just now ascertained.

Experiments were also performed long ago which gave us more information than Koch has done. If specific differences or long and thorough adaptations to varying conditions occur they generally take a firm hold, and it is therefore, for instance, culturally or by experimental communication to animals a difficult matter to eliminate the differences between mammalian tuberculosis and avian tuberculosis. The case is, however, quite otherwise with respect to the tuberculosis of different mammals. In cultures they behave similarly. There are no difficulties whatever in the experimental transfer of such cultures from quite different mammals to appropriate animals—for instance, to guinea-pigs or rabbits; they all take immediately and to all appearance equally well, the only thing is that different quantities are often used. But in this respect the distinction between cultures from different genera of our domestic animals is not greater than between different cultures from the same genus. The cultures show varying degrees of virulence and in this particular almost no difference is recognisable between the tubercle bacilli of different mammals. Moreover, a method employed by Weleminsky may put us into a position to make quantitative work with tubercle bacilli more precise and thereby to improve the measurement of virulence with respect to rabbits and guinea-pigs. But that which we now know permits us already to conclude with certainty that as in cultures so also in the bodies of our small animals used for experimental purposes a complete elimination of whatever original differences there may be immediately takes place. But this is only possible if the exciting causes of mammalian tuberculosis, and especially the exciting causes of human and bovine tuberculosis, are identical in kind.

Strangely enough, the minutest differences in cholera and now also in tuberculosis are enlarged upon by many bacteriologists in order to build up on them a theory of differences in species, while in diphtheria the same investigators completely ignore constant and much greater differences in the bacteria.

This being established it naturally follows that the facts once more brought into prominence by Koch and his misinterpretation of the phenomena are understood, and the practical advice is given to the authorities that they should persevere with approved measures for the repression of tuberculosis in the lower animals.

As experiment immediately shows, the organism of the rabbit and guinea-pig eliminates possibly existing differences and to some extent transforms bacilli derived from the human subject or from cattle with their special features into rabbit bacilli or guinea-pig bacilli respectively, and after a few passages through the animals only the last and nothing whatever of the first are any longer to be found. The case is similar if the bacteria are continuously inoculated only upon man or upon the ox. They must adapt themselves to the media on which they grow, and if this happens they then take a firmer hold and show those peculiarities chiefly or predominantly, but these are not specific properties. The specific identity of the organism which excites mammalian tuberculosis is not abolished by virtue of these peculiarities connected with nutrition to which the parasite adapts itself physiologically and morphologically.

In tuberculosis the prospects of artificial immunisation and the preparation of antitoxins are very unpromising, but the small amount which has been collected on the subject, especially some experiments by Behring, show that even in the sense of mutual antitoxic influence the organism which excites bovine tuberculosis must be specifically identical with that of the other forms of mammalian tuberculosis.

A natural infection supposes that the infecting parasite meets a susceptible individual belonging to a susceptible species under favourable conditions. Otherwise there is no illness. In our case the infecting parasite is the tubercle bacillus, which, according to facts verified by me, is not a bacillus at all, but the parasitic growth-form of a pleomorphous fungus. As far as the protection of human beings is concerned it might seem to us to be a matter of little consequence that the bacillus pathogenic to man does not affect the ox, even if this were positively proved for all breeds of cattle and every kind of infection, but conversely it is a more serious thing, and the possibility of it is an undoubted fact, that the cattle bacillus affects man. Moreover, the cattle bacillus affects other domestic animals, and from an economic point of view it is in some localities already an anxious question to what an extent tuberculosis has increased among pigs in consequence of their consuming waste portions of milk. And who will give us a guarantee that the cattle bacillus in passing through the pig does not become a more direct danger to man?

I purposely refrain from saying more virulent. In the transmission of a bacterial poison prepared in a state of purity only its quantity per unit is to be considered, if the poison acts at all; but in estimating the virulence of a living parasite the whole of the tissue change together with the poison must be taken into account. Thereon depends its [illegible] position, its varying behaviour [illegible] nature of its host. It would, [illegible] that one parasite might be more dangerous for one particular kind of host than for another, although it forms a smaller quantity of specific poison, if only it has an increased power of attack. No one can say at present that the bacillus, pathogenic to cattle is more poisonous or more virulent, or conversely, than the bacillus which is pathogenic to man or to the pig or to the rabbit. That is only one of the contingencies in which an agreement must be come to as regards the third term of the comparison, for instance, rabbit as the animal used for the experiment, number of germs, and method of imparting the infection. The mere number of germs is not the effective part. Provisionally the only thing that is certain is that the so-called tubercle bacillus adapts itself to the particular member of the animal kingdom which happens to be its host, and that when it has so adapted itself and has, for instance, become pathogenic for man, in that case it is not quite so pathogenic for another kind of host, such as the ox.

But this limit cannot be practically defined and is to be counted so much the more for this reason, that when the bacillus gains access to a susceptible individual of a different genus, as, for instance, when the bacillus pathogenic to cattle gains access to a child, it establishes itself in the child anew and henceforth for other individuals of this genus —i.e., for mankind—there is an increased danger of more widespread infection.

The cattle bacillus certainly affects the human subject. We are in fear that it will be communicated to us from cattle by means of milk containing the tubercle bacillus. The milk is taken as food by the mouth, so that infection produced in that way ought to manifest itself as primary tuberculosis of the abdominal viscera. That is at least the general opinion at present. I consider it to be not altogether correct. Induced by certain observed phenomena, according to which in a primary outbreak of tuberculosis in the region of the upper air-passages there was extreme probability that the infection spread from the mouth (carious teeth, tonsils), Weleminsky experimented by infecting animals in like manner, and he even experimented on himself by drinking milk infected with micrococcus prodigiosus; some time after taking the milk the infective organism could be found in his tonsils It therefore appears possible that when fluids containing pathogenic organisms are drunk these organisms make their way into the system from the upper passages—as, for instance, from the tonsils—and then the primary focus of the disease is in the region of the air-passages; it is under these circumstances a mistake to suppose that there is an infection of the lung through the respiration For this reason I have a suspicion that many forms of tuberculosis are at present erroneously ascribed to respiration, whereas they ought to be attributed to infection from food, especially milk.

In a given case it is difficult to prove this post mortem, but it will be sufficient to demonstrate that the cases of primary tuberculosis of the bowel certainly represent only a minimum portion of the cases in which infection has been conveyed by way of the mouth with food. The number of these cases occurring in children is by no means so small as Koch alleged. The number of the cases may be fairly reckoned as between 25 and 35 per cent. of all the deaths of children from tuberculosis. All cases of tabes mesenterica belong to this class, and according to Heller tuberculosis of the mesenteric glands is present in almost a half of all the cases of tuberculosis affecting children. In adults primary tuberculosis of the intestine is rarer, but it has been recognised with certainty even in them. The question, however, is one for public measures to be taken with regard to it. If cattle bacilli establish themselves in even only a few cases they may open the way for a further extension of pathogenic organisms which will now more easily attach themselves to the human subject.

As a general rule tubercle bacilli occur in milk only if tubercle is already present in the udder of the cow; occasionally, of course, some other infection of the milk may be possible in consequence of want of cleanliness on the part of the herdsmen and milkers or from general want of cleanliness in the cow-house. Although tuberculosis of the udder amounts to only 2 or 3 per cent. of the cases of bovine tuberculosis, this danger is not so small if it is borne in mind that the diffusion of tuberculosis among cattle in many districts is very considerable; as a rule it affects from 20 to 30 per cent., but sometimes even more than 50 per cent. of all the cattle. Koch has therefore very greatly understated the danger of tuberculous milk and has not estimated this danger from all the points of view that require to be taken into account.

Where success has attended endeavours that have been made to reduce the mortality from tuberculosis by means of hygienic measures, as in factories, the question has only been one concerning the inhalation tuberculosis of adults. These measures have remained without effect on tuberculosis as it occurs in childhood, and this shows that the sources of the latter will have to be closed in some other way. Koch, however, would have us avoid interference with these sources and would have us concede to dairymen and milk-sellers the right of infecting children with tuberculous milk.

In places where cattle are allowed to graze at liberty, in our Alps and in marshes, uncooked milk will often be drunk with impunity; adults may do this as a rule, they being but little predisposed to intestinal tuberculosis, and even children may do it. But in the low country and in towns where the dairy cattle are always crowded together in damp cow-houses and infection spreads from animal to animal, Koch's assertion that there is no cause for uneasiness would be an invitation to carelessness which would undo all that has been accomplished.

If, as is alleged, there is no danger to human beings, who would have the courage to ask for systematic inoculation of herds of cattle with tuberculin for the purpose of freeing them from tuberculosis? As it does no harm all kinds of meat would soon be sold without more ado, and there must therefore be buyers. Of course, bovine tuberculosis does us [illegible] ones [illegible] ulous [illegible] a loss for ways and means to snap their fingers at æsthetics.'

We ought to carry on the struggle against bovine tuberculosis unremittingly, both on account of the economic danger and also because bovine tuberculosis forms an immediate danger to mankind. The question is not whether this danger is great or small, whether it has been overestimated formerly or is under-estimated by Koch now, but what has to be considered is that this danger comes upon us in a form which requires the most energetic measures of public hygiene, because the inhabitants of towns, especially the workers in manufacturing towns, are quite unable individually to protect themselves sufficiently against it.

In struggling against tuberculosis we must carefully keep in mind that not only tubercle bacilli but also human beings with their predisposition have to be taken into account. A campaign merely against the bacilli does not practically go far enough, inasmuch as the etiology of tuberculosis does not become comprehensible solely by studying the biology of the bacilli.

But the struggle against the tendency to disease is so rich in excellent promise, and in early life, especially among the children of the working-classes in towns, it offers such satisfactory prospects, that the sanitary authorities of civilised countries will do well to offer it a helping hand in the spirit of positive constructive hygiene for the bringing up of robust generations and for the carrying on of the struggle against tuberculosis assiduously all along the line.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6525 births and 4750 deaths were registered during the week ending August 24th. The annual rate of mortality in these towns, which had been 22·4, 22·1, and 21·3 per 1000 in the three preceding weeks, further declined last week to 21 6 per 1000. In London the death-rate was 19·2 per 1000, while it averaged 23 2 in the 32 large provincial towns. The lowest death-rates in these towns were 14·3 in Huddersfield, 14 4 in Bristol, 14 8 in Cardiff, and 16·3 in Croydon; the highest rates were 27·2 in Birkenhead, 27·5 in Salford, 28 5 in Newcastle, 29·1 in Sunderland, and 30·2 in Gateshead. The 4750 deaths in these towns last week included 1639 which were referred to the principal zymotic diseases, against 1725 and 1620 in the two preceding weeks; of these 1356 resulted from diarrhoeal diseases, 87 from measles, 61 from "fever" (principally enteric), 58 from diphtheria, 49 from whooping-cough, and 28 from scarlet fever. The lowest death-rates from these diseases were recorded last week in Bristol, Cardiff, Swansea, and Huddersfield; and the highest rates in Leicester, Manchester, Salford, Hull, Sunderland, and Gateshead. The greatest mortality from measles occurred in West Ham, Birkenhead, and Salford; from scarlet fever in Wolverhampton and Blackburn; from whooping-cough in Swansea; and from diarrhœal diseases in Manchester, Salford, Hull, Sunderland, Gateshead, and Newcastle. The mortality from "fever" showed no marked excess in any of the large towns. The 58 deaths from diphtheria included 27 in London, six in Leicester, four in Salford, and three in Leeds. No fatal case of small-pox was registered last week in any of the 33 large towns. There were 41 small-pox patients under treatment in the Metropolitan Asylums hospitals on Saturday, August 24th, against 13, 11, and 13 on the three preceding Saturdays; 30 new cases were admitted during the week, against four, three, and eight in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 3148 and 3101 at the end of the two preceding weeks, had further declined to 3040 on Saturday last; 273 new cases were admitted during the week, against 391, 306, and 300 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 126 and 103 in the two preceding weeks, rose again last week to 126, but were 27 below the corrected average. The causes of 45, or 1·0 per cent., of the deaths in the 33 towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Nottingham, Bolton, Bradford, and in 11 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·8, 19·2, and 19·0 per 1000 in the three preceding weeks, further declined to 17·8 per 1000 during the week ending August 24th, and was 3·8 per 1000 less than the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 14·4 in Paisley and 14·5 in Aberdeen to 18·4 in Glasgow and 20·6 in Dundee. The 566 deaths in these towns included 92 from diarrhœa, 12 from measles, nine from "fever," eight from whooping-cough, and three from scarlet fever. In all 124 deaths resulted from these principal zymotic diseases last week, against 174, 168, and 150 in the three preceding weeks. These 124 deaths were equal to an annual rate of 3·9 per 1000, which was 3·6 below the zymotic death-rate during the same period in the 33 large English towns. The fatal cases of diarrhœa, which had been 129 and 111 in the two preceding weeks, further declined last week to 92, of which 45 occurred in Glasgow, 20 in Dundee, 11 in Edinburgh, five in Aberdeen, five in Leith, four in Greenock, and two in Perth. The deaths from measles, which had decreased from 24 to 11 in the five preceding weeks, rose again to 12 last week, and included eight in Glasgow and two in Edinburgh. The deaths referred to different forms of "fever," which had been six and five in the two preceding weeks, increased last week to nine, of which four were registered in Glasgow and two in Edinburgh. The fatal cases of whooping-cough, which had been 28, 12, and 18 in the three preceding weeks, declined again to eight last week, and included six in Glasgow. The three deaths from scarlet fever corresponded with the number recorded in each of the two preceding weeks. The deaths referred to diseases of the respiratory organs in these towns, which had been 44 and 53 in the two preceding weeks, declined last week to 51, and were 31 below the number in the corresponding period of last year. The causes of 21, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin. which had been 22·4 and 19·9 per 1000 in the two preceding weeks, rose again to 24·5 per 1000 during the week ending August 24th. During the past four weeks the death-rate has averaged 21·9 per 1000, the rates during the same period being 19·4 in London and 17·7 in Edinburgh. The 176 deaths of persons belonging to Dublin registered during the week under notice were 33 in excess of the number in the preceding week, and included 34 which were referred to the principal zymotic diseases, against numbers increasing from five to 34 in the eight preceding weeks; of these 32 resulted from diarrhœa, one from scarlet fever, and one from whooping cough. These 34 deaths were equal to an annual rate of 4·7 per 1000, the zymotic death-rates during the same period being 4·6 in London and 2·6 in Edinburgh. The fatal cases of diarrhœa, which had been 23, 33, and 30 in the three preceding weeks, rose again last week to 32. The mortality from whooping-cough showed a decline from that registered in the preceding week. The 176 deaths in Dublin last week included 54 of children under one year of age and 40 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons were considerably in excess of the number recorded in the preceding week. Two inquest cases and three deaths from violence were registered; and 53, or nearly one-third, of the deaths occurred in public institutions. The causes of 14, or about 8 per cent., of the deaths in Dublin last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

The undermentioned qualified candidates for the Naval Medical Service have been appointed to be Surgeons in His Majesty's Fleet:—Thomas Brown Shaw, Percival Thomas Nicholls, Alfred Thomas Gailleton, and George Sandys Davidge.

Imperial Yeomanry.

Glamorganshire: Richard Michael Moynan to be Surgeon-Lieutenant. Lieutenant-Colonel F. W. Trevor, Royal Army Medical Corps, is granted the local rank of Colonel in South Africa whilst Principal Medical Officer of a Division. Dated 7th April, 1901.

Royal Army Medical Corps.

Colonel Richard H. Carew, D.S.O., is placed on retired pay. Dated August 10th, 1901.

The undermentioned Civil Surgeons to be Lieutenants:—James Waddell (dated June 19th, 1901), Patrick George Hyde (dated June 22nd, 1901), Andrew McMunn (dated June 25th, 1901), Alfred W. A. Irwin (dated July 1st, 1901), and George H. Usmar (dated July 5th, 1901).

The undermentioned officers are granted the local rank of Colonel in South Africa whilst Principal Medical Officers of General Hospitals:—Lieutenant-Colonel J. L. Hall (dated May 7th, 1901), Lieutenant-Colonel G. H. Sylvester (dated Feb. 12th, 1901), Lieutenant-Colonel G. E. Twiss (dated Feb. 5th, 1901), and Lieutenant-Colonel F. A. B. Daly (dated Feb. 5th, 1901).

The grant of the local rank of Colonel in South Africa made to the undermentioned officers of the Royal Army Medical Corps is continued to them whilst holding the appointments stated against their names:—Lieutenant-Colonel J. D. Edge, Principal Medical Officer, Johannesburg District and Lines of Communication, Klerksdorp-Sandspruit; Lieutenant-Colonel J. A. Gormley, whilst Principal Medical Officer of a General Hospital; Lieutenant-Colonel J. C. Dorman, whilst Principal Medical Officer, Eastern Line, Transvaal; and Lieutenant-Colonel A. T. Sloggett, C.M.G., whilst Principal Medical Officer of a General Hospital.

Army Medical Reserve of Officers.

Surgeon-Captain S. Clark, having retired from the Volunteers, ceases to belong to the Army Medical Reserve of Officers. Surgeon-Captain C. Graham Grant, 24th Middlesex Volunteer Rifle Corps, to be Surgeon-Major.

Indian Medical Service.

The following promotions have been approved by the King:—*Madras Establishment:* To be Colonel: Lieutenant-Colonel Andrew Francis Dobson. Dated May 4th, 1901. *Bombay Establishment:* To be Lieutenant-Colonel: Major Henry Wickham Stevenson. Dated April 2nd, 1901. The King has also approved of the retirement from the service of the undermentioned officers: Colonel Terence Joseph McGann, Madras Establishment (dated May 4th, 1901), Lieutenant-Colonel George Waters Bombay Establishment (dated April 23rd, 1901), Lieutenant Colonel Edward Lawrie, Bengal Establishment (dated May 17th, 1901), and Major George Herbert Fink, Bengal Establishment (dated July 13th, 1901)

VOLUNTEER CORPS.

Rifle 1st Volunteer Battalion the Buffs (East Kent Regiment) Surgeon Lieutenant H S Oliver to be Surgeon Captain

VOLUNTEER MEDICAL STAFF CORPS

The Glasgow Companies —Surgeon Captain W F Somerville to be Surgeon Major

SOUTH AFRICAN WAR NOTES

The following have been discharged from hospital to duty —Major S Hickson R.A.M C, and Captain H W Vaughan Williams R.A.M C

Major B L Mills, R A.M C, and Civil Surgeons Turton Jones and Wade are on passage home in the *Wal ool* which left Cape Town on August 21st.

Civil Surgeons Verley, Hunter and Brock are on passage home in the *Dilwara* which left Cape Town on August 24th

Princess Henry of Battenburg invited a number of invalids from South Africa to a short trip in her yacht *Sheila* recently

AFFAIRS IN SOUTH AFRICA

Whatever effect Lord Kitchener's proclamation may have had upon the burghers in inducing them to submit to the inevitable and to put an end to further bloodshed and futile suffering on the part of their countrymen it has had none on the Boer leaders and generals who have now little or nothing to lose or to gain by it As might have been confidently expected, they announce their intention of holding out to the end, although they cannot possibly deceive themselves into believing that they can ever hope to accomplish the design with which they started—namely that of uniting South Africa under an Afrikander flag The Boer generals not without reason think they can at any rate succeed in eluding capture and it is apparently hopeless to expect that anything short of that will suffice to put an end to their hostile activity Be this as it may the cold season at the Cape will soon be coming to an end and with the advent of hot weather we may expect that there will be a recrudescence of enteric fever and of other diseases among the forces in the field although probably not to anything like the extent that has taken place in the past The troops forming the army of occupation although they may expect to be harassed by fitful attacks and desultory fighting and marches in pursuit of small marauding bodies will not be generally called upon to undertake the same hard and fatiguing marches or exposed to the same extent to the heat—conditions which had previously rendered them so vulnerable to disease causes—and they will also have become more acclimatised and hardened by field service Still there has been a good deal of enteric fever during the past winter and every effort should be made to provide for the cleanliness and sanitary condition of camps and railway stations and for the provision of a good water supply together with proper means for the boiling and storage of the water As we have again and again insisted upon the soil in and around camps soon becomes fouled by occupation rendering a frequent change of site essential The long continued elimination by the kidneys of typhoid bacilli their vitality in organically polluted soil and the facility with which this source of dissemination is overlooked in camps make this obvious The sanitary work of the army in the field is always of the highest importance and to be of any use it must be systematically undertaken and thoroughly carried out Never was a greater mistake made than that of the abolition of the special post of sanitary officer with an army in the field Instead of one sanitary officer there should really be a properly organised sanitary department composed of a [illegible] ing o [illegible] tal [illegible] are located and it should be the duty of an officer of the [illegible] l to inspect the work of the latter [illegible] imes to consult with the local officers and to furnish the officer [illegible] h a summary result of his recom[illegible] to the chief of the staff at head quarters to whom and to the principal medical officer of the army he should be empowered to telegraph in case of need

DEATHS IN THE SERVICES

Fleet Surgeon William Brown R.N (retired), at Southsea on August 16th, aged 55 years He entered the service as Surgeon in 1871 became Staff Surgeon in 1882, Fleet Surgeon in 1890 and retired in 1891 He was at the bombardment of Alexandria (promoted Staff Surgeon) and served during the Egyptian War of 1882 (medal with clasp and Khedive's bronze star)

THE CELEBRATION OF ST LUKE'S DAY

To the Editors of THE LANCET

SIRS —On or about St Luke's Day the members of the Guild of St. Luke hold their annual meeting and have an anniversary service at St Paul's Cathedral. I beg to suggest that a similar service be held in every town in the kingdom on that day or the following Sunday and that a collection be taken at each of which one fifth be given to the British Medical Benevolent Fund one fifth to the Royal Medical Benevolent College, Epsom one fifth to the Society for the Relief of Widows and Orphans of Medical Men one fifth to THE LANCET Relief Fund and one fifth to Church expenses, these most deserving charities would benefit greatly by these collections St Luke's Day Oct 18th, will this year fall on a Friday

I am Sirs, yours faithfully,

Bedford August 26th 1901 HORACE F HAYNES

"WAS LUIGI CORNARO RIGHT?"

To the Editors of THE LANCET

SIRS —I do not find that Mr T B Sellors in THE LANCET of August 24th, p 565 advances any cogent argument against my views regarding the evils of pap feeding [1] His argument founded on the relative frequency of adenoids in the poor and well to-do is valueless as we have no exact data to go upon Mr Sellors says, 'It is recognised that the disease more generally affects the children of the poor But is it? Adenoids are certainly painfully common in the well to do

Mr Sellors writes "It must be apparent to those who have had much to do with babies that it is wrong to attribute the presence of adenoids to an imperfect use of the jaws' Well Sirs to me it is by no means apparent He goes on to say During the first year of life the jaws and tongue are in almost perpetual movement, when not taking the breast or bottle the child sucks its fingers or comforter' or champs so vigorously that its bib is quickly saturated with saliva I would remind Mr Sellors that my indictment against the too exclusive feeding of children on pap did not specifically refer to the first year of life but to the period between weaning and the end of the second year though as a matter of fact I am prepared to extend this period in both directions Is it not apparent to Mr Sellors that we have conclusive evidence as to the inadequate use of the jaws during early life in the fact of their defective growth and the consequent overcrowding of the teeth to which that defective growth so frequently leads?

Mr Sellors has a tender solicitude for the baby's gums, he fears lest they may be torn by hard food Has this physician in his long experience of babies ever chanced to put his fingers into the mouth of a lusty baby at its weaning time? If not, a valuable object lesson in infantile dietetics awaits him he will find the interior of the baby's mandibular apparatus better adapted for lacerating than being lacerated

But Sirs what is the use of arguing as to the practicability of giving the weaned baby food that requires substantial chewing when the question can only be decided by experience? My experience has shown me that the theory is practicable Acting on the assumption that the teeth of the young human are not for ornament merely, but for use I have long recommended mothers to give their children's teeth an opportunity of exercising their function which is to bite and chew food The result has been eminently satisfactory I believe, indeed—though I do not at present press this point—that children should be afforded an occasional opportunity of biting hard foods before the weaning time—directly, in fact, the teeth begin to appear. What is the meaning of the champing and profuse salivation to which Mr. Sellors refers—phenomena which attend the eruption of the teeth and the awakening into *functional activity* of the salivary glands? May we not regard them as the play of a normal function craving for satisfaction—as, in fact, the ineffectual chewing and insalivation of phantom morsels of food? And how is this mute but eloquent appeal met? By confining the diet to liquids and pap which slip down before the mouth has had an opportunity of exercising its newly acquired functions.

---

[1] THE LANCET August 17th 1901, p. 487

Mr. Sellors complains that I have not given any explicit directions as to the kinds of food I would give to the child. The reason is simple. I could not within the narrow limits of a letter deal with the subject in more than a general way. I hope, however, on an early occasion to enter into particulars, and to bring forward evidence which I believe will convince the most sceptical that the modern system of feeding the young human on liquid and pap, while denying him a fair proportion of food that needs abundant mastication, interferes with the proper development of the jaws and their appendages, and of the accessory cavities (the pharynx, nasopharynx, and nasal passages) and their appendages; that it is an abundant source of indigestion; that it has much to do with the causation of adenoids; and that it is largely responsible for the ever-increasing prevalence of dental caries and other affections of the teeth. When we reflect upon the many evils which follow in the wake of these diseases—deafness, semi-idiocy, pulmonary disorders, to mention only a few—it must be admitted that my indictment against the system of pap feeding is a serious one. And such I intend it to be. I am, Sirs, yours faithfully,

Wimpole-street, W., August 25th, 1901. HARRY CAMPBELL.

"HARVEST BUGS."

To the Editors of THE LANCET.

SIRS,—In his interesting letter on the above parasites in THE LANCET of August 24th, p. 562, Mr. A. Maude states that he can find no reference to them in any text-book of medicine or dermatology. If he will turn to p. 864 of Dr. H. Radcliffe Crocker's "Diseases of the Skin" (second edition, 1893) he will there find a short account of the parasite and of its effects on the skin. It is indexed under "harvest bug." M. Mégnin, whose researches are well known, calls it in "Les Acariens Parasites" "*le Trombidion soyeux.*" Dr. Crocker also refers to the two American species of harvest ticks described by Professor Ritz of St. Louis. I have seen severe pustular and crusted lesions about the legs in two cases, both young women, who had received the attentions of the harvest bug.—I am, Sirs, yours faithfully,

Upper Gloucester place, N.W., August 27th. GEORGE PERNET.

THE USE OF A LINEN BAG IN ETHER ANÆSTHESIA.

To the Editors of THE LANCET.

SIRS,—The apparatus invented by Clover and variously modified since for the administration of ether is such an admirable one that I do not know that we need ask for a better as a medium for ether-giving save in one particular and that a most important one—viz, the rubber bag. Although obviously possessed of some objectionable features the rubber bag has been accepted as part and parcel of the necessity of things and remains as an unclean but indispensable despot in the administration of ether in this country. Without doubt the open method of giving ether on a mask or cone is too slow in its effect to be of real practical use, and it is this slowness which has necessitated the use of the bag in question. The argument is that to produce and to maintain ether anæsthesia you must have the asphyxial element present; to this end you must exclude air and thus the rubber bag. I believe this to be a wrong and mistaken conclusion, as I shall afterwards show. The objections I would make to the rubber bag are—first, that it is apt to produce more of the asphyxial element than is desirable—viz., cyanosis; and, secondly, that it is unclean.

As regards the first, considering that the *raison d'être* of the rubber bag is to introduce the asphyxial element, it is not quite fair to charge it with producing a lividity which is so far intended, but it often does more; even in the best of hands it occasionally produces cyanosis to a degree that cannot be otherwise than a strain on the right ventricle, and certainly begets a frothy condition which is undesirable even if it does not lead to further trouble. If it were possible to remove this reproach of cyanosis and its consequent troubles from ether anæsthesia nearly all the objections to it would be groundless, and this can be done by using instead of the rubber bag one made of linen which I have devised and describe below. The second objection, that of uncleanliness, has doubtless presented itself to every anæsthetist who ever thought of the condition of his rubber bag and yet I know of no way of avoiding it. It is no mere sentimental objection that the last patient who breathed into the bag was the subject of intestinal obstruction and had a foul fæcal odour in his breath or was a sufferer from carcinoma of the œsophagus or tonsils. For the last two or three years I have been in the habit of meeting these objections by rinsing out the bag well with water, some antiseptic occasionally being added, after each operation, thus ensuring as much cleanliness as possible, and so far as the avoiding of cyanosis is concerned I have dispensed with the bag when I could, allowing the patient to breathe through the open inhaler, resorting only to it when this proved insufficient. On the whole these means met the case fairly well, but while modifying the objections they did not entirely remove them.

In America where ether is the anæsthetic mostly in use a towel folded cone-shape and covered or not by a thin waterproof is employed and apparently does well, although it finds little favour in this country. Mr. Mayo Robson who was recently in the United States came back much impressed with this mode of administration and urged me to try it. It did not, however, appeal to me; it seemed lacking in precision after having been used to measuring the ether given through a Clover apparatus. It occurred to me, however, to substitute a linen bag for the rubber one and this has proved itself to be so well adapted for the purpose and so completely meets the objections to the ordinary rubber bag that I should like to call the attention of the profession to it. I have tried it now in a sufficient number and variety of cases to enable me to pronounce it a success. The bag is made of a fine linen known as "holland" and is shaped somewhat like the ordinary bag. The body of the bag I have had made of three pieces accurately sewn together, a collar of the same material with a tape attached to be slipped over the ordinary Clover bag-mount and tied there completes it. As may be guessed this bag does not fill and empty, as does the rubber one, to the breathing of the patient, it is simply put on in a "bunched out" condition and only a slight rise and fall tells of the expiration and inspiration. My experience with it is that the patient goes under very quietly, I may say with almost suspicious quietness; there is none of the usual noisy breathing, almost no salivation, and absolutely no lividity. Abdominal heaving is also absent, the anæsthesia is as quiet as with chloroform. The time occupied to produce anæsthesia is, of course, longer than with the rubber bag, varying from seven to 12 minutes. The corneal reflex seems to be lost disproportionately soon. The amount of ether consumed is also considerably more, during the first 15 minutes about twice as much being used, but in a prolonged anæsthesia the disproportion is not so great, as will been seen in a note of the appended cases. There is another very great advantage in the use of the linen bag in that the anæsthetist holds a trump card, so to speak, in the shape of his chloroform drop-bottle. Should the patient prove hard to anæsthetise or threaten to come round he can sprinkle a little chloroform on the bag, selecting by preference the place where the linen shows the most marked rise and fall of the breathing. A fresh bag or freshly-washed bag is used for each case; it can be slipped on to the ordinary Clover mount and tied in position in half a minute. In practice I turn the Clover gradually, but compared to the old mode rapidly, on to full and keep it there or thereabout till sufficient anæsthesia is produced. Later a less concentrated vapour will be found enough. Perhaps one is usually inclined to over-value one's own discovery, but in this case I do not think that I make too much of it in saying that it ought to supersede the rubber bag completely. A fresh, clean, aseptic bag for each patient is a thing to be desired when it can be had at the cost of washing. The entire absence of even lividity will commend it to every anæsthetist and the possible resort to chloroform in addition, without change, is a happy incident. I may say that the bag has been used by several other men here with the same good results. The bags can be had from Messrs. Reynolds and Branson and Mr. R Rauschke of this city. I might add that for further asepsis the Clover chamber can be boiled or immersed previously to operation in a 1 in 20 hot carbolic solution. The mask I am having made of thin brass, nickelled, with a detachable red rubber face-pad so that the whole can be rendered as sterile as the operator's instruments.

Note of Cases.

Date.		Operation.	Amount of ether.	Time of administration.	Average time per ounce.
July	1st.	Choledochotomy, &c.	11 oz.	1 hr. 40 min.	1 oz. in 9 min.
,,	2nd.	Nephrectomy.	5 ,,	1 ,, 45 ,,	1 ,, ,, 9 ,,
,,	2nd.	Appendectomy.	4 ,,	1 ,, 40 ,,	1 ,, ,, 10 ,,
,,	3rd.	Ovariotomy.	7 ,,	1 ,, 48 ,,	1 ,, ,, 7 ,,
,,	6th.	*Gastro-enterostomy.*	4 ,,	1 ,, 40 ,,	1 ,, ,, 10 ,,
,,	10th.	Exploratory and colotomy.	4 ,,	1 ,, 35 ,,	1 ,, ,, 8 ,,
,,	10th.	Breast amputation	4 ,,	1 ,, 45 ,,	1 ,, ,, 11 ,,

In all, I have had some 50 cases similar to the above; average time to procure anæsthesia being 10 *minutes*; average amount of ether being one ounce per eight minutes.

I am, Sirs, yours faithfully,

W. McGREGOR YOUNG, M.A., M.D. Glasg

Leeds, August 27th, 1901.

"THE TREATMENT OF PHTHISIS BY MEANS OF ELECTRICAL CURRENTS OF HIGH FREQUENCY AND POTENTIAL."

To the Editors of THE LANCET.

SIRS,—In your excellent report of my paper on the above subject, which I read before the Medicine Section of the British Medical Association at Cheltenham, I am reported to have said: "He did not think the bacilli were killed by the current." The bacilli are not killed but are stimulated to *very excessive overgrowth which affects them adversely by* attenuation. The bacilli act in the following manner. Within a few days they begin to *increase* and after a week or two become greatly increased in numbers; they soon form clumps and later get misshapen, *short and stumpy*, and generally curved, and stain far more readily than before. After a time they decrease, and later, when the patient is obviously better in every respect, they may cease entirely, but a few may reappear from time to time. At a stage of the treatment large numbers of leucocytes, &c., are generally found. The temperature naturally follows the increase in numbers of the attenuated bacilli and increase in body weight follows the decrease of bacilli.

I am, Sirs, yours faithfully,

CHISHOLM WILLIAMS.

Bedford-square, W.C., August 24th, 1901.

MASSAGE IN JOINT INJURIES.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 2nd, 1898, p. 465, I explained and advocated a treatment for certain recent injuries of joints by *massage and movement.* I have now the pleasure of noting that some of the more prominent members of the medical profession have adopted and are endorsing the views which I then put forward—views which I had not seen had been previously advocated. Last year Mr. (now Sir William H.) Bennett spoke favourably of the treatment and this month at the meeting of the British Medical Association held at Cheltenham Mr. Howard Marsh has been giving it his general approval, so that we may fairly anticipate that it will come, with more or less modification, to be generally adopted by the profession. Mr. Marsh says, "The after-treatment of dislocations has of late years undergone a great and very advantageous change. In the case, e.g., of the shoulder-joint the arm is no longer bandaged to the side for a fortnight or three weeks, but passive movements and massage are regularly used after the second or third day." This is a line of treatment which very nearly corresponds with the principle I advocated nearly three and a half years ago. I hold that a welcome result of the adoption of this line of treatment will be a great lessening of the bone-setting industry, the annoyance of which to the profession is well known and whose operations have often been attended with a certain measure of success, in my opinion chiefly owing to the former faulty treatment of these injuries.

One of the most interesting and successful cases which I have treated on the above principles was the case of a volunteer who dislocated his right elbow. *His forearm was at right* angles to its proper position and the bones of the forearm were *so much displaced that there was great danger of the* skin rupturing. The ligaments must have been very much injured. Although there was a good deal of inflammation and swelling afterwards I persevered in the treatment, so *that within a* comparatively *short time he was at work,* and now his joint is as good as it ever was.

I am, Sirs, yours faithfully,

Galashiels, August 26th, 1901. WILLIAM DOIG, M.D. Edin.

THE TEMPERATURE OF INGESTA AND ITS INFLUENCE.

To the Editors of THE LANCET.

SIRS,—I have never met with any observations on the temperature of food and drink as taken into the body under ordinary circumstances. It may be of some interest to call attention to the matter now that the hot weather is upon us and one's efforts are directed towards keeping cool. Temperatures which cannot be borne by the external *skin* are easily tolerated by the mucous membrane of the alimentary tract to an extent which may surprise *many.* For example, taking an ordinary typical meal, I found that the following temperatures were registered (Fahrenheit): meat, 115°; *beans,* 132°; *potatoes,* 150°; and fruit pie, 130°. Any of these were well borne by the mouth, even the potatoes. I found that the average temperature of hot tea was 135°, above this the tea could be sipped up to 142° but could not be drunk with comfort. It was impossible to keep the finger in contact with any of these articles for more than a moment. These few figures will suffice to emphasise the lesson which I wish to draw, that if we want to keep cool hot meals should be avoided. They also help one to realise that the stomach may be seriously affected by taking our food at such high temperature, as witness the frequency of gastric ulcer in cooks supposed by many to be due to the tasting of hot dishes.

I am, Sirs, yours faithfully,

JAMES ROOTH, M.R.C.S., L.R.C.P.

Oxford, August 25th, 1900.

"HAY FEVER: ITS REMEDY."

To the Editors of THE LANCET.

SIRS,—In answer to Mr Lennox Browne's suggestion in THE LANCET of August 24th, p. 565, of tabloids of suprarenal extract for use in hay fever, I may say that I gave them a fair trial about 18 months ago but ceased using them owing to the great difficulty in dissolving them in water. I have for the past 12 months used the *mixture* of chloretone and suprarenal, a preparation which I find does not decompose for a long time; if the mixture is diluted more chloretone *should be added to insure* preservation. Dr. Clement Dukes does not state what class of cases of hay fever are benefited by the use of adrenalin chloride; my experience teaches me that only those cases with some intra-nasal abnormality—e.g., hypertrophic rhinitis, spurs, &c.—are improved by the use of extract of suprarenal capsule and a large majority of these patients can be permanently relieved by suitable intra-nasal treatment

I am, Sirs, yours faithfully,

Lincoln. A. STANLEY GREEN, M.B., B.S. Lond.

RE "BLUE URINE."

To the Editors of THE LANCET.

SIRS,—I have just learned that the cause of "blue urine" in a case reported in THE LANCET of June 1st, 1901, p. 1535, was due, after all, to a pill of methylene blue given my patient for the pains in his back by a friend who takes them "for his kidneys." My patient had not the least recollection of the incident and was much alarmed at the consequence Hence his persistence in awaiting my return from visiting. My patient's statements were quite *bonâ fide* and I consider my diagnosis, though erratic, quite justifiable.

I am, Sirs, yours faithfully,
JOHN GOOD.
Stockport, August 23rd, 1901.

"THE TIMES ARE TROUBLOUS."

To the Editors of THE LANCET.

SIRS,—Under the above heading "G. P." in THE LANCET of July 27th, p. 229, mildly describes the lessening income of the profession. I think his letter is admirable on all points but that of describing how hospitals diminish our incomes in manufacturing districts which he has omitted. England's population, I may say, is a working-class one and it is with working people we have largely to deal and all look to the cheapest and easiest way to procure medical aid; hence employers of labour find that the cheapest and readiest means of cheapening the employer's liability is to subscribe to the local hospital if there is one, and if not, to found one, so in that way their pockets do not suffer by the Act. Again, the working man objects to approach the medical man's well-painted hall-door, and in preference to bringing his minor ailment there he finds a shilling lotion or a bottle of physic from the chemist does all he requires. Minor ailments the chemist prescribes for and thrives on, hence he lives; and the medical man who paid for his profession becomes a squire at the expense of his wife's fortune or industry. Quite satisfied with this state of affairs the medical man of to-day has little thought for his poorer brethren whom apparently he detests and will persecute, whereas the chemist who is his enemy oftentimes he befriends and publicly approves of his prescribing qualities rather than help his brother who loves and lives by his profession.—I am, Sirs, yours faithfully,

August 21st, 1901. COLCHESTER SHILLING.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Continued Rise in the Plague Mortality.—Enormous Expenditure on Famine Relief Works.—Medical Officers remaining in China.—"Sutti."—The Report of Plague in Calcutta.

THE plague mortality for India continues to rise. For the week ending August 3rd 2003 deaths were reported compared with 1912 for the previous seven days. In the corresponding week last year the deaths were only 259. The Bombay Presidency is the chief sufferer and returns 1730 deaths with in addition 136 deaths for Bombay city. There has been a gradual increase in this city for some weeks past. The Mysore State (especially Mysore city) has been also severely attacked and reported 109 deaths for the past week. Dropping cases continue in Karachi, and the general mortality in Poona is ominously rising, although up to the present only a few cases have been discovered. Calcutta continues to return between 10 and 20 cases each week, but the general mortality has been exceptionally low for more than a month.

The magnitude of the relief works undertaken during the late famine is shown in the expenditure on relief works controlled by the Public Works Department, which amounted to Rs. 22,297,856 (equal to nearly a million and a half sterling). Of this amount 97 lakhs were incurred in Bombay, 91 lakhs in the Central Provinces, 21 lakhs in the Punjab, and 12 lakhs in Rajputana. There were 29 lakhs spent on irrigation works and nearly 131 lakhs spent on "communications," 29 lakhs on railway construction, and 55 lakhs on "miscellaneous public improvements."

The following is a list of the medical officers remaining in China with the winter garrison. Principal medical officer: Colonel O'Connor, I.M.S. No. 15 British Field Hospital: Captain Browning, R.A.M.C., Captain Hayes, R.A.M.C., Captain Mitchell, R.A.M.C., and Captain J. E. Brogden, R.A.M.C. No. 3 Native General Field Hospital: Lieutenant-Colonel J. A. Burton, Captain F. D. Browne, Lieutenant V. H. Roberts, Lieutenant D. N. Anderson, and Lieutenant A. E. Walter. No. 51 Native Field Hospital: Major Moore, Captain Sargent, Captain Hunt, and Lieutenant G. C. Beamish. No. 57 Native Field Hospital: Major W. White, Major J. T. Ozzard, Captain H. R. Cleveland, and Lieutenant G. R. Stewart. No. 63 Native Field Hospital: Major H. Greany, Major Ricketts, Captain H. Wall, and Lieutenant W. E. McKechnie. Base Medical Store Depôt: Major J. T. Daly. 14th Sikhs: Captain E. H. Sharman. Hong-Kong Regiment: Lieutenant McGaw. 1st Batt. 4th Gurkhas: Captain Lindesey. 6th Burma Battalion: Captain R. G. Turner. 2nd Rajputs: Captain C. Hudson. 30th Bombay Infantry: Captain G. McPherson. On special service: Major C. C. Manifold All the above, with the exception of the British field hospital, belong to the Indian Medical Service.

The census returns show that the European population within the limits of the Calcutta municipality was 8152, of of whom 2203 were females. There are 1098 more in Howrah and some 250 more in the suburbs. These figures are exclusive of British soldiers who numbered 1450.

The practice of "sutti," or the burning of a widow on the general pyre of her husband, having been made a crime for over 70 years by the Indian Penal Code, is now seldom heard of. A recent case, in which the act of suicide by the widow was aided and abetted by caste-fellows of the widow, shows that the desire to revive this terrible practice is not yet extinct. The husband had died from plague.

The report on plague in Calcutta during the past year has been supplied to the press. The outbreak this year seems to have coincided in season and duration with that of last year, and the mortality has been very similar. There were 7016 deaths and the case-mortality was 90·5 per cent. This is much the same as before and indicates that a large number of living cases fail to come to the notice of the authorities. Subsidiary reports by the district plague officers form a special feature of this issue There is, perhaps, nothing new recorded, yet the information collected is interesting. The course of the outbreak is clearly recorded by charts, and although the report is much shorter than that of last year it is condensed by the avoidance of repetition. One fault, however, lies in the selection of arbitrary dates for the commencement and ending of the recent outbreak, so that it is with difficulty figures for corresponding periods in previous years can be compared. The evidence as to the value of disinfection is very meagre and it would almost seem that the disinfection as practised had been a failure. It is also certainly unfortunate that only 107 persons were inoculated during the entire outbreak.

Calcutta, August 5th.

THE WAR IN SOUTH AFRICA.

(BY A SPECIAL CORRESPONDENT.)

THE Imperial Yeomanry Hospital has during the past month been very full and it has sometimes been difficult to find room for the different convoys as they arrived, and to do this beds vacated in the morning have been filled in the afternoon. The majority of the cases are of slight ailments Enteric fever is dying down again after the winter months, and although fresh cases are continually cropping up they are comparatively few in aggregate numbers.

On July 31st Surgeon-General Wilson, A.M.S., inspected the Imperial Yeomanry Hospital and expressed himself as delighted with the arrangements of the hospital. Together with Lieutenant-Colonel Kilkelly, R.A.M.C. (Grenadier Guards), and Dr. H. D. Rolleston and the members of the medical and surgical staff he visited the different sections of the camp. Whilst passing through the enteric fever division he came across an officer who some months before had passed through a previous attack at Deelfontein and he remarked that he had seen several patients who had had two or three attacks of enteric fever, in some cases ending fatally. He went on to say that this was a very strong argument against any system of preventive inoculation ever being of any service.

Passing on to the medical section, giving a kindly word of encouragement to the different patients as he passed, he arrived at the ward set apart for dysentery cases, where Dr.

G. E. Richmond, by the kind permission of Lieutenant Colonel Kilkelly and Dr Rolleston, had been enabled to test the efficacy of the new treatment of this terrible complaint by sulphur Several patients were pointed out to him who had been admitted passing from 20 to 30 motions a day consisting of nothing but blood and mucus, who had been practically cured in two or three days by the administration of 20 grains of sulphur combined with five grains of Dover's powder The fact that after treatment with sulphur relapses and chronic diarrhœa were less likely to occur was considered to be a valuable factor in favour of the new treatment. Several cases of chronic diarrhœa following dysentery were shown which had greatly benefited by a course of sulphur

After visiting the general offices, kitchens x ray room surgical divisions, and sanatorium for the reception of phthisical patients, Surgeon General Wilson expressed his entire approval with the arrangements and hoped that he would be able to keep on the hospital as a Royal Army Medical Corps Hospital when the Imperial Yeomanry Committee gave it up There are rumours that the Imperial Yeomanry Hospital at Pretoria is to close on Sept. 30th, and that the hospital at Elandsfontein, which is now being enlarged to 100 beds will carry on the work of the Imperial Yeomanry Hospital in South Africa until the war is at last finished

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

Guardians and Vaccination Prosecutions

AT a meeting of the Burnley Board of Guardians held on August 21st a resolution was passed by 21 votes to nine, four members not voting directing the vaccination officer to abstain from prosecutions until the guardians authorise him specially to do so " It is possible, perhaps, to see what the mover of the resolution meant to say in spite of the confusion as to grammar under which he was suffering, for he said "the vaccination committee instructed their officer last June not to take any further proceedings and yet he had recently summoned a number of parents in defiance of those instructions" Mr Jenner Fust who was present, pointed out that the resolution would be without any power and would leave the vaccination officer in exactly the same position as before, and read an extract of a circular of the Local Government Board which stated that "having regard to the decision of Mr Justice Wright in the leading case on the subject, and the opinion given by the law officers of the Crown, the duty of instituting and conducting proceedings was imposed on the vaccination officer," under the Vaccination Acts passed before the Act of 1898 He also explained to the guardians that it was the duty of the vaccination officer to take proceedings without any order from them, but that it was their duty "to see that he did so, and if he did not to report it to the Local Government Board." In spite, however, of the opinion of Mr Justice Wright and the law officers of the Crown and of the clear exposition of Mr Jenner Fust these sapient but ungrammatical guardians passed the resolution from which the essential part has been quoted In order to stultify themselves still further a second resolution was passed "requiring the vaccination officer to request leave of the magistrates to withdraw the summonses against six parents which have already been before the court and adjourned " The serious part of the matter is the open defiance of the law by the Burnley Board of Guardians and the unpleasant position of the vaccination officer who is thus incited and indeed required, by his board to break the law

The Water supply of Manchester

The continuation of dry weather keeps the water supply of Manchester too low to be quite satisfactory and it is still thought advisable to stop the supply at night. There is no doubt plenty of water in Thirlmere but only one pipe is available and it will be some time before more can be obtained from that source The old reservoirs at Woodhead have therefore as yet lost none of their importance. It was stated the other day that altogether there was only enough water for 38 days The weather seems now to be breaking and there promises to be abundance of rain, so that it seems unlikely that the present restrictions will have to be increased. The dry weather has affected the milk-supply, and the other day a man who was fined 40*s* and costs at the City Police Court pleaded that he was losing customers from inability to supply them and that the water added to the milk "was not put in for fraud, it was only to prevent ruination " The scarcity of water has led to a second appeal from the chairman of the Bury and District Joint Water Board for the exercise of caution in its use It is stated that the ground is so dry that recent rains have not reached the reservoirs A wide area is affected, including Bury, Radcliffe, Whitefield, Haslingden, and Rawtenstall In the last named 120 houses on one estate supplied from a local reservoir which is now completely dry are it is said, "completely without water "

Mid Cheshire Isolation Hospital

Mid Cheshire has long been dallying with the question of providing an isolation hospital for infectious diseases and has succeeded almost as well as a Chinese or Turkish diplomatist could have done in postponing the establishment of one for several years Last November, however, the Cheshire County Council made an order that the Northwich Rural Council and the Northwich Winsford, and Middlewich Urban Councils should be formed into a joint hospital district and should erect a hospital This was to have come into force last January but nothing has been done On August 22nd a communication was received by the clerks of the various councils confirming the order made by the Cheshire County Council, producing, it is said something like consternation in Mid Cheshire The order comes into force on Sept. 1st and will necessitate the expenditure of £15,000, or, as some say, £20 000 Should a hospital satisfactory to the county council not be erected within a year the present hospital committee of 14 will be replaced by one of 18 members, 10 to be elected by the county council and eight by the four local councils interested The committee thus constituted would no doubt be strong enough to overcome the hitherto successful *vis inertiæ*

Anthrax in Cheshire

An outbreak of anthrax has occurred at a farm in Cheshire where 100 cows are kept and from which large quantities of milk are sent to Manchester Three cows and a pony are stated to have died from the disease Every precaution as to isolation has been taken "and American food stuffs are being analysed " So far the cause of the outbreak has not been discovered

August 27th

WALES AND WESTERN COUNTIES

(FROM OUR OWN CORRESPONDENTS.)

Diphtheria in Bristol in 1900

IN his recently issued annual report to the council of the city of Bristol the medical officer of health, Dr D S Davies deals at some length with the outbreak of diphtheria which prevailed in Bristol during 1900 There were notified during the year 512 cases, and 103 terminated fatally, the case mortality being 21 per cent. and the death rate 0·3 per 1000 of the total population. In the whole of England and Wales the death rate during 1900 from diphtheria was 0·29 per 1000 In addition to the 512 notified cases material from 318 other suspicious cases were examined with negative results The economic value of this bacteriological examination is thus very markedly demonstrated for without such examination the city authorities would have been put to the expense of keeping these 318 cases under observation carrying out disinfection and possibly removing a certain proportion to hospital Mr J C Heaven first drew prominent attention[1] to the persistent presence of the Klebs Löffler bacilli in the nasal cavities and Dr Davies in endorsing this view considers that the bacilli may exist and often do exist, in almost pure growth in the nasal cavities of school children who have been exposed to the infection without affecting the throat and without producing any constitutional symptoms or any obvious signs of illness but capable of spreading the disease to other susceptible persons Dr Davies deplores the lack of isolation accommodation in the city and considers that if it had been possible to secure isolation at an earlier period of the outbreak many lives might have been saved. Antitoxin was supplied gratuitously by the corporation to those persons unable to pay for it. Only 70 of the 512 cases were removed to the Ham Green Fever Hospital, and of these 12, or 17 per cent., terminated fatally.

---

[1] Public Health vol viii, p 211

The New Dietary at Cardiff Workhouse.

At the meeting of the Cardiff Board of Guardians held on August 24th the master of the workhouse reported upon the cost of the new dietary and stated that, based upon the experience of the three months during which the dietary had been in operation the additional cost of its adoption would amount to £145 per annum. He further said that there was a much more varied diet, almost a free table so far as the supply of bread was concerned, scarcely any waste of bread, no complaints from the inmates, but some extra work for the officials. At Bristol the estimated saving amounts to over £500 yearly.[2]

Death of Mr. John Griffith Lock.

By the death of Mr. J. G. Lock, M.A. Cantab., L.R C.P. Edin., M R.C.S. Eng., L.S.A., J.P., at Tenby on August 18th the medical profession is South Wales loses one of its most prominent members. For two years he had borne with patient courage an illness resulting from malignant disease of the tongue and which he himself was well aware could terminate only fatally. Mr. Lock was born in the year 1840 in Tenby where his father acted for many years as town clerk. He was educated at Harrow and at Trinity College, Cambridge, taking his degree as Master of Arts in 1866. He received his medical education at Addenbrooke's Hospital and at St. Bartholomew's Hospital where he was resident obstetric officer in 1867 and house physician in 1868. In the latter year he began to practise in Tenby and in 1873 was appointed by the corporation as the first medical officer of health to the borough, a position which he resigned early in the present year. To him is no doubt due in a great measure the admirable system of drainage and the plentiful supply of water which have been provided for Tenby. The Tenby Cottage Hospital was established in the year 1871 almost entirely through Mr. Lock's instrumentality and he always took the greatest interest in the welfare of the institution. He had an extensive practice among the residents and visitors of Tenby and of the surrounding district, and was one of the poor-law medical officers for the Pembroke Board of Guardians. Mr. Lock was an ex-president of the Monmouthshire and South Wales Branch of the British Medical Association, and a justice of the peace for the county of Pembroke. In 1882 he was W M. of the Tenby Lodge of Freemasons, and also held office in the Five Arches Lodge of Mark Master Masons and as P.P.G.R. of the Province of the Western Division of South Wales. Many of his colleagues who have from time to time visited Tenby have reason to remember with gratitude the manner in which Mr. Lock looked after their welfare during their sojourn in the town. He had a charming personality and a most unselfish thoughtfulness for the comfort of others. He was twice married, and his second wife survives him. The funeral, which took place on August 20th, was of a public character and is said to be the largest ever witnessed in Tenby.

August 26th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Sanitary Association of Scotland.

THE twenty-seventh annual congress of the Sanitary Association of Scotland is to be held at Paisley on Sept. 5th, 6th, and 7th. The President will be Dr. R. Farquharson, M.P., of Finzean, and Professor John Glaister (Glasgow) and Mr. K. Cameron, chief sanitary inspector, Aberdeen, will be vice-presidents. The presidential address will deal with the subject of Domestic and Official Sanitation. Professor M. Hay, M.D. Edin., medical officer of health of Aberdeen, was to have opened a discussion on the Value of Hospital Isolation in the Case of Scarlet Fever, but he will be prevented from attending. The annual dinner will be held in the Grosvenor Restaurant, Glasgow International Exhibition, on Sept. 5th.

Aberdeen Medical Practitioners and the Drug Trade.

Those medical men in Aberdeen who have drug shops in addition to their professional business are, it is understood, to take no notice of the deprecation of such practices published in THE LANCET by the senatus of Aberdeen University. With the absence of epidemics trade in all drug shops in the city is at present very dull.

Common Lodging-houses in Aberdeen.

Aberdeen Town Council has resolved to apply to the Local Government Board for Scotland for authority to raise the minimum charge from 4*d.* to 6*d.* per night, so as to include more premises in the category of "common lodging-houses" as defined in the Scotch Public Health Act. This new departure may lead to some increase of business at the corporation lodging-house—which, in fact, is financially a white elephant—but has been anticipated by several individual proprietors of lodging-houses for the nomade or poor class having previously raised their charges to 7*d.* per night.

The British Association at Glasgow.

The arrangements for the meeting of the British Association which will commence at Glasgow on Sept. 11th are now in a forward condition. The university authorities have placed all the buildings at Gilmorehill at the disposal of the Association and there will in this way be provided ample accommodation for the various sections as well as for those charged with organising and executive duties. The municipality have taken an active share in the necessary arrangements and many of the distinguished scientific visitors will be entertained by private citizens. The new President, Professor A. W. Rücker, will deliver his address on the evening of the 11th and this, of course, will be the first official meeting of the Association. On the afternoon of the 12th Professor and Mrs. Cleland will give an "At home" on the occasion of the opening of the new anatomical class-room, laboratory, and museum at the university and in the evening the Lord Provost will officially receive the members of the Association at a conversazione to be given in the municipal buildings. Among the social functions of the meeting there will also be garden-parties by Lord Blythswood at the Botanic Garden, and by Lord Overtoun at his country seat at Overtoun. The attractions of the exhibition, which can now count upwards of 6,000,000 of visitors, will doubtless also receive some share of attention, more especially as the authorities propose to hold a conversazione in the new art galleries which are included within the exhibition grounds. As already stated, the sections are to meet at the University, but the President's address and the public lectures will be given in St. Andrew's Hall. The lectures already announced include one by Professor William Ramsay, F.R.S., on "Inert Constituents of the Atmosphere," and one by Mr. Francis Darwin, F.R.S. on "The Movements of Plants." Professor Mackinder of the Oxford School of Geography will give a special lecture to working men. The excursions are to be numerous, and several of them are to have a definite scientific object; the geological section, indeed, has organised a tour which is to extend over a week and is to include a visit to the famous geological formation at Assynt. Handbooks dealing with the scientific, industrial. and other features of Glasgow and the valley of the Clyde have been prepared and will be placed in the hands of members. All the omens suggest a highly successful meeting.

Report on Scottish Local Government.

The sixth annual report of the Local Government Board of Scotland contains a reference to the late outbreak of plague in Glasgow. Attention is drawn to the fact that the city local authority on the discovery of the first case of plague at once directed all their resources to prevent the extension of the disease, and with the gratifying result that the epidemic was confined to a single district of the city, with the exception of two cases which occurred in the neighbouring borough of Govan. Excluding three fatal cases of probable plague, but including the Govan cases, it is found that there were in all 29 patients attacked by the disease, of whom nine died, the first on August 27th and the last on Oct. 6th. On Nov. 5th the medical officer of Glasgow was able to report that the last case had been dismissed from the hospital, and an order by the Board declaring the port free from plague infection was issued on the 14th. In transmitting this order to the local authority at Glasgow the Board recorded their high sense of the skill and energy with which the outbreak had been met, and expressed the opinion that Great Britain was under a heavy obligation to Glasgow for the promptitude and efficiency of the sanitary measures taken in the presence of a national emergency.

---

[2] THE LANCET, August 24th, 1901, p. 567.

The late Dr. Adam Lawson Kelly, Glasgow.

By the painfully sudden death of Adam Lawson Kelly, M.D. and L.F.P.S. Glasg., on August 18th there has been removed from the profession one of the most experienced practitioners of the generation now gradually disappearing from view. For nearly 40 years Dr. Kelly conducted an extensive practice among patients of all ranks and classes, and by his skill no less than by his genuine kindliness of heart won the affection and confidence of a larger circle than it is given to most men to command. His busy life did not exclude a practical part in the general interests of the profession, as is shown by the fact that Dr. Kelly was elected by his brethren to offices of honour and trust in the Faculty of Physicians and Surgeons and to a seat at the board of Anderson's College Medical School. The tribute of regard and respect which is paid to his memory must needs include a word of admiration for the courage with which some 20 years ago he faced a serious financial position due to a disastrous bank failure. But this, indeed, was the man—gentleness with strength.

August 28th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Prison Statistics in Ireland.

THE twenty-third annual report of the General Prisons Board in Ireland, which is dated July, 1901, has just been issued in the form of a blue-book. The number of criminal prisoners committed to the local prisons during the year with which the report deals was 32,924, the daily average number in custody being 2393. Compared with the previous year these figures show a reduction of 3198 in the number of committals and of 221 in the daily average in custody. There were also 58 committals to local prisons under civil process. As in past years the sentences on local prisoners have for the most part been for very short terms, those of one week or less amounting to 42 per cent. of the total number of committals. Under the heading of juveniles, which include all prisoners below the age of 16 years, 309 committals are mentioned, this number being a small increase over any of the totals for the past five years. The report shows a considerable increase in the number of naval and military prisoners, a state of things which is no doubt due to an increase in the number of miscellaneous troops under arms and the extensive scale on which the naval manœuvres were carried out. Under the Inebriates Act of 1898 a State reformatory was opened at Ennis in June, 1899, part of the county Clare prison having been altered for this purpose. The board's report on the institution shows that during the year which ended on March 31st, 1901, six male and 10 female habitual drunkards were admitted to the reformatory under the care of Dr. George Faris, the medical officer, whose interest in the work is specially noticed. Of this number one male patient has been discharged in consequence of ill-health, one female has been certified insane, and one female has terminated her period of detention.

The Meat Traders on Tuberculosis.

Under the somewhat novel heading, "Decrease of Tuberculosis," the *Irish Times* of August 27th conta[illegible] ing communication f[illegible] of his contention a[illegible] British Congress on [illegible] decreasing although the consumption of meat was increasing. In reference to the decrease of tuberculous disease in man he quotes Dr. Arthur Ransome's "Researches on Tuberculosis," 1867-1895: "Grouping all forms of tuberculosis together it may be concluded that an enormous decrease in the disease has taken place; a decrease that means the saving of at least 75,000 lives every year in the present population of England and Wales—three-quarters of a million persons within the last decade." As to the increase in the consumption of meat, he quotes from the Board of Agriculture returns, 1898: "That the consumption of meat per head of population in the period 1876-80 averaged 112 pounds." From the same official returns for 1897 it appears that the consumption of meat per head of population had increased to 131 pounds. Mr. Field states that the meat traders—of whom he is a representative one—desire scientific inquiry, believing that it will prove their contention that localised animal tuberculosis is not communicable to man through the medium of cooked meat. He states, moreover, that they earnestly protest against the confiscation and destruction of sound food and the enormous injury caused to the animal industry of the three kingdoms by measures which are really unnecessary to the preservation of the public health.

Nurses at the Belfast Workhouse.

A long discussion took place at the weekly meeting of the Belfast Board of Guardians on August 20th on the subject of the nurses in the workhouse. It came out in the debate that among the probationers resignations were numerous and it was suggested that it was due either to the fact that everything was not made as comfortable for the nurses as might be, or that nurses after being trained left for more remunerative engagements. It was decided that the infirmary committee should be asked to inquire into the whole matter. It was stated that eight of the nurses were suffering from typhoid fever.

The Belfast Lunatic Asylum.

From the annual report of Dr. W. Graham, resident medical superintendent of the Belfast Lunatic Asylum, for the year ended Dec. 31st, 1900, it appears that there were in the asylum on Dec 31st, 1899, 499 males and 408 females, making a total of 907, while during the year 1900 there were admitted 198 males and 181 females, making a total of 379 admitted. As a result 697 males and 589 females, a total of 1286, were under treatment. 124 persons were discharged and 71 died. The unusual number of admissions (379) is due, to a considerable extent, to the transference of 188 cases from the Belfast Workhouse, the largest number ever received from that institution. There is no doubt that 379 admissions show that insanity is not on the decline as it is an increase of 50 per annum out of a population of 350,000. Dr. Graham wisely combats the view that it should in a pessimistic vein be said that nothing can be done as all this increase is due to heredity; he shows that heredity only means that men are born with a tendency to this or that disorder, and that, under proper conditions, in many instances such tendencies may remain only such and never become actualities. It is from a study of the "proper conditions" that the most fruitful results in the reduction of lunacy may be fairly anticipated. Our duty is to let the people know what are the physiological laws which govern and regulate health so that those with a predisposition to insanity may so order their lives that their nervous system may be better fitted to resist the invasions from without, or the development from within, of those toxins which frequently give rise to mental aberration. It is in this connexion worth noting that the increase in the number of insane persons obtains not among the upper and upper half of the middle classes, but mainly in the ranks of the poorest and most uneducated of the people; hence, Dr. Graham thinks it may be assumed that the bulk of mental derangement is due to neglect or violation of fundamental hygienic laws. He is afraid that among the working classes higher wages and shorter hours mean only increased facilities for self-indulgence, as there is not the slightest proof that the improvement in the prospects of the lower classes has led to a greater degree of self-control. Reference is also made in the report to the great event in the history of the asylum of the past year—the acceptance by the committee of the principles of the villa colony system, which is a great step in advance. The gross expenditure for the financial year was £23,371 5*s.* 6*d.*, being a capitation cost of £24 18*s.* 5*d.*, or an increase of 15*s.* 1*d.* on the preceding year; this slightly increased cost being due to the higher prices paid for fuel and provisions.

The Royal Victoria Hospital, Belfast.

At a meeting of the construction committee of this hospital, held on August 23rd, the architect made the gratifying announcement that the builder was making such satisfactory progress, and was so far ahead of his time-limit—a most unusual circumstance—that it was probable that in another year the new hospital might be ready. It is now quite possible to get a fair idea—the building having proceeded so far—of the anatomy and proportions of the new hospital, and those who have taken a deep interest in the matter feel that the Royal Victoria Hospital, in its structure as well as in the manner of its heating, lighting, and ventilation, will be unique, and will exercise a marked influence in the future construction of such institutions. It is rumoured that the King will come over early next year to fulfil his previous engagement in connexion with the hospital which was abandoned owing to the lamented death of Queen Victoria, to whom the present building is being erected as a memorial.

Poisoning by Sulphate of Copper.

Toxicologists will have to note that there is another risk of poisoning by sulphate of copper than those hitherto commonly recognised, and that is through the spraying of potatoes to prevent "potato blight." It appears from the evidence given at an inquest held in Ballymena on August 23rd that a farm-labourer, named James Gordon, was working on the farm of Mr. G. T. Graham, J.P., Ballee, Ballymena, on August 19th and 20th. He had a spraying machine strapped on his back and was spraying potatoes. On the 19th he complained before dinner of being sick; on the 20th he went home, partook of some supper (potatoes) at 7 o'clock, and retired to rest between 9 and 10 o'clock. In the early morning he was taken severely ill and Mr. Alexander Duncan of Ballymena, who saw him at 4.30 A.M. on the morning of the 21st, found him suffering from severe cramps all through his limbs and body, his heart failing, and his body covered with free perspiration. He died at about two o'clock in the afternoon of the 21st. He had a fresh wound on his hand which was perfectly blue with the "bluestone" which was chiefly sulphate of copper. Mr. Duncan said that if there were scratches on the hands of the person engaged in spraying potatoes, or if the person inhaled the spray, it might possibly produce the collapse. His evidence was that deceased had died from collapse following irritant poisoning. Dr. A. McN. D'Evelyn of Ballymena, who also saw the deceased, agreed with Mr. Duncan as to the cause of death, and said that to take food without washing the hands after being engaged with a spraying machine was extremely dangerous, and he believed, as it was a hot day, that in breathing in the fine vapour of the spray a considerable quantity of poison might have been absorbed. The jury, after recording that the deceased died "from collapse following upon irritant poison," possibly through the absorption of the mixture, sulphate of copper, used in the spraying machine which he carried and used on August 19th and 21st, added a rider that the evidence brought out by Mr. Duncan and Dr. D'Evelyn ought to be a warning to farmers and farm-servants not to engage in spraying potatoes with lacerated hands, or to blow down the pipe of a sprayer, or to take food without washing their hands thoroughly, as any of these practices is extremely dangerous, the bluestone used being an irritant poison. It is possible that the wearing of gloves or long gauntlets and a respirator might be a useful preventive.

Public Baths for Cork.

Owing to the sewage of the city being conveyed into the river lovers of swimming in Cork have been at a distinct disadvantage, being obliged to travel long distances when they desired to indulge in their healthful recreation. The municipality recently decided to rectify this state of affairs, and last week the Mayor officially opened very commodious baths in the centre of the city. One of the baths is free to the public and for use of the other a small fee is charged. All persons, preparatory to entering the swimming baths, are obliged to have a thorough wash in smaller baths specially set aside for the purpose. On the opening day swimming contests were organised by the officials of the corporation. Prizes were offered and there were several competitors. With a view to encouraging large numbers to use the baths it is proposed to hold similar contests periodically. It is pleasant to be able to record that on the second day as many as 2000 swimmers actually availed themselves of the opportunity and the attendants were kept unremittingly busy from early morning till night. A row of coloured tiles is arranged at the bottom of each bath to serve as a guide to divers, and, indeed, the city fathers are to be congratulated on having spared no expense in making the baths complete in every detail. The Mayor has made the very satisfactory statement that the fees received will not only cover all establishment charges, but will also pay the interest on the capital expended, while he points out that above all considerations of the kind are the immense advantages that must accrue to the health of the citizens at large.

August 27th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Dr. Calmette Bitten by One of his Snakes.

DR. CALMETTE, the director of the Pasteur Institute at Lille, has, as everyone knows, discovered a curative serum for the effects of snake-bite. This serum he prepares with his own hands in his own laboratory by immunising animals with successive doses of snake-venom. He was only the other day severely bitten by a trigonocephalus. This, however, was not due to any carelessness upon his part, for he takes every precaution in collecting the venom and has invented a kind of forceps which he introduces into the cage and with which he seizes the head of the snake so that it cannot escape. The cage is then opened and the snake being forced to open its mouth the venom, which appears in drops at the points of the fangs, is collected in a Pravaz syringe. Despite all precaution the forceps must have slipped, for Dr. Calmette was severely bitten on the right hand, and the venom of the trigonocephalus is extraordinarily rapid in its action. Dr. Calmette without delay gave himself an injection of his anti-venomous serum, but nevertheless the hand swelled up and acute fever set in; but by the afternoon of the same day Dr. Calmette was sufficiently recovered to attend a sitting of the Conseil-Général of the Department, at which he argued in favour of a grant in aid of the sanatorium which he has undertaken to found at Lille. On the following day he was perfectly well, having thus afforded in his own person, albeit unwillingly, a convincing proof of the efficacy of his excellent remedy.

A New Microbe Discovered in Dysenteric Patients.

Dr. Lesage of the Pasteur Institute has just announced that he has noted the presence of a new microbe in the blood of patients suffering from dysentery, a large number of whom he has had the opportunity of observing at the Saint-Mandrier Hospital at Toulon. The patients examined were cases of dysentery from China, Cochin China, Algeria, and a local form of the disease. The micro-organism appeared with great regularity, its number increasing as the disease progressed and diminishing with the return to convalescence. Without actually calling the microbe specific, it can at least be said that its development has a definite relation to that of dysentery and to that alone. It is very polymorphic, sometimes appearing as a micrococcus, sometimes as a streptococcus, but more often as a diplococcus, of which one portion is much smaller than the other. Dr. Lesage compares its appearance to that of a balloon with the car attached. The diplococcus is motile, shining, and surrounded by a white capsule which often contains many diplococci. It stains badly, is decolourised by Gram's method, and grows well in liquid culture media. On gelose it forms indefinite cultures having the aspect of a granular veil. It does not coagulate milk. In the living body it is found plentifully in the various intestinal discharges of dysentery, such as the mucous débris of the stools, and also in dysenteric sputum. On post-mortem examination it is found in all organs but most of all in pure cultures of the mesenteric nervous system and in the swollen mesenteric glands. It is also found in the ulcerated intestinal mesentery. Cultures injected under the skin of a rabbit or of a guinea-pig bring about fatal septicæmia without, however, any intestinal localisation. In the cat there is not only septicæmia but a definite localisation in the large intestine which shows exactly the same clinical appearances as occur in man, such as congestion of the mucous membrane. Dr. Lesage is about to publish a further communication containing more details. This should be of great importance considering how competent is the observer and the special knowledge which he possesses of the bacterial flora of the intestine.

Medical Heroism.

The announcement recently made by Professor Koch at the British Congress on Tuberculosis that bovine tuberculosis is not transmissible to man has not only been the means of evoking much surprise, but has also been the cause of sundry medical men offering themselves as subjects for an experiment with regard to a question which affects in the most marked manner the social hygiene of the whole human race. From Paris Dr. Garnault has written a letter placing himself at the disposition of Professor Koch for the purpose of experiment. At present Dr. Garnault has received no answer. In his letter he stated that he was 41 years of age, that he weighed over 100 kilogrammes, that his height was one metre 81 centimetres, and that his health was perfect. He added that he had no children and that he was anxious to submit himself for a tuberculosis experiment. In his opinion it was only natural that medical men should be willing to sacrifice themselves in such a cause for in wars men of far inferior education and mental capacity offer themselves by thousands in a much less noble cause. Although the lay press has nothing but praise for Dr. Garnault's heroic offer the medical press is more sceptical. Putting aside the fact that Professor Koch is not in the least likely to accept the responsibility of such a risky experiment—one moreover, which anyone has the right to make for himself without involving the German professor in the matter—the medical press in general points out that the sacrifice would be useless and would prove nothing. Dr. Garnault or any other person who tried the experiment might be refractory to tubercle, a reason which would be sure to be given if the subject of the experiment survived, while if he were to succumb plenty of people would say that he had contracted tubercle in some other method than by the inoculation. Some of the papers have revived the old idea of making the experiment upon criminals condemned to death, as did Ambroise Paré for his first operation of cutting into the bladder. That such an idea should have been formulated has, in my opinion, one good point—namely, that it will impress the public in a forcible manner, far more than any conference or pamphlet, with the importance of hygienic measures as a method for the prevention of tuberculosis.

August 27th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Serum Treatment of Tetanus.

AT a recent meeting of the Verein für Innere Medicin Professor Leyden showed a patient who had suffered from tetanus but who had been successfully treated by injections of Behring's antitoxin. The case was remarkable from the fact that the antitoxin was injected into the subarachnoid cavity of the spine. The patient was a stableman, 22 years of age, who had shown symptoms of trismus and tetanus for three days. Immediately after his admission into the Charité Hospital his spinal canal was punctured, 10 cubic centimetres of fluid were withdrawn and five cubic centimetres of antitoxin were injected. A similar amount was injected three days subsequently. After the injection the patient's temperature which had been 41° C. (105·8° F.) decreased on the same day to 38·5° C. and on the next day to 37·4° C. (99·4° F.). Previously to the administration of the antitoxin a subcutaneous injection of morphia was given and hydrate of chloral was administered afterwards. Professor Leyden said that according to his experience cases of tetanus in which the temperature rose to 41° C. were always fatal and that the rapid decrease of the temperature after the injection and the ultimate recovery of the patient were therefore due to the antitoxin. Another remarkable feature of the case was that there was no trace of a wound by which the infection might have been introduced. It is known however that horsedung contains tetanus bacilli and the patient being a stableman might possibly have contracted the disease by inhalation. The sputum was therefore examined microscopically, but the result was negative. Mice inoculated with the sputum showed no ill effects but after inoculation with the patient's spinal fluid they suffered from tetanus.

The "Practical Year" of the Medical Curriculum.

The new regulations relative to the State examination qualifying for medical practice provide that candidates after having passed the examination shall spend a year in practical work at a hospital or similar institution as a "practicant" and that diplomas shall not be granted until the "practical year" has been completed. The Minister of Public Instruction has recently ordered that only hospitals with at least 50 beds shall be privileged to receive practicants so that each practicant may have 25 beds. They will have to work not only in general hospitals but also in lying-in hospitals, in lunatic asylums, in hospitals for diseases and injuries of the eye, in children's hospitals, and in sanatoria for phthisical patients but not in hospitals or asylums for incurables. A portion of the practical year may be spent not in an hospital but in an institution where some department of medical science can be studied, such as in an anatomical or physiological laboratory, or in the dissecting room of a university or public hospital. The hospitals and institutions which receive practicants will be registered by the Government and a list of them will be published for the information of candidates.

Gonorrhœa in a Children's Hospital.

A sad state of matters has recently formed the subject of an article in a Berlin daily newspaper. It appears that in the Elizabeth Hospital for Children some of the patients are infected with gonorrhœa and that new cases have occurred within the last few days. The infection is said to have been introduced a year ago by three children suffering from internal complaints in whom the presence of gonorrhœa was not recognised at the time of admission. The disease spread notwithstanding the prophylactic measures adopted by the medical staff and within a year more than 40 children became infected. The announcement of these facts has created a sensation and in the newspapers the nurses, who belong to a religious corporation, are accused of inattention to cleanliness. The matron in an interview with a reporter said that the conditions which exist in some working-class families must be held responsible for the calamity which has taken place. She added that a good many children suffering from diseases of that description were admitted but that until now no case of infection of other children within the hospital had happened during the 27 previous years of its existence. The medical officer of health has inquired into the circumstances but it does not appear that he has found any responsible person to be at fault.

August 26th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Annual Meeting of the Executive Health Officers of Ontario.

THE annual meeting of the Executive Health Officers of Ontario was held on June 25th and 26th in the city of Brantford, Ontario, under the presidency of Dr. W. T. Connell, pathologist of Queen's University, Kingston. An important discussion took place on small-pox and a number of representative physicians from different parts of the province united in testifying from their experience and observation that thousands of cases of so-called vaccination were utterly worthless as protection against the disease. The causes which can be ascribed to this are careless handling and administration by medical men, careless transportation by railways, but chiefly the desire of the manufacturers to carry the refining too far and, as one delegate put it, to sacrifice the practical for the scientific or commercial side of it. After a lengthy discussion the meeting appointed a special committee to look into the question and to report at the next annual meeting. In his annual address the president referred to the question of unsuccessful vaccination, stating that after investigating 5000 cases in and around Kingston, where the vaccine was supplied by practically only two firms, the results produced were exceedingly anomalous. Dr. Connell argued for the establishment of county laboratories and county medical health officers. Another important question which was fully discussed was the establishment of county sanatoria for the treatment of consumptives and an influential committee was appointed, one member from each county in the province, to look after the question of having by-laws submitted to the people for the establishment of these institutions. Dr. J. I. Kitchen of St. George was elected President and Mr. Thomas Macfarlane, chief dominion analyst, Ottawa, vice-president, Dr. P. H. Bryce being re-elected secretary.

Barbers' Association of the Province of Quebec.

In 1899 an Act was passed by the local legislature incorporating the Barbers' Association of the Province of Quebec which stipulated that every practising barber should become a member of the association and should submit to medical inspection of their shops and person with a view to prevent the spread of certain diseases and also to promote cleanliness and other sanitary conditions. At first the proposal was cordially received but now there seems to be no end of trouble over the interpretation of the association

Finally, after a trial of three years, a petition has been circulated requesting the Lieutenant-Governor to revoke certain sections of the Act which are said to bear heavily upon the journeymen barbers. The reformers declare that the so-called hygienic precautions are unnecessary, as cleanliness constitutes the only one to which the barbers can be restricted, and that the pretended medical examination has been a mere farce and was only designed for the purpose of extracting another $2 fee from the barber so examined. They consider that the barber so examined by a medical man may become contaminated from one moment to another, and to make such examination really useful and serious it would be necessary to examine the barber after each operation, which they deem utterly impracticable.

Anthrax in Eastern Ontario.

Recent reports received by the Department of Agriculture at Ottawa show that anthrax has broken out at several points in the province of Ontario. The disease is at yet confined to cattle and some horses, many of the former and some few of the latter having died from the disease, but fears are entertained that it may spread to human beings on account of the foolhardiness of a farmer who, contrary to the warnings of the local veterinary surgeon, sent hides from the dead cattle to a tannery near by, the employés of which are now under strict surveillance. Considerable difficulty has also been experienced in obtaining anthrax vaccine from the Pasteur Institute in Chicago, but that difficulty has at last been overcome and the Department of Agriculture is now in possession of a plentiful supply to cope with the outbreak.

Sanitary Regulations for Ontario Lumber Camps.

After the experience with which the provincial board of health of Ontario has had to contend for the past eight months in the northern portions of the province in checking an unusual epidemic of small-pox, the Ontario Government has deemed it prudent to adopt special regulations of a sanitary character, with a view to safeguarding the health of employés of such places as lumber camps, saw-mills, mining camps, railway construction camps, smelting works, &c. There are over 400 unorganised townships in the northern part of Ontario, stretching from the Ottawa river on the east to the province of Manitoba on the west, a distance of 1200 miles, a section which contains over 100,000 people; and it is especially for the safety of the health of these people that the Government has thought fit to provide for outbreaks of contagious diseases and for the hygienic conditions of camps, works, &c. The regulations will seek to hold the owners, managers, or foremen responsible, and these or the medical officer present will have to report direct to Toronto should small-pox or any other contagious disease appear in their midst.

Ottawa Contagious Diseases Hospital.

For some years now Ottawa has been struggling to establish a proper hospital for the reception of persons who are the subjects of contagious or infectious diseases, but up to the present time these efforts have proved ineffectual. A cottage hospital was erected in the Rideau river several years ago, but on account of there being a liability to inundation from spring freshets, the site was condemned by the provincial health authorities and ever since Ottawa has been seeking a new and more appropriate site. A site was chosen adjoining the residence of Lord Minto, the Governor-General, but his lordship would not hear of such a thing, so a new site was selected on the high sandy banks of the Rideau, in the rear of the Protestant General Hospital; and the city council is said to have agreed to pay $31,000 for it, although the price is double the assessed value of the property. The mayor of the city has ordered an investigation. An important judgment has just been given by Judge McTavish which establishes the 150-yard limit from any residence. In the meantime the city has more than its share of contagious diseases and an inadequate means of providing isolation.

Deaths in Maternity Homes in Toronto.

A mortality of 50 per cent. in a maternity home just beyond the northern outskirts of Toronto has recently been causing considerable comment. It is not under the jurisdiction of the civic health department, but the death-rate has been deemed so excessive as to merit an investigation into the causes thereof. In the city proper there are 15 maternity homes, which for the past two or three years have been directly placed under the special supervision of a medical man who reports to the medical health officer. There are also 35 baby farms which are all subjected to very close inspection and a careful record is kept. The infants born in the maternity homes of Toronto last year numbered 130. Of these 14 died, 13 were adopted into good homes, three were reclaimed by, and the same number were forsaken by, the mothers, and the rest remained in the homes.

August 19th.

Obituary.

JULIUS ST. THOMAS CLARKE, M.D., M.S. Lond., F.R.C.S. Eng.,

SENIOR SURGEON TO THE LEICESTER INFIRMARY.

By the death of Dr. Clarke Leicester loses one of its oldest medical practitioners, he having been in practice there for nearly 40 years. He started his medical education at Guy's Hospital, where he had a very brilliant record, taking the exhibition and gold medal in anatomy and the gold medal in physiology at the University of London in 1861, and also the treasurer's gold medal of Guy's Hospital in clinical surgery. He started practice in Leicester and in the earlier years was medical officer to the workhouse, but on a vacancy occurring on the infirmary staff he abandoned this work for the post of surgeon to that institution, which he held up to the time of his death, then being senior surgeon. Besides his connexion with the infirmary Dr. Clarke was honorary medical officer to the Institution for the Blind, and was most warmly interested in the work. He was a keen advocate and worker for the temperance cause and had been himself a total abstainer for the greater part of his life; in fact, his whole life was one of great asceticism, luxury of any sort being completely foreign to his nature, while those who knew him best knew also that a single-minded devotion to duty was the keystone of his life. He was also much interested in, and successful with, treatment of patients suffering from the effects of abuse of drugs and was medical officer to Tower House, Leicester, for 27 years. All through his life his great desire was to keep well abreast of the medical knowledge of the day, and as a proof of his energy and indomitable will power it may be mentioned that he took both parts of the Fellowship of the Royal College of Surgeons of England while engaged in a very arduous practice and also that he took the degree of M.D. London only nine years ago at the age of 55 years, and that of M.S. two years later. Although with advancing years his health was not so good as formerly, the outrage which befel him last October—that of being shot through the sacrum by a former patient who had been confined in an asylum on account of homicidal tendencies—rendered his physical condition much weakened, but nevertheless his will-power carried him through eight months' work, when he took a holiday in Scotland but only to return at the end of 10 days on account of attacks of syncope. He was able to go out till the day before his death which occurred during his sleep on August 2nd at the age of 64 years. The only wish ever expressed, and that at the time of his accident, was that he should be taken once again to the infirmary he loved so well, and this was able to be fulfilled as the first part of the funeral service was held in the chapel of that institution, the interment taking place in the Leicester Cemetery on August 6th. The motto of his life, often quoted and always acted up to, was:—

"When I sought Happiness she fled
Before me constantly;
Weary, I turned to Duty's path
And Happiness sought me."

DAVID FRANCIS SITWELL CAHILL, M.D., L.R.C.S. Edin.

By the death of Dr. Cahill Berwick-on-Tweed loses one of its oldest and most respected practitioners. He was the son of the late Surgeon-Major Cahill of the 25th Regiment of Foot and received his medical education at Edinburgh and Paris. In 1845 he obtained the degree of Doctor of Medicine of the Edinburgh University, and in the following year became a Licentiate of the Royal College of Surgeons of Edinburgh. For 50 years he carried on an extensive practice in the

Border districts and in May, 1896 celebrated his jubilee as a practitioner He then retired from active medical work. Dr Cahill was a member of the Berwick Naturalist Club and was first senior physician and surgeon and subsequently consulting physician to the Berwick Dispensary The deceased gentleman, it is alleged was assaulted some time ago and he was recovering from the injuries he then received when an attack of influenza brought about his death on August 18th He leaves a widow and grown up son and daughter

---

DEATHS OF EMINENT FOREIGN MEDICAL MEN —The deaths of the following eminent foreign medical men are announced —Dr Nath of Königsberg, an active hygienist who took great interest in the training of midwives , Dr Hermann von Widerhofer, professor of Children's Diseases in the University of Vienna and Body Physician to the Imperial Family His most notable published papers dealt with abdominal and glandular diseases in childhood and with questions in heredity —Dr Ernst Braun, formerly director of the Lower Austrian Foundling and Lying in Hospitals —Dr Hameau, vice president of the Medical Association of France —Dr Tordeus professor *agrégé* in the medical faculty of the University of Brussels —Dr Maisch formerly professor of materia medica in the Medico Chirurgical College, Philadelphia

Medical News.

SOCIETY OF APOTHECARIES OF LONDON —In August 1901 the following candidates passed in the subjects indicated —

Surgery —J C Baggs (Section II) St Thomas's and Westminster Hospitals P C Burgess (Section II) Middlesex Hospital D Fletcher St Bartholomew's Hospital, F I M Jupe Cambridge G J W Kelgwin (Sections I and II) London Hospital E R Risien (Section II) St Batholomew's Hospital W B Skelton, Guy's Hospital and M J Williams St Bartholomew's Hospital

Medicine —J W W Adamson (Section I) St G[illegible] J H Beasley (Section [illegible] University College Hos[illegible] St Mary's Hospital [illegible] D J Morgan (Section [illegible] [illegible] J T Longhurst St [illegible] Hospital; E Osborne [illegible] A W D Thomson St George's Hospital, P P Tollit King's College Hospital and S C Wilkinson Leeds [illegible] T S Davies [illegible] E S Perkins [illegible] and St Mary's [illegible] Young, Leeds

The diploma of the Society [illegible]

FOREIGN UNIVERSITY INTELLIGENCE —*Berlin* An institute of state medicine is about to be established.—*Bologna* Dr Novi, Extraordinary Professor of Experimental Pharmacology, has been promoted to the Ordinary Professorship —*Heidelberg* Dr Gaupp has been recognised as *privat docent* of Gynæcology The Senate has directed that foreigners can only be admitted as medical students when they can show that they have passed an examination in general knowledge equivalent to the German *Abiturienten Examen* —*Leipsic* Dr H Füth has been recognised as *privat docent* of Gynæcology —*Rostock* Dr W Müller of Aix la Chapelle formerly assistant to Professor König in Berlin, has been appointed to the chair of Surgery vacated by Dr Graser who is migrating to Erlangen.—*Tubingen* Dr A. Dietrich has been recognised as *privat docent* of Pathological Anatomy

BEQUESTS TO HOSPITALS — The late Mr R Bowerman West of Exeter has bequeathed £4000 each to the Royal Devon and Exeter Hospital and West of England Eye Infirmary Exeter , £1000 each to the Exeter Dental Hospital Exeter Dispensary, Ockenton Convalescent Home, Western Counties Idiot Asylum and the Taunton and Somerset Hospital , and £500 each to the Ottery St Mary Cottage Hospital and the Axminster Cottage Hospital

NATIONAL SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN —Mr Peregrine Purvis has given a donation of £1000 to this institution

ADDED WATER IN BUTTER —At the Cheltenham Police court on August 22nd certain butter merchants were fined £20 for selling butter containing 6·2 per cent of added water It was stated that this firm had been previously convicted six times within a few months, the fines being either £50 or £20

POOR-LAW PATIENTS AT THE SEASIDE —At the meeting of the Merthyr Tydvil Board of Guardians held on August 17th it was mentioned that the guardians proposed to send convalescent patients from the workhouse to the seaside, the Local Government Board having written stating that if the medical officer of the workhouse was of opinion that a visit to the country or seaside was necessary for the health of any individual inmate, and if he certified accordingly the assent of the Local Government Board to the expenditure would not be required.

NORTH DEVON INFIRMARY, BARNSTAPLE —The seventy fifth annual meeting of the friends of, and subscribers to, this institution was held on August 20th The report stated that during 1900 there were 640 in-patients admitted and 2756 out patients treated, as compared with 651 in patients and 2710 out-patients in 1899 The financial statement showed that the expenditure amounted to £2779 and the income to £2405 The committee allude to the good work of the convalescent home at Morthoe which is in connexion with the infirmary

KENT BENEVOLENT MEDICAL SOCIETY.—The annual meeting of the members of the above society was held on July 17th at Maidstone, under the presidency of Dr C E Hoar The accounts for the year ending July 5th last were laid before the meeting after being duly audited, and as it appeared that a balance of £415 might probably be anticipated for the coming year it was resolved that a sum of £100 should be added to the invested capital of the society and that the sum of £255 should be distributed amongst the several applicants for assistance whose names were then before the meeting The society, which was instituted in the year 1787, has been the means of benefiting the widows and orphans of its members (and in some cases the members themselves) and thus has relieved distress in the families of those who had long and honourably laboured in the medical profession For several years past the society has been enabled to distribute annually a sum of about £300 towards the relief of deserving cases, and the fact that the society now has an invested capital of £9500 is a guarantee that the good work which has been carried out in the past will be continued The secretaries of the society are Dr C E Hoar of Maidstone Mr H G Sadler of Canterbury, and Dr H C Burton of Lee and the assistant secretary is Mr James Wiltshire of the Bank Canterbury, and they will be pleased to furnish any further particulars which may be desired.

THE LATE MR W H F RAMSDEN —In memory of the late Mr Ramsden the inhabitants of Saddleworth have subscribed for the erection of a handsome public monument and drinking fountain at Dobcross. The members of the district council and a large gathering, amongst whom were three sons of the late Mr Ramsden, themselves medical men witnessed the unveiling ceremony, which was performed by Miss Brierley of Denshaw on August 24th In formally handing the monument over to the care of the district council the Rev H P Edwards said that they were met together on a unique occasion The memorial was the result of a spontaneous outburst of feeling in Saddleworth when the news came of the sudden decease of Mr Ramsden and was a testimony of the great affection in which he was held The Rev Charles Ramsden said that it was a matter of great pride and gratification to the family that the people of Saddleworth had been so determined that his father's memory should not be allowed to die out from amongst their hills and valleys The Rev W T John said that gratitude was not dead and that those of the present generation needed no memorial to remind them that Mr Ramsden had lived amongst them. Future generations would however be reminded of one whose determination was to do his duty and would be encouraged to go and do likewise. The monument is of polished Aberdeen granite, bears a gas lamp and is by the kindness of the corporations of Ashton Stalybridge, and Dukinfield, provided with water for man and beast free and for ever. On the column is the inscription: "W. H. F. Ramsden, Physician and Surgeon, for 24 years Medical Officer of Health to the District. Born 1833. Died 1900. Erected 1901 by public subscription to commemorate his devoted services to the people of Saddleworth. 'Write me as one that loves his fellowmen'"

[illegible] road, W.—House Physician [illegible] board and lodging provided. [illegible] Surgeon. Salary £70 per annum, with rooms, board, and washing.

Births, Marriages, and Deaths.

BIRTHS

BOXALL.—On August 26th, at Portland place, W., the wife of Robert [illegible]

[illegible] Lond., of a daughter.

WALLACE.—On August 25th, at Battersea rise, S.W., the wife of Joseph B. Wallace, M.B. Glasg., of a son.

MARRIAGES

NEWSOME—GIBBS.—[illegible] by the Rev. C. [illegible] B.S. Durh., late [illegible] of William Gibbs, [illegible]

SULLIVAN—DUNCAN.—On August 27th, at St. Katharine's Roman Catholic Church, Bow, P. Sullivan, L.R.C.P., L.R.C.S., &c., of Campbell road, Bow, to Janet Blanthorne, younger daughter of Captain Robert Duncan, of the R.M.S. *Kinfauns Castle*, and of Forest Gate.

TAGGART—COCLOUGH.—On [illegible] Greenheys, Manchester, [illegible] Taggart, M.B., Ch.B. V[illegible] late Cæsar Scott Tagg[illegible] Mrs. Coclough, Burslem, Staffs.

SILVER WEDDING.

HAYNES—JONES.—On August 30th, 1876, by the Rev. C. Musgrave Harvey, rector, the Rev. A. B. Dickinson, rector of Old Radnor, and the Rev. Alfred Scott, Horace Eyre Haynes, of Evesham, to Lucy Marion, second daughter of Frederick Jones, Esq., of The Friars, Acton (now residing at Blainpstone House, Bedford).

DEATHS

BAK[illegible] ing Baker, M.R.C.S. [illegible] Service, retired.

BIR[illegible] Kensington, Henry [illegible] M.B., M.S. Aberd., J.P., aged 57 years.

KELLY.—Suddenly, on August 12th, Adam Lawson Kelly, M.D., L.F.P.S. Glasg., aged 66 years, of 26 Blythswood square, Glasgow.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A DISPUTED ACCOUNT.

THE *Windsor Chronicle* of August 23rd contains an account of an action brought by Mr. W. L. T. Goodridge, a medical man at Windsor, against Mr. A. F. Davies, landlord of the Grapes Hotel, in the same town, for the sum of £1 13s. alleged to be due for professional services. The action began in a manner that is very *familiar to medical men. One guinea of the account was for attendance* upon the defendant's barmaid, and the question arose whether the defendant, or *the patient*, or *the patient's mother was liable for* this sum. The other 12s. was charged by Mr. Goodridge for attendance upon Mrs. Davies's baby. According to Mr. Davies, the visits to the baby were not professional visits but friendly ones, mere casual conversations when Mr. Goodridge was in the house, and he also maintained that he was not liable to pay the barmaid's account, although it would seem that he or his wife called Mr. Goodridge to attend upon her. We are glad to say that the judge gave judgment in favour of Mr. Goodridge for the full amount claimed, with costs. But winning his case in a county court will hardly compensate Mr. Goodridge for the annoyance which he has had to undergo. A public-house is a centre of gossip, and the defendant's view of the matter was certain to be insisted upon before the action and will probably be stated frequently now that the case has gone against him.

WANTED—A SEASIDE RESORT.

To the Editors of THE LANCET.

SIRS,—Can you or any of your readers give me the name of a quiet seaside town on the south-west coast where a person suffering from catarrhal phthisis could pass the winter with a minimum of cold and wet weather? The patient, a lady, has benefited materially by open-air treatment for the last two months and has an insuperable objection to going abroad for the winter. One lung only is affected and that not seriously. *I am, Sirs, yours faithfully,*

August 20th, 1901. OPEN-AIR.

DIVISIONAL POLICE SURGEONS AND CABMEN.

WE have received a copy of the *Cab Trade Record*, the official journal of the London Cabdrivers' Trade Union, for August, 1901. The London cabby is, as a rule, a civil-spoken, hard-working man. He may have his own interpretation of the Scriptural dictum: "Whosoever shall compel thee to go one mile go with him twain," but we prefer to regard his fondness for making two miles into four as a weakness *rather than a vice. The interests of cabmen will not be served by* such impertinences as appear in the official journal which has been forwarded to us, in passages marked on pages 2 and 4. The paragraphs in question deliberately charge "some of those medical hacks known as divisional police surgeons" with being "in with the police" and with doing their work in a "perfunctory and self-interested manner." A more graceless, baseless charge was never brought. The *Cab Trade Record* insists that every cabman charged with drunkenness should demand to be examined by an independent medical man. We see no objection to any cabman calling in as many medical men as he likes, provided that he pay them their fees, but we see every objection to the bringing of unfounded charges against a set of men who are quite as honest and as hard-working as cabmen.

MANDRAKES.

ON August 24th Mr. William Hawkins was charged at Southwark Police-court with being drunk and disorderly. He was hawking mandrake and had established his "pitch" outside the shop of a rival dispenser of drugs whose goods he was comparing with his own much to the depreciation of the former. But as regards Mr. Hawkins and his mandrakes which were probably briony roots, he has only himself to blame for getting into trouble. He mentioned that he dug up his mandrakes with a table knife. This is not at all the right way to go to work. The mandrake, if we may believe experts on the subject, is a terrible root and demands caution. According to the best authorities when evulsed from the earth it is naturally annoyed and shrieks. If the gatherer hears the shrieks he immediately dies or goes mad or is stricken with some loathsome disease. The proper way to gather mandrakes is to go to where they grow at the right time, the season of the year, the phase of the moon, and several other matters being taken into consideration. A dog, preferably one belonging to some one else, also has to be procured. One end of a cord is to be attached to the mandrake and the other to the dog. The seeker after mandrakes *having carefully stopped his ears* says "Rats" or stimulates the dog by whipping it so that it bounds forward and so pulls the mandrake out of the ground. On hearing the shriek the dog dies. The root is then carefully gathered into a clean linen cloth and taken home. The genuine article is the *Mandragora officinalis* and if gathered according to instructions it possesses wonderful properties. The earliest recorded use of mandrakes was as a charm or drug to promote fertility, as may be seen from Genesis xxx. 14. But as mandrakes were uncommon and dangerous to get and there was a great demand for them the ingenious traders were wont to substitute artificial mandrakes. Sir Thomas Browne gives the following description of these mandrakes quoted from a physician named Mathiolus who he says learned this "way of Trumpery from a vagabond cheater lying under his care for the French disease. ...... The roots, which are carried about by impostors to deceive unfruitful women, are made of the roots of canes, Brinoy, and other plants, for in these, yet fresh and virent, they carve out the figures of men and women, first sticking therein the grains of barley and millet where they intend the hair should grow; then bury them in sand until the grains shoot forth their roots, which at the longest will happen in 20 days; afterward, clip and trim those tender strings in the likeness of beards and other hairy teguments." We do not wish to imply that this was Mr. Hawkins's method, but we merely point out that he cannot find the genuine mandrake in this country for it does not grow here, and that it is as well for him that he cannot if he digs up his roots with a knife. He was fined 5*s*. and we think he may consider himself lucky that nothing worse happened. Dabbling in magic nowadays does not pay.

"THE EQUIPMENT OF A CIVIL SURGEON AT THE WAR."

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent "Civil Surgeon," in THE LANCET of August 24th, p. 574, I would suggest the subjoined kit for a civil surgeon going to South Africa. Many of the things perhaps seem superfluous, but no one would regret having taken them when once up country. All camp furniture, &c., can be easily disposed of at cost price on leaving the country, so that the initial outlay is not really so great as it seems. Many men, to avoid a little extra expense, take all manner of makeshifts most weird; the position of civil surgeons is anomalous enough in all conscience—they need not look like bandits. Primarily uniform is absolutely essential—there is a local army order to that effect. I would strongly urge that it should be bought at a "pukka" military tailor's, such as [illegible], Piccadilly, and not at any "stores." The following is the list: One khaki serge tunic, one khaki drill or gabardine tunic, both with leather buttons and detachable gorget patches and no badges of rank. I would also suggest a plain blue serge "jumper" with brass buttons and plain blue trousers. This suit would be found to be most useful at mess, dining out, &c. One pair khaki serge trousers, one pair khaki drill trousers, one pair Bedford cord riding breeches strapped with leather, one pair pigskin Stohwasser leggings, one pair khaki Fox's spiral putties, one pair not too heavy brown shooting-boots, one pair lighter weight brown boots, one pair leather slippers, one dozen pairs extra leather laces and boot-cleaning gear, one khaki serge field cap, one good felt slouch hat with puggaree, one Sam Browne belt without sword attachment, one khaki haversack, one Silver's vulcanite water-bottle, one military mackintosh, one cavalry cloak (to be obtained at the Army Clothing Factory, Pimlico), one flannel "mufti" suit and a soft cap, four good flannel shirts, one medium Jaeger vest and pair of pants, two suits flannel pyjamas, 12 pairs socks, two khaki silk handkerchiefs for the neck in lieu of collars, 12 handkerchiefs, one camp bed and mattress, one Wolseley valise, one pillow, two blankets, one canvas bath, and one cavalry aluminium canteen. The camp furniture should be marked with the owner's name in plain letters. One Berkefeld filter, one pair of spurs, and one waistbelt with swivel for attaching a good hunting knife. All the above with the exception of the camp kit can be put into a large waterproof canvas kitbag to be obtained from the Army Equipment Stores in Regent-street. The camp kit and Wolseley valise can be put in a canvas sack with padlock mouth. In addition I should advise the taking of a small-size Gladstone bag for small articles. A supply of chocolate and Lazenby's soup squares are sound things to take, and above all things a Berkefeld filter. If fond of sport a 12-bore shot-gun should be taken, which can be easily sold on coming home, and about 500 cartridges No. 3 and No. 6 shot. A Zeiss field-glass is very useful to have and a camera (No. 3 pocket folding Kodak for choice) and six dozen films in a calcium tube. For instruments a pocket case, a stethoscope, a one-minute clinical thermometer, and a hypodermic syringe with metal piston with a supply of tabloids.

I am, Sirs, yours faithfully,

St. Thomas's Hospital, S.E., August 27th, 1901. A. E. STEVENS.

A DOCTORS' AGE

To the Editors of THE LANCET.

SIRS,—When is he old? When is he so old-fashioned as to be in the eyes of his patients useless? Time was, and not so long ago, when a medical man was not much considered, not much trusted, and not often consulted by the people till he had arrived at a good old age as to time and experience. But we have changed all that now, and the doctor may become old-fashioned, even professionally decrepit, when comparatively young and not yet by any means in the sere and yellow leaf. This terrible fact arises from two apparent causes. Many medical men, once qualified, once endowed with their degrees or diplomas, are so far satisfied with their position that they cease to work, read, or keep up with all the many advances and improvements in the progressive science and art of medicine. Another reason is that medicine, that is, the science and practice of his art, is so progressive that it is no libel to say that the student of to-day knows as much as the profession of 20 years ago, and what was looked upon as truth, founded on stable law, is found by the increased and burning light of scientific research to be doubtful if not fallacious. This being so it comes to this, that unless the practitioner keep pace with this advance he necessarily falls behind in the race and becomes what is called old-fashioned, effete, and, indeed, a drug in the market. Patients—i.e., patients in the higher platform of intelligence—very often come to look with suspicion on the medical man whose hair is white and who, in their idea, has travelled beyond the energies, and maybe the conceits, of youth. The remedy, if there be a remedy, for this untoward state of matters is for the medical man to be as much a student as practitioner, and to show his patients that, though old in years, his age is dowered by the best and most progressive of scientific experience. We are told in the Book that on the walls of Belshazzar's banqueting-hall appeared the words, "*Mene*, he is numbered; *Tekel*, he is weighed"—referring to the impending destruction of Babylon. Let these ominous words, when applied to the old medical man be words denoting that though old in years he may still be young and vigorous, so far as he is concerned with the scientific practice of his pr fession. The physician or surgeon living in cities or towns, whe he has the great and manifest advantages of the hospital or infirmar can, if he likes, rise to, and keep the platform of, the highest and mo enlightened practice. This cannot be gainsaid, but it must not forgotten that as "stone walls" do not a prison make, so the gener practitioner, or even the village doctor, has in his practice (especiall midwifery) as much material for scientific research as the mo fashionable and successful city practitioner. Only, let it be understoo that this general practitioner must keep up to the times, must be th diligent student first, to be the successful and respected practition afterwards.

I am, Sirs, yours faithfully,

August 22nd, 1901. SENEX.

"HOME EXERCISES IN SPINAL CURVATURE."

To the Editors of THE LANCET.

SIRS,—Would you or one of your readers inform me who is th publisher of this book? The price is 2*s*.

I am, Sirs, yours faithfully,

August 25th, 1901. ENIGMA.

"STUPID, ISN'T IT?"

> "No, don't do that. I don't want to be found here. Besides, it useless. I know exactly what has happened. A point of th serrated edge of the Order has pierced the brain near the eye. Th first effect was unconsciousness, the next will be internal bleedin the last will be coma and death. In five minutes a clot of bloo will have covered the lacerated brain, and I shall lose consciousne again. Stupid, isn't it?"

When we happened to see the above passage quoted in sundry review of Mr. Hall Caine's book we were inevitably reminded of certai graphic and obviously inaccurate passages about hospitals whic appeared in "The Christian." When, however, we read the "Etern City" for ourselves we thought it possible that Mr. Hall Caine h compressed as much ignorance on medical subjects as he could in six lines because the drivel is exactly what a man like Bar Bonelli would have said. He was a wicked old man who w false to his mistress and false to his wife, whom he left to d alone, though he had the decency to see her body removed the church. He was, though a Prime Minister, nothing b a *poseur* with an affectation of knowing everything, so that whe he was dying he might very well have made the silly speech p into his mouth. But a further perusal of the book assures us th the speech is not due to Baron Bonelli's overweening vanity but Mr. Hall Caine's ignorance. On page 349 is a description of the la illness of the countess, the aunt of the heroine. Dr. Fedi, th physician called in, came and "examined the countess—her breas her side, and the glands under her arms ...... and announced th the patient must have a nurse immediately." When he ca again he found his patient worse and thus delivered hi self: "Your aunt has internal cancer. If the tumours h been diagnosed while still small nephrectomy might have be possible; now they are beyond the reach of legitimate surger A man who either thinks that malignant disease of the kidn can be diagnosed by examining the mamma and the axillary glan or, else, that nephrectomy is the operation usually performed mammary cancer, will believe anything. The doctrine of invi cible ignorance will, perhaps, be a reason for thinking that Mr. H Caine is not a wilful sinner, but the man who writes on medi subjects in such a fatuous manner is not the one to criticise hospit and their work with the pomposity and self-satisfaction with wh Mr. Hall Caine wrote in "The Christian."

◆

X. Y. Z.—If we understand the question the patient is not only of a now but was of age at the time that he was attended. We think th the decision, if legal proceedings were taken, would depend upon t particular judge's view of the case. A medical man, when sent for a house, presumes that the master of the house is responsible for t payment of his fees. In the case of domestic servants, even if su moned by the master or mistress of the house, he usually inquires whom the bill is to be sent; but in the case of a son of the house would naturally suppose that if the patient did not pay him th father would. X. Y. Z. will, of course, not take legal proceedin except upon legal advice.

F.R.C.S., in a communication which it would hardly be advisable the interest of the profession as a whole to publish, attributes t majority of the ills, referred to in the letters headed "The Times a Troublous," to the congested condition of the Register. To a certa extent he is right but the situation is one that we believe is curing itself to some extent; while he must remember that the duties which now fall to the lot of medical men are much more numerous and far-reaching in their scope than they used to be

Mr L. Roberts—Washing soda is to a certain extent corrosive and therefore is not so suitable for use in domestic cookery as the bicarbonate of soda, but used with due caution no harm would occur No cases of either illness or of death from the use of washing soda in cookery have come under our notice

Robin—We have no definite information on most of the points contained in our correspondent's letter but in the current Medical Directory the name of the present medical officer in charge is given as Dr M N Sharman to whom our correspondent had better write

Perplexed desires to know if a boy studying for the Army who is unable to close his left eye voluntarily and consequently shoots from the left shoulder would be handicapped as an artillery officer or for a line regiment His vision is good

X writes to us upon Sanatoria, but has not inclosed his name and address for our information

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423 Strand W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Office will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed London and Westminster Bank Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office 423 Strand London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates on this or on any other ground should be resisted The Proprietors of THE LANCET have for many years paid and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect *from the Proprietors* the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER THE LANCET OFFICES 423 STRAND, LONDON, ENGLAND.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 7, 1901.

An Address to Students.

WITHIN a month from now some 1500 young men in this country will commence the study of medicine. They are entering upon a path which they will have to tread for at least five years, if they faint not by the way. Cannot we who have passed over this path before and can look back upon its toils, its difficulties, and its dangers—cannot we of our knowledge, of our experience, impart some advice, some assistance to those who are coming after? We hope so. It is true that they must, as their seniors have done, learn by experience; but although they have to tread the paths for themselves we can, at least, warn them of some of the trials ahead of them and possibly save them a few detours.

EDUCATION AND INCLINATION.

For him who would study medicine there is no better equipment than a good general education. Even apart from the mental training which the acquisition of a good education must have given, general knowledge of a level much above that required at the preliminary examinations will not be wasted in the study of medicine. The medical sciences are so many-sided that there is but little knowledge which may not assist in unravelling some difficult problem, in enlightening some dark corner, of medical study. At the present day there is especially one item of a general education which is of inestimable value to the student, and that is a colloquial acquaintance with certain modern languages. A practical knowledge of French and German will open to the student's view stores of medical knowledge not available to him who knows only his native tongue. It is true that translations and extracts of articles from foreign periodicals will give a glimpse of this foreign literature, but the small portion thus rendered accessible to the English-speaking student will not bear comparison with what remains behind. We would not suggest that a large extent of general knowledge will in itself enable the medical man to practise his profession in any way more successfully, but it will facilitate in no small degree the acquisition of professional knowledge. Few things are more distressing to a teacher of medicine than to see the difficulties with which those have to contend who have entered on their studies insufficiently equipped in general knowledge; troubles encounter them at every step, and though these in time may be surmounted it is only at a woeful waste of zeal and energy.

Quite apart, however, from this preliminary equipment in general knowledge, all are not equally suited for the practice of medicine. It may well be asked, Is there no natural build of mind and body which specially fits a man for the onerous duties of medical practice, in which he becomes the arbiter of life and death to those who trust themselves to his care? Truly, there is. In medicine, as in every other vocation, there are certain qualities and attributes which are essential for the man who would follow it with satisfaction to himself and good chances of benefiting his neighbours by his work. And to all it is not given to possess them. In the very foremost rank we would put a liking for the work. Without going into the large and vexed question as to how far the choice of a profession should be left to a boy himself—for many other considerations must in most cases be allowed their due weight—we may express a very decided opinion that anyone who enters on the study of medicine without feeling any inclination for it will not unlikely find before his student days are over that he has mistaken his calling. That work is likely to be best done which is done *con amore.* He who has no special leaning towards medicine will feel to be a task what otherwise might be a genuine pleasure—for the practice of medicine should be a joy rather than a care. Among the most important requisites for the study and practice of medicine is a genuine love for the healing art.

THE ABSOLUTE NEED OF ACCURACY.

The second desideratum in the medical aspirant is accuracy, and this is as necessary in the student as it is when the momentous issues of practice hang upon the proper appreciation of facts Of all the earlier subjects which the medical student has to master few will question that the most important is anatomy. It is the very basis and foundation of all the medical sciences and a knowledge of it is as essential for the physician as for the surgeon. As Sir CHARLES BELL well expressed it, nearly 100 years ago, when speaking of the importance of one special portion of anatomy, "Without a knowledge of the arteries a surgeon can neither think sensibly nor act safely." Since, then, a competent acquaintance with the science of anatomy is a necessity for the medical man in whatever department of practice his work may lie, what manner of mind is needed for its acquisition? An accurate mind is essential. Accuracy in observation while he is dissecting a part will make the student's memory accurate in retaining what he then observes. The structural anatomy of the human body is so complete, so finite a science, that what a student once learns of it can never become out of date or be upset by some subsequent discovery. Individual variations may occur, but the general plan is practically invariable. Even the variations which are met with are, as a rule, few in number and well recognised, so that any anatomical fact which a student gleans from his text-book and verifies on the subject before him may be considered applicable to nearly every case with which he has to deal. Accuracy in observing and accuracy in remembering are alike important No man is more to be pitied than a surgeon who, without a due knowledge of anatomy, enters on an operation, for the greatest mortification a man can experience is a feeling of unfitness for the work which he has undertaken. Every incision is made with uncertainty, and the encounter with unexpected structures may render the operation of no avail, or may even cost the patient his life. Even in slight injuries or diseases an accurate knowledge of the normal anatomy of the part is absolutely essential to a reasonable hope of a trustworthy diagnosis and a successful treatment. Seeing, then, how important is an accurate knowledge of anatomy, it is obvious that no trouble can be wasted which is devoted to the obtaining of a competent knowledge of the subject. And for this accuracy is essential. Although we have taken anatomy as an instance of the importance of accuracy, the possession of this quality is equally desirable in all the ancillary sciences of which the medical student has to acquire a working knowledge. Numberless instances at once rise in our mind of the truth of this statement. but it is unnecessary to quote them, for our readers can hardly help recalling a dozen examples. And the accurate observation which the student has practised in his anatomical studies is the very best training he could possibly have for the accurate observation which is so much needed in clinical medicine and surgery.

THE RÔLE OF IMAGINATION.

There are many branches of the complex science of medicine in which a mental quality is needed which is often considered to be antagonistic to accuracy. This quality is "imagination." Medicine is ever changing. The facts of to-day become the doubts of to-morrow and the wild hypotheses of yesterday may take their place as the accepted theories of to-day. The medicine of the ancients appears to us to be largely erroneous and many moderns laugh at the ideas held by their predecessors. This is unwise, for many of the ideas we have to-day may well furnish matter for ridicule for those who come after us.

> "Our little systems have their day,
> They have their day and cease to be."

Hardly need we say that all the while, although with much ebb and flow, medical knowledge is steadily advancing. The greater part of the facts and theories of medicine are so firmly established that they can never be moved. Yet inasmuch as our foundations cannot be too firmly laid we should from time to time examine and re-examine even those facts of medicine which appear to be most definitely settled. For, to vary the metaphor, it may well be that some link in the chain of reasoning has been admitted without proof, that some step has been taken in haste without waiting for a definite demonstration.

No better instance of this can be quoted than the theory that bovine tuberculosis is a cause of tubercle in human beings. We are not now concerned whether Professor KOCH'S theory be true or not, for the argument is equally valid in either case. For many years it has been held that the milk of cows suffering from bovine tuberculosis was liable to cause the appearance of tubercle in those who were fed with it. The theory was accepted and acted on by everyone, both in this country and elsewhere, until Professor KOCH pointed out the absence of all proof that was satisfactory to himself of any connexion between the milk of tuberculous cows and human tuberculosis. This was where imagination came in. It suggested to Professor KOCH that this connexion had been prematurely assumed as true, and he investigated the matter and found himself unable to transmit bovine tuberculosis to other animals. The scientific world is against the great savant's views, but his departure from accepted theory will make it necessary to revise all the evidence bearing upon the question, and the consequence of this can only be a sifting and spread of information. This instance shows a valuable use to which imagination can be put, but it has other more common and yet more important duties. For the student imagination rightly used will give priceless aid in the understanding of the theories of physiology and pathology, though it is chiefly when he is qualified that he finds the value of imagination. If every symptom resulted from a single cause, diagnosis would be exceedingly simple, but little trouble would be needed to discover the cause of any malady, and treatment would become in most cases as simple as diagnosis. Unfortunately, it is not so; there are few symptoms which may not be ascribed to at least half a dozen different causes, and with many symptoms the possible causes are legion. Here is the rôle of imagination. The physician weighs all the symptoms and signs that he has elicited, and then by the aid of his imagination he endeavours to light on a lesion—one disease which will account for all these. In many cases the diagnosis is simple and no great play of the imagination is needed. Frequently, however, the symptoms do not all fit in with the most obvious diagnosis, and imagination has to suggest the explanation. Such imagination is not idle or flighty guessing in the least. Rather it is the art of swift deduction, where a right solution may be reached even though some logical step may be temporarily wanting.

EXAMINATIONS AND THEIR USE.

Nowadays all have to pass examinations, and the student of medicine has many. Examinations are at the best but an untrustworthy method of guaranteeing that a student is fit to practise his profession; but he must neither undervalue nor over-estimate them. They are of great use in directing the student's work into the best channels, and they serve to show him something of the standard of knowledge which is required. Examinations should, if possible, be taken at the due time and not postponed, for the habit of putting off an examination soon grows on the procrastinator. Should a failure occur, as is, alas, far from uncommon, let the student not despair, but examine into the cause of the want of success and remedy it before the next ordeal.

> "It becomes no man to nurse despair,
> But in the teeth of clenched antagonisms.
> To follow up the worthiest."

Some of the very soundest and most successful practitioners have occasionally failed in test examinations, and many will admit that the lessons they learned from the mortifying check to their careers proved useful to them at the time and afterwards. They learned the value of a little introspection, and anticipated a position in which they afterwards found themselves more than once when face to face with puzzling cases in practice. For when the final examinations are behind him, and the quondam student becomes the fully-qualified practitioner he must not imagine that his time of study has gone by. If he be wise he will for ever remain a student. All of us make mistakes, and he is truly wise who is willing to learn by his mistakes An error in diagnosis or in treatment loses part of its harm if he who made it finds it out and its reason, and thus learns not to commit the same error on another occasion. Thus he may be the better, the more accurate, physician for the error he once made. Time and experience are needed for the youthful physician to become a skilful diagnostician. Nearly 500 years ago BASIL VALENTINE wrote: "Only knowledge and experience and thorough investigation of nature make a trustworthy physician." As time goes on diagnosis may become almost intuitive and with some this diagnostic power rises to such heights that it appears marvellous to the less learned.

SYMPATHY AND DISCRETION.

There is a tendency, a great tendency, for the student of medicine to become in his hospital work a little careless of the feelings of his patients. This is doubtless due to no want of kindliness in his nature, but, in great part, to the fact that very many patients have to be seen in a short time of whom many are intellectually slow. Be the cause however, what it may the result is the same; the patients do not derive from the treatment all the benefit they should, and the student himself fails to give that degree of attention to the cases which under other circumstances he would have devoted. Any lack of sympathy, harmful in a hospital is even more prejudicial, if that be possible in private practice. The sick feel a need for sympathy; the feeling that his sufferings are disregarded by those around, that no obvious attempt is being made to alleviate them or to lighten his pangs, cannot but have a very harmful effect on the patient's mind, and through his mind on his body. On the other hand, a judicious expression of sympathy with the sufferer, a sympathy shown not merely in words but in the manner, the tone of voice, and the touch of the hand, will exert a favourable influence on the mind of the patient, on his appetite, on his general nutrition, and even on the morbid process itself. It is generally recognised that if a patient believes he will get well his recovery is far more probable than when his despondency as to the result of his illness depresses his vital powers. Necessarily the difference this can make in any disease cannot be great, but it may be quite sufficient to alter the "balance of power" and to incline the vital processes towards recovery. It were well for the student early in his hospital career to peruse TUKE's valuable work entitled "Body and Mind", he will there see many instances of the great influence the mind has on the body. The action of the body on the mind is more obvious and is therefore less likely to be forgotten. This manifestation of sympathy on the part of the physician must not degenerate into a mere humouring of the fads and fancies of the patient. To give way to every wayward imagination of a sick man will not tend to restore him to health, but a judicious firmness in insisting on those rules which the physician considers binding combined with a kindly yielding in those matters which are of no importance, will go far to assist the patient in his struggle with disease. The medical man must be a sympathetic friend as well as a scientific adviser and neither function must be allowed to lapse. His great endeavour should be thoroughly to understand his patient, to learn to recognise how much pain the patient is suffering and how far the complaints which are made to him depend not on the disease itself but on the patient's mental constitution. It is almost needless to say that this is exceedingly difficult and the end is best attained by the physician putting himself mentally in the position of his patient, imagining what his own feelings would be if he were afflicted with pneumonia or a broken leg and what he would like to have said and done to him under those circumstances. When the patient's confidence has been gained, then the physician will be in the best position to act for his good. Herein lies one of the chief benefits of "family doctors." When a medical man has known a patient from his earliest childhood; when, perhaps, he has even assisted in bringing him into the world; has attended him during infancy and childhood, perhaps through several severe illnesses; has seen him grow to manhood and to middle age; then, indeed as must be obvious, he knows to the full all his individual peculiarities—all the personal traits which exert, not only in health, but even more in disease, so great an influence on a man's life and conduct. A great part of the benefit of this "knowledge of the patient's constitution," as this kind of intimate familiarity with a patient's mind and body is generally termed, depends on the trust which the patient has in his medical adviser. This trust is shown not only in the confidence with which a man will put himself under treatment in a disease endangering his life, but also in the reliance which he places in his medical man's opinion on many matters, some of which are but remotely connected with the treatment of disease. Not even a clergyman enters more intimately into the life of the patient than does the medical man and this influence can work for great good. But the position carries with it enormous responsibilities. It is impossible to over estimate the sanctity of the patient's confidences or the privacy of any knowledge that the medical adviser may arrive at concerning him in the course of attending him professionally. The student cannot learn too early that it is the duty of the medical man to respect his patients to enter into their troubles, and to preserve their confidences intact. Unless he can display the qualities of sympathy and discretion the utmost scientific knowledge may only mislead him to the patient's detriment.

BODILY STRENGTH IS NEEDED.

There is yet another requisite both for the student and for the medical man concerning which space must be found to say a word or two. In each case good health is required. We do not endorse a suggestion made a few years ago, that every would be student of medicine should measure so many feet in height and so many inches round the chest, and should scale so many pounds. Height and weight are but sorry criteria of good health. Nevertheless, good physical health is almost essential. The strain of five years hard study is by no means slight, and a breakdown during the student days would be a rarer event than it is if more attention were paid to the bodily health. And though the strain before qualification is severe, much more severe is it when the medical man enters practice. Disturbed nights add their depressing effect to the exhaustion of laborious days, and nothing but a strong constitution can withstand this strain on health. To himself the physician owes it that he should not work beyond his strength and to those dependent on him it may mean all the difference between ease and direful poverty. Let every student husband his strength and live as befits a child of science soberly and discreetly. So will he much improve his chances of success as a student and will enter upon his life work with the pleasurable feeling first examination for the Fellowship of the Royal College of Surgeons of England is one of the hardest and most uncertain examinations known to us. In making the suggestions which follow we premise in the student a complete knowledge of the simpler works.

For the Preliminary Scientific Examination of London University Rideal's *Practical Organic Chemistry* (Lewis, 2s. 6d.), Tilden's *Inorganic Chemistry* (J. & A. Churchill, 10s.), Remsen's *Organic Chemistry* (Macmillan, 6s. 6d.), and Bernays' *Practical Chemistry* (J. & A. Churchill, 4s. 6d.) are recommended. Daniell's *Text-book of Physics* (Macmillan and Co., 21s.) should be supplemented by Deschanel's well-known volumes and such books as Catchpool's *Sound* (Clive, 3s. 6d.), Lowson's *Botany* (Clive, 6s. 6d.), and Wells and Davies's *Zoology* (Clive, 6s. 6d.) We understand that in October Messrs. Arnold will publish Mudge's *Biology*, a book which is intended exactly to fit the needs of this examination, while the course of botanical reading should include Scott's *Structural Botany* (Adam and Charles Black, two vols., 3s. 6d. each). For the first M.B. of the University of London and for the first Fellowship of the Royal College of Surgeons of England Morris's *Anatomy* (J. & A. Churchill, 36s.) is, on the whole, the best text-book, but the student should also read embryology by Schäfer and splanchnology by Schäfer and Symington in Quain's *Anatomy* (Longmans, 9s. and 16s. respectively) and revise his osteology from time to time by Gray's *Anatomy* (Longmans, 36s.) and his practical work by Cunningham's *Practical Anatomy* (two vols.; Young J. Pentland, 12s. 6d. each) or Brodie's *Dissections Illustrated* (Whittaker and Co., 42s.). For both these examinations Stewart's *Physiology* (Baillière, Tindall, and Cox, 15s.) or Foster's *Physiology* (Macmillan and Co., in four parts, 10s. 6d. each, and appendix, 7s. 6d.) should be read.

For the final medical examinations of the great universities no different text-books are absolutely required to those suggested for the final examination of the Conjoint Board, but the student's reading should be regularly supplemented by studying the valuable monographs in Allbutt's *System of Medicine*, the pages of the medical journals, and such works as Powell's *Diseases of the Lungs and Pleura* (Lewis, 18s.), Gowers's *Treatises on Neurology* (J. & A. Churchill, vol. i., 15s; vol. ii, 20s.), von Jaksch's *Clinical Diagnosis*, (Griffin and Co., 24s.), and Judson Bury's *Clinical Medicine* (Griffin and Co., 21s.). A sound knowledge of bacteriology will also be expected of the medical graduates of the principal universities, who will be expected to be familiar with the modern views of the etiology and prevention of infective diseases. Sternberg's *Bacteriology* (J. & A. Churchill, 24s.) and Crookshank's *Text-book of Bacteriology* (H. K. Lewis, 21s. net) are the best and most comprehensive modern works. For the final surgical examination of the University of London (that for the degree of M.S.) and for the final F.R.C.S. the first thing for the candidate to remember absolutely is that his anatomical knowledge must be as perfect as it was at his previous tests. If it be taken for granted that the student has a thorough knowledge of such a text-book as that of Rose and Carless, then the book to read is Tillmann's *System of Surgery* (Kimpton, 63s.). The book is thoroughly well written, comprehensive, and completely up to date, which can no longer be said of Holmes's *System* or even of Erichsen's splendid work. *A Manual of Surgical Treatment*, by W. Watson Cheyne and F. F. Burghard, is being issued in parts at prices varying from 10s 6d. to 18s. by Longmans. Five parts are published and a sixth is in preparation. This is a valuable book, sound, practical, and up-to-date; and the same may be said of Walsham's *Surgery*, now in its seventh edition (J. & A. Churchill, 15s). Such monographs as those by Bland-Sutton on *Tumours* (Cassell and Co., 21s.), by Treves on *Intestinal Obstruction* (Cassell and Co., 21s.), by Tubby on *Deformities* (Macmillan and Co., 21s. net), by Morris on the *Surgery of the Kidney* (Cassell and Co., 42s. net), by Waring on *Operative Surgery* (Young J. Pentland, 12s. 6d.), and by Marsh on *Joints* (Cassell and Co., 12s. 6d.) should also be read.

Recent Medical Literature.

During the past students' year many excellent works have appeared which have been highly reviewed in our columns but which cannot be called essential to the library of the student. A certain proportion of these text-books have been, and will be, read by very many students and if they are kept up to date where necessary will very possibly take the place in popularity of those now occupied by other works. Some text-books in these days of medical progress require annual revision; explanations once necessary become no longer so, new discoveries entail large additions, doubt is thrown upon accepted theories, importance is given in the medical curriculum to subjects which had previously been barely noticed, and so on. For any or all of these reasons a book that is to appeal to students from year to year must be revised almost annually. It follows from this that text-books which we now recommend as essential—as far as any one text-book can be essential to the student's education—may easily drop behind and its place be taken by another book more carefully brought up to date and more directly written to suit the immediate exigencies of the examination boards. During the past year a new edition of an excellent book on physiology has been published (*Elements of Human Physiology*, by Ernest H. Starling, M.D., F.R.C.P. Lond., F.R.S., fourth edition, much enlarged, 690 pages, with 317 engravings, 8vo, 12s. 6d. J. & A. Churchill). The book, as we said in our review of it, "gives the established facts in physiology in a very clear and logical fashion, and while it would appear in parts that he (the author) writes rather for the young physiologist than for the student of medicine, yet it must be remembered that a true study of physiology involves an accurate knowledge of organic chemistry." In surgery several new works or new editions of previously published works have appeared to which attention should be drawn. Mr. Henry Morris has published the Hunterian Lectures for 1899 (*On the Origin and Progress of Renal Surgery*. With 28 illustrations, 6s. Cassell and Co., Limited). A new edition of *Surgical Diseases of Children*, by Mr. Edmund Owen (third edition, revised and enlarged, with five chromo plates and 120 engravings, 21s Cassell and Co., Limited), has also appeared and is an excellent *résumé* of accepted knowledge on the subject written in a bright practical manner.

Among the numerous American works to which we have had to draw attention in our review columns during the year we may pick out for special notice *A Text-Book of the Practice of Medicine*, by James M. Anders, M.D., Ph.D., LL D (two octavo volumes, 1292 pages, fully illustrated, cloth 24s net. W. B. Saunders and Co.), which is a very complete and satisfactory book deserving a prominent place in every medical library. *A Text-Book of the Theory and Practice of Medicine*, edited by William Pepper, M.D., LL.D. (complete in two royal octavo volumes of about 1000 pages each, illustrated; price per volume, cloth 21s. net. W. B. Saunders and Co) is another first-class treatise. The articles are exhaustive in scope and the book as a whole is, as we stated at the time that it appeared, thoroughly practical and useful. *A Text-book of Surgery*, edited by Dr. W. W. Keene and Dr. J. W. White (two royal octavo volumes of 1250 pages with 500 woodcuts in the text and 39 coloured and half-tone plates, price, cloth, 30s. net. W. B. Saunders and Co) is another admirable text-book which has been revised and enlarged during the year. It is a complete and readable account of the science and art of surgery and is a fair reflex of the present position across the Atlantic. Two other American works illustrating well the genius of that country for productions neat in shape and encyclopædic in character may be mentioned One is *A Year book of Medicine and Surgery*, edited by GEORGE M GOULD (two volumes octavo of about 600 pages each, illustrated, price per volume 13*s* 3*d* net. W B Saunders and Co) The other is the *Illustrated Medical Dictionary*, by W A. NEWMAN DORLAND, M D, editor of the *Pocket Medical Dictionary* (octavo, 800 pages, 19*s* net W B Saunders and Co)

Professor WOODS HUTCHINSON, A M, M D, has written a work of singular interest and in a very attractive style (*Studies in Human and Comparative Pathology*, edited by Dr Edward Lake, 350 pages, price 12*s* 6*d* Henry J Glaisher) The study of comparative pathology is still in its infancy, but it is a most interesting and instructive study, and any senior student who desires to read a book which no one but a person properly grounded in medical science could follow is recommended to this work The book would have no direct bearing on his examinations, but would give him valuable ideas Dr G V POORE'S addresses on Medical Jurisprudence (*A Treatise on Medical Jurisprudence*, illustrated, 530 pages, price 12*s* John Murray) is a work which, like Dr Woods Hutchinson's, is not only full of information but charming reading The author has a thorough grasp and knowledge of his subject By means of a free employment of illustrative cases drawn from the records of the law courts and from large personal experience the dry details are endowed with lively interest which is likely to imprint them on the student's memory Mr WALTER C C PAKES, the bacteriologist to Guy's Hospital and demonstrator in sanitary science in that school, has produced a very good text book (*The Science of Hygiene a Text book of Laboratory Practice*, pp xv 308, price 15*s* Methuen and Co) The work, as we said when we reviewed it, is "wide in scope and accurate in detail" It covers the whole of the laboratory work required from candidates for the various diplomas in public health and, indeed, it covers much more than this, and will be found a good work of reference for medical officers of health generally

OLD FRIENDS

We regretfully leave out of our list many old friends but we have done so deliberately, not because we are otherwise than certain that everyone must derive much benefit from reading the works of Erichsen, Holmes, Playfair, and Bristowe for example, but because in these days of an extended curriculum and frequent examinations it is of the first importance to the student to have his knowledge always on hand, clear, well-defined, and certain A text-book that in details especially in details of classification, has dropped behind might possibly muddle a student or betray him into error By all means let him when he has passed his examination, read these excellent books but he had better wait until his days of probation are over before studying the evolution of medicine We have also made no attempt whatever to indicate the best books to employ in the more special branches of medical and surgical work At the classes and clinical demonstrations dealing with these subjects, as in the laboratory, the professor or lecturer will tell his pupils what books he desires them to read and the particular book will depend upon the scope of his addresses and demonstration. In previous Students Numbers of THE LANCET will be found an exhaustive list with critical comments of all the best text books

UNIVERSITY OF LONDON

SINCE 1864 suggestions for converting the Examining Board of the University of London into a body exercising distinct teaching functions have been continually before the Senate and Convocation, but an efficient plan is even yet far from being completed or in working order The scheme for the *concentration of medical studies* and the revision of the curricula for the early education of medical students are held over until the next winter session, and it will take a very considerable time before the regulations affecting the future of medical education in London will be decided on, much less made operative There is a good deal of talk at the various committee meetings, but very little progress, for there is no agreement on principles, and *therefore, much difference of opinion on details*

The history of the opposition to a real teaching University in London is a very curious study In 1864 Mr. Bompas and Dr Sansom appear to have made the first move in this direction after the original foundation of the University, but their proposals were at once rejected by the Senate *Dr Pye Smith's* resolutions in 1878 were also rejected, as were similar ones afterwards adopted by Convocation in 1881 and 1882. The first important movement outside the members of Convocation began in 1884 and it then took 14 years for a Bill to be passed through Parliament appointing a statutory commission to arrange the details by which the University should be guided in carrying out its teaching duties Although the Senate and other authorities nominated by the Statutory Commission were elected in October, 1900, no educational regulations are yet forthcoming

The dissatisfaction which most educational experts in London felt with the attitude of the University of London towards higher education in London led in November, 1884, to the formation of an association for promoting the establishment of a teaching university for London under the presidency of Lord Reay and the vice-presidency of Sir George Young, and the association immediately entered on an active propaganda in support of its principles and objects These were defined by the association as follows —

1 The organisation of university teaching in and for London, in the form of a teaching university, with faculties in arts, science, medicine, and laws. 2. The association of *university examination with university teaching, and the* direction of both by the same authority 3 The conferring of a substantive voice in the government of the university upon those engaged in the work of university teaching and examination 4 Existing institutions in London of university rank not to be abolished or ignored but to be taken as *the basis or component parts of the* university, and either partially or completely incorporated with the minimum of internal change. 5 An alliance to be established between the University and the Professional Corporations, the Council of Legal Education as representing the Inns of Court, and the Royal Colleges of Physicians of London and Surgeons of England.

A sub committee was appointed to draw up a scheme in accordance with these objects and it attracted much attention and support from the teachers of London On Lord Reay being appointed to the Governorship of Bombay the late Mr John Marshall accepted the presidency of the association. This movement naturally alarmed the Senate and Convocation of the University of London, as it was directly aimed to fill up the gap in London education, which their institution had been originally formed to occupy, but they preferred to become an Imperial examining board instead of a local university Many of the graduates, however, were in favour of reforming the University on the lines laid down by the association so on Jan 6th, 1885 a special committee of 40 members was appointed to consider its proposals On Feb 24th they reported to Convocation that the objects of the association would, if carried into effect by the University add to its usefulness and importance This report was carried by a large and influential majority and the committee was re-appointed A scheme embodying these proposals was drafted by a sub-committee with Lord Justice Fry as chairman but after a prolonged discussion on July 28th and Nov 3rd of the same year was rejected by 43 votes in favour of an amendment of Mr (now Sir) Philip Magnus to refer back the scheme for consideration and to increase the number of the special committee by 20 names Most of the members of the special committee at once resigned Mr Magnus's scheme, which varied but little in its general plan from that of Lord Justice Fry, was brought before Convocation of Dec 8th, 1885 and was referred to a special committee of 25 members to work out the details and lay them before Convocation

Meanwhile the question of degrees for London medical students had been introduced to the profession by the late Dr Walter Moxon in a most lucid and powerful article in our columns on July 25th, 1885 entitled "The Demand for Equitable Graduation in the South of England, being a Study of an Unfulfilled Duty of the Royal Colleges of Physicians and Surgeons." He pointed out that these Colleges, if empowered to grant medical degrees, would at once constitute a teaching university in London and be the nucleus or centre of growth of a more general teaching university. A memorial in favour of this movement was presented to these Royal Colleges bearing the signatures of over 600 teachers, practitioners, and students of medicine. A committee of delegates of the two Colleges had already presented a report, which was fully considered in October, 1885, and a motion moved by Dr. (now Sir) Samuel Wilks was adopted in the following terms: "That it is desirable that persons examined by the Royal College of Physicians of London and the Royal College of Surgeons of England conjointly and found duly qualified, either by the ordinary or an additional qualification, should have a degree in medicine and surgery conferred on them." It is interesting to know that Dr. Fincham, Dr. S. O. Habershon, Dr. C. West, Dr. (now Sir) William Gowers, Dr. (now Sir) W. H. Broadbent, Dr. Sansom, Dr. Barnes, Dr. Wilson Fox, Dr. Norman Moore, Dr. Moxon, Sir Andrew Clark, Sir Henry Pitman, and Sir William Jenner all spoke in favour of the movement. This preliminary report, having been referred to the Councils of the Royal Colleges and reported on, was further considered by the committee of delegates at very frequent meetings and they again reported in December, 1886, in favour of the granting of a degree in medicine and surgery to London medical students by the Royal Colleges and that an application for this purpose should be made to the Crown. A carefully drawn up statement giving the reasons for this step accompanied the report of the delegates. This final report came before both Colleges on Dec. 16th, 1886, after a most interesting discussion at the Royal College of Physicians of London as to whether the degree should be conferred by the Colleges acting by themselves alone or by some university outside the Colleges but on which they could be represented. This obviously was intended to include either a reformed London University or such a university as was contemplated by the Teaching University Association. On the 23rd an amendment taking the latter view was defeated by a large majority and the two Colleges were now definitely pledged to go on with their own scheme.

On June 29th, 1886, Mr. Magnus's scheme, which differed but little in its essentials from that of Lord Justice Fry, was passed by Convocation, but was no more acceptable to the Senate than former ones had been. The year 1887 was practically spent in conferences between the various bodies interested and three new schemes were ultimately brought forward, one by the University of London as representing the views of the Senate; a second by the Royal College of Physicians of London and the Royal College of Surgeons of England; and a third by University College and King's College, London. All these applications were put in for hearing before the Privy Council before Jan. 16th, 1888, but in consequence of a multiplicity of petitions for and against them, and of the great importance of the question, Her Majesty's Government advised the appointment of a Royal Commission. In May, 1888, the Commission was formed and held its first meeting on June 2nd. Lord Selborne was the chairman, and the other members were Sir James Hannen, Mr. Brodrick, Warden of Merton College, Oxford, Sir William Thomson (now Lord Kelvin), Professor (now Sir George) Stokes, Vice-Chancellor Ball, and Dr. Welldon, with Mr. J. L. Goddard as secretary. The Warden of Merton College resigned after the first sitting on a question of procedure as to the limitation of the proposed evidence. After hearing most voluminous evidence the Commissioners issued their report on April 29th, 1889, in which the petition of the Royal Colleges to grant degrees in medicine and surgery was unanimously rejected. A reconstitution of the University of London mainly on the lines of the scheme of Lord Justice Fry was unanimously recommended to be tried, but in a separate note the members more immediately connected with education—viz., Sir William Thomson, Professor Stokes, and Dr. Welldon—declared their preference for the establishment of a new teaching university in London without interfering with the work so ably done by the existing institution, although they would permit the existing institution to undertake the new duties if it could, which they doubted. If a proper scheme in full accord with the recommendations of the Commissioners were forthcoming from the University of London the petition of University and King's Colleges to be constituted into a university was not to be granted. Conferences between the various bodies interested and the Senate and between the Senate and Convocation as to the modifications required to meet the views of the Commission led to no result, so Lord Cranbrook, as Lord President of the Privy Council, wrote to the University of London at the end of 1890 asking their intentions with regard to a new Charter. After many futile attempts a finally revised scheme "was drawn up" by the Senate and submitted to Convocation in 1891. This was too complicated to receive much support and was rejected by a large majority.

Two years of conferences had led to no result and Lord Cranbrook at once gave notice that he would fix an early date for a meeting of a Committee of the Privy Council to take into consideration the petition of University and King's Colleges "to be a university in and for the London district, having power to grant degrees in the Faculties of Art, Science, and Medicine, with power to add other faculties." The Lords of the Privy Council passed the Draft Charter of this new University, leaving the two Royal Colleges to determine whether they would accept the representation offered to them in the new University. This was declined, but the alternative representation of the 10 medical schools was accepted, and so they became, with University and King's Colleges, constituent colleges in the University. The University was to be called the Albert University, but afterwards, when the Joint Grand Committee of Gresham College had given their full support to the scheme, the name was by consent changed to that of "Gresham." The draft charter had to be laid on the table of both Houses of Parliament for 30 days. During the Parliamentary recess a most determined opposition was started by the authorities of the Victoria University and the provincial medical colleges, supported by many members of the Senate and Convocation of the University of London, by Bedford College, the Birkbeck Institute, and similar bodies, and the University Extension Society. Many London professors, especially in science, urged the formation of a professorial university in opposition to a federated one. Parliament assembled in February, 1892, and on March 3rd Lord Salisbury received a deputation representing these interests, at which Vice-Principal Rendall and Mr. Chamberlain were the principal speakers. On March 9th the Draft Charter was remitted by Mr. Balfour for reconsideration and on April 25th a new Royal Commission was appointed "to consider and if they think fit alter and amend the proposed Charter remitted in compliance with an address of the House of Commons, so as to form and report to us a scheme for the establishment under Charter of an efficient teaching university of London." The members of the new Commission were Earl Cowper (chairman), Lord Reay, Bishop Barry, Lord Playfair, Vice-Chancellor Rendall, Professor Ramsay, Professor Sidgwick, Canon Browne, Mr. Anstie, Q.C., Mr. R. C. Palmer, Sir W. S. Savory, Sir G. M. Humphry, and Professor Burdon-Sanderson, a well selected group of men representing practically all the interests involved in the solution of the question.

The sittings began on May 21st, 1892, and after hearing most lengthy, and in many respects contradictory, evidence, as well as a recapitulation of that put before Lord Selborne's Commission, the new or Cowper Commission were not able to report before January, 1894. The chief recommendations then were that there should be one university with teaching functions confined to London and that the existing university should be reconstructed so as to carry on this work without interfering with its present duties, and that University College, King's College, Bedford College, the Royal College of Science, the City and Guilds of London Institute, certain theological colleges and colleges of music, and the London medical schools should be at once admitted as schools or colleges in the University. The students were to be divided into those attached to those institutions (internal or collegiate students) and those unattached (external or non-collegiate students). The examinations for the internal students were to be arranged by an Academic Council of the members, and those for the external students by a board specially appointed for that purpose. The final examination for the degrees in either were to be the same or to represent the same standard of knowledge, and "identical, so far as identity is consistent with the educational interests of both classes of students." The governing body was to be a Senate composed of the Chancellor and 65 other members. It was also proposed that these recommendations should be effected, not by Charter, but by legislative authority and by the appointment of a Commission with statutory powers. [illegible] ed by the Royal Colleges [illegible] ing's College after some [illegible] Deputations in support [illegible] e were received by Lord [illegible] ere told that the Government would "consult very largely the vote of Convocation, whenever it is taken." On Jan. 22nd, 1895, a meeting of Convocation took place, when 206 voted in favour of the scheme and 174 against. On May 14th, at the next meeting, Mr. Bompas endeavoured to get the resolutions which had been passed at the last meeting rescinded, but he was defeated by 238 votes against 116 As if to show the futility of consulting the graduates Mr. Napier, LL.D., a marked opponent of the scheme, was elected a Fellow of the Senate at the same meeting by 1231 votes, whilst only 738 graduates supported Mr. Cozens-Hardy, one of its most prominent and influential advocates.

On May 9th, 1895, Lord Playfair introduced a Bill in the House of Lords to carry out the recommendations of the Cowper Commission. The Bill was a very short one and the operative clause was as follows :—

1. The Commissioners shall make statutes and ordinances for the University of London in general accordance with the scheme of the report hereinbefore referred to, but subject to any modifications which may appear to them expedient after considering any representations made to them by the Senate or Convocation of the University of London or by any other body or persons affected.

2 In framing such statutes and ordinances the Commissioners shall see that provision is made for securing adequately the interests of non-collegiate students.

3. All such statutes and ordinances shall be laid forthwith before both Houses of Parliament, and shall come into operation on the expiration of 40 days after they have been so laid, and shall have effect as if enacted by this Act, but shall be subject to alteration in the manner provided by such statutes and ordinances.

The Bill passed its first reading, but its further progress was stopped by the resignation of the Government. On the accession to office of the new Ministry an influential deputation waited on Nov. 28th, 1895, on the Duke of Devonshire, as Lord President of the Privy Council, asking him to introduce a similar Bill, but with a right of appeal to the Privy Council added. The deputation met with little encouragement and Sir John Lubbock in his election address adopted the strange position that every graduate should be able to exercise the right of veto even by a proxy vote and without a personal attendance at Convocation, so that the prospects of the Bill at the end of 1895 were far from hopeful. The opposition of the graduates was further shown by the rejection of Sir Joseph Lister (now Lord Lister) as a Fellow in favour of the late Mr. Walter Rivington in June, 1896. Another amended Bill was introduced in the House of Lords and it passed but was withdrawn in the House of Commons. Other tentative measures were tried in 1897. Some important points not in the former Bills were now introduced by way of compromise, and these satisfied a large section of Convocation which had formerly been actively hostile, although many graduates under the leading of Mr. Fletcher Moulton still continued a strenuous opposition The Bill was, however, again introduced in the House of Lords by the Lord President on Feb. 21st, 1898, when it passed through the various stages without material alteration. It was then introduced in the House of Commons and passed the second reading on June 15th, when it was at once referred to the Standing Committee on Law. It was returned from this body practically unaltered and although many obstructive amendments—formerly defeated—were again urged it passed successfully through the Committee stage in July and received the Queen's assent on August 12th, 1898

The Statutory Commission was composed of Lord Davey, the Bishop of London, Sir William Roberts, M D, Sir Owen Roberts, Professor Jebb. Professor Michael Foster, M.D, and Mr. Edward Henry Busk, LL.B. Mr. T. Bailey Saunders was appointed secretary to the Commission. The statutes were published Feb 13th, 1900.

During the sittings of the Statutory Commission confidential draft reports were sent to the Clerk of Convocation. The first report dealt with the questions of the constitution of the University and asked for any representations which Convocation might desire to offer on degrees and examinations. The suggestions were very numerous, but had no influence with the Commission, although its attention was specially called to the fact that the registered graduates in medicine and surgery would only be represented by two members of the Senate, whilst arts and science were each to have six and music one. Six months later the concluding portion of the confidential draft report was forwarded for considerations affecting the schools and teachers of the University. In spite of the recommendations of Convocation engineering was made into a distinct faculty instead of being included under science, and economics and political science (including commerce and industry) were also separated into a faculty. The students in these subjects will proceed to degrees in science, but will have no separate representation on the Senate.

Early in the session of 1900 the new statutes obtained Parliamentary sanction and received the assent of Her Majesty the Queen without alteration. The University, after some very delicate negotiations, was transferred to the Imperial Institute building. The society known as the Imperial Institute surrendered the lease of that building to the Government, who granted the use of the central and eastern portions to the University of London substantially on the same terms as the former building in Burlington-gardens was held. "The University does not acquire its title from or under the Imperial Institute; it will have no relation with that body; it will not inherit any of its duties or liabilities." Convocation is asking for three of the best rooms in the house for a writing room, a graduates' club-room, and a room for conversation and other social purposes, and that these should be properly furnished.

The statutes as published by the Statutory Commissioners are practically identical with the recommendations of Lord Cowper's Commission in January, 1894. The visitor is Her Majesty in Council (now His Majesty). The Chancellor in future will be elected for life by the graduates in Convocation; the Vice-Chancellor will be elected by the Senate from its own body and the Chairman of Convocation by the members of Convocation; and 56 members of the Senate will include the Chancellor and the Chairman of Convocation. The other members are—16 chosen by Convocation; 18 by various educational bodies; 16 by the faculties; and four Crown members. The Senate is the supreme governing and executive body of the University and will have the custody and use of the common seal of the University, and the entire management of, and superintendence over, the affairs and property of the University. There are three standing committees of the Senate whose functions will be only advisory. These are (1) the Academic Council, of 16 persons, appointed to the Council by the members returned by the respective faculties, who will advise on the courses of study for internal students and any matter relating to these students; (2) the Council for External Students, of 16 members, elected by Convocation, to advise on the superintendence, regulation, and conduct of the examinations for such students, and for the equalisation as far as possible of the standards of knowledge and attainments prescribed for the degrees conferred upon external and internal students respectively; and (3) a board made up of an indefinite number of members of the Senate to promote the extension of University teaching. Convocation elects the next Chancellor and its own chairman and deputy chairman There are eight faculties—viz, theology, arts, laws, music, medicine, science, engineering, economics and political science. The members will be chiefly teachers and will consider and report on any matter referred to them by the Senate or on any matter relating to courses of study or granting of degrees. Boards of studies will also be formed at the discretion of the Senate The members of the Faculty of Medicine elected to the Senate, and therefore on the academic council, to regulate the courses of study and granting of degrees to medical students are Dr Rose Bradford, Dr Kingston Fowler, and Dr. E C Perry Sir T. Barlow and Dr. J. Frank Payne are returned by Convocation, Dr. Allchin and Dr. Pye-Smith represent the Royal College of Physicians of London, Mr. Pearce Gould and Mr. Howse the Royal College of Surgeons of England, and Dr T. Buzzard now represents King's College, London. The elections to the Senate took place on Oct. 13th, 1900

Since the formation of the reorganised University last year there seems to be but little progress in its practical work.

Teaching remains where it was and examinations have undergone no change as to either routine or suitability. The two important questions of the concentration of medical studies and the rearrangement of the curriculum for the matriculation, the preliminary scientific M.B., and intermediate M.B. examinations have been discussed by the Boards of Intermediate Medical Studies of the Faculty of Medicine. For the matriculation examination another examination for internal students or some alternative should be recommended in its place. At the preliminary scientific M.B. examination the arrangements suggested are evidently more practical than those now in use, but the terminal or sessional examination at a school of science or medical school will probably be adopted instead of the present preliminary scientific M.B. The report on the intermediate M B. is mainly interesting from the divergence of opinion as to the retention of organic chemistry in the syllabus for this examination and as to the necessity of there being a "honours" list.

The "concentration of medical studies" committee also reported in July, 1901, but the differences in opinion at the different medical schools were so great that, like the report on curricula, it was decided to postpone the further consideration of the matter until the winter session. The decision of these questions lies with the Senate and its Academic Council and it is not likely that any definite regulations will be published for a very long time yet. The whole procedure of the University is too cumbrous to affect the course of any present, or perhaps we may add any coming, student during the next two or three years. The Senate, we hear, has been largely concerned with the idea of teaching Chinese in connexion with the University, hoping that the China merchants in the City of London will endow the chair and endorse the scheme. There is still some difference as to whether colloquial or philosophic Chinese is what is wanted by the merchants or by the learned scholars. We would draw their attention from this novel problem to the more familiar one in the statutes. "The Senate may make arrangements with the Royal College of Physicians of London and the Royal College of Surgeons of England, or either of them, to conduct jointly with the Senate examinations in such portions of the subjects included in the course of study for a medical degree as may be agreed upon between the Senate and these Colleges, or either of them, and may also make similar arrangements with other corporations and institutions holding professional examinations in subjects included in other courses of study." We have as yet heard of no action being taken towards this great relief to the examinations of the medical student.

The arrangements for the courses of study for medical students and the granting of degrees are in the hands of the Senate, and considering that more than 30 years have been spent in endeavouring to found a real university in the metropolis it is only a bare justice that pupils from 1864 who were debarred from obtaining a true medical degree and had to be content with licensing qualifications only should have the opportunity of obtaining a degree on an examination test only and without undergoing further and unnecessary curricula of study. A final examination test, mainly practical, in medicine, surgery, obstetric medicine, and hygiene, would be all that should be required and could easily be made thoroughly efficient. The medical profession in London and the provinces has ever been most active to secure for past, present, and future medical students in London a degree on similar terms to those which are granted to the students in the Scotch and provincial universities, and it lies with the Senate of the existing University of London to grant this just demand.

SOME OF THE CHIEF APPOINTMENTS HELD BY MEDICAL MEN.

Medical Officer to the Local Government Board.—This appointment is in the hands of the President of the Local Government Board for the time being, and has hitherto been filled by the promotion of one of the two assistant medical officers of that Board.

Medical Inspectors of the Local Government Board.—These appointments also are made by the President of the Local Government Board. Qualification and experience in public health are taken into consideration. The Board employ 11 inspectors; also a director of the vaccine lymph station, two vaccinators, two medical inspectors for Poor-la purposes, and a water analyst.

Medical Officers to Poor-law Districts.—These appoin ments are made by the guardians of the union or parish i question, subject to the approval of the Local Governme Board, which approval is primarily concerned with th medical and surgical qualifications of the persons appointe and the locality of their residences. As a rule the sam person may be appointed medical officer for the workhou and for the district; but the appointments of district medic officer and workhouse medical officer may also be hel separately. The appointment usually lasts during the lif of the holder.

District Medical Officers of Health.—The appointmen are made by the urban or rural district council in questio subject to the sanction of the Local Government Boar which sanction takes account of qualifications, salary, are of district, and place of residence.

County Medical Officers of Health.—The appointments a made by the respective county councils, with whom th question in all its details absolutely rests. The Loc Government Act of 1894 has transformed the sanita districts created by the Public Health Act of 1875 into urba and rural districts, subject to district councils. The councils must, and county councils may, appoint medic officers of health, subject to a provision that a county medic officer may at times act for a district council instead of th district council appointing its own officer. The duties county medical officers of health are defined by Acts Parliament. They consist, generally speaking, of examinin and reporting to the local authority all matters dangerous health within their district, not otherwise provided for b special Acts. No appointment of medical officer of healt may be made unless an advertisement of the salary to b assigned and of the day of election has appeared in som public local newspaper at least seven days previously.

Lord Chancellor's Visitors in Lunacy.—There are tw medical visitors in lunacy nominated by the Lord Chancellor. The appointments are usually bestowed on gentlemen who have distinguished themselves in psychologica medicine, but who have not within two years been intereste in any house licensed for the reception of persons of unsoun mind. These appointments debar their holders from privat practice; their duties consist in the supervision and visitin of lunatics for whose welfare the Court of Chancery i responsible.

Prison Medical Service.—The medical officers attached to the larger prisons are required to devote their whole time to their official duties. Forms of application can be procured from the Secretary to the Prison Department at the Home Office, as all appointments are made by the Home Secretary. The salary commences at £250 per annum, with free quarters or an allowance in lieu thereof. The duties of a prison surgeon consist in visiting, examining and attending the prisoners, in attending the officers and staff of the prison with their families, and supervising the sanitary arrangements of the prison. The attendance on prisoners is subject to certain regulations, which permit the calling in of a medical practitioner from outside should circumstances demand it, and which forbid the performance of serious operations, except in urgent cases, without previous consultation with another medical practitioner.

Medical Officers of the Mercantile Marine.—The Merchant Shipping Act, 1894, directs (Section 209) that every foreign-going ship having 100 persons or upwards on board shall carry a duly qualified medical practitioner. Ship's medical officers, however, are more often appointed under the part of the same Act relative to "emigrant ships." For the purposes of the Act an emigrant ship is defined as one which carries more than 50 steerage passengers, and a steerage passenger is defined as one who is not a cabin passenger. Section 303 provides that a medical practitioner shall be carried on board an emigrant ship where the number of steerage passengers exceeds 50 and also where the number of persons on board (including cabin passengers, officers and crew) exceeds 300. A medical practitioner shall not be considered to be duly authorised for the purposes of this Act unless (*a*) he is authorised by law to practise in some part of His Majesty's dominions or in the case of a foreign ship in the country to which that ship belongs; and (*b*) his name has been notified to the emigration officer at the port of clearance, and has not been objected to by that officer; and (*c*) he is provided with proper surgical instruments to the satisfaction of that officer. The remuneration for these appointments is extremely variable, ranging from a free passage to the port of destination to a handsome salary during continuance in the service. The appointments are, of course, made by the various firms of shipowners and the applicants for the appointments on the first class lines are numerous Nowadays only younger men get the good berths, and an effort is made to retain their services

Medical Inspectors of Merchant Ships —These are appointed by local marine boards when the Board of Trade requires them to do so, or at ports where there is no Local Marine Board, by the Board of Trade Medical Inspectors of seamen are appointed in the same manner, and the emigration officer at the post of clearance may appoint a medical inspector of passenger ships

Factory Surgeon —Under the Factory and Workshop Act certifying surgeons are appointed by the inspectors of factories The duties are to certify as to the fitness for employment of children and young persons about to be engaged in factories and workshops and *to investigate and report on accidents* Certificates of fitness for employment have to be given after a personal examination of the person named therein at the factory or workshop There is a scale of fees for investigating and reporting on accidents which is sanctioned by the Secretary of State. The fees are low, but in any intricate case, or when any peculiar circumstances arise either in making the inquiry or in framing the report, the inspectors may recommend a higher fee, so that no fee exceeding 10*s* be assigned for any one accident, and provided the reason for assigning such higher fee be stated by the inspector When a certifying surgeon receives notice of an accident at a factory or workshop he must proceed thither with the least possible delay and make a full investigation as to the nature and cause of the death or injury caused by the accident and within the next 24 hours send a report to the inspector of factories For the purposes of such inspection he has the same powers as an inspector of factories, with power to enter any room to which the dead or injured person may have been removed The same regulations and provisions as in the case of accidents apply to cases of lead, phosphorous, or arsenical poisoning and to cases of anthrax occurring in a factory The duties of a factory surgeon include also the making of a report annually to the Home Secretary as to the persons inspected by him, while among his powers, other than those mentioned, is that of inspecting at all times the register of accidents which the occupier of a factory is by law compelled to keep

Public Vaccinator —These are appointed by the guardians in unions and parishes A candidate for this office must hold a certificate of proficiency in vaccination. The contract under which the public vaccinator undertakes his duties is in accordance with a form prescribed by the Local Government Board which also has power to make rules with regard to his duties and remuneration. Except in the case of the medical officer of a workhouse the contract must provide for a payment to the public vaccinator of not less than 1*s* in respect of each child registered in the district from Sept 1st, 1898, or resident there and afterwards registered or not registered at all, except where such child has before attaining the age of four months died, or been removed or had small pox, or been duly certified as vaccinated by another practitioner, or where a certificate of exemption has been obtained by the parent, a payment of not less than 5*s* for each successful primary vaccination or revaccination at the home of the person vaccinated, and a payment of not less than 2*s* 6*d* for each successful primary vaccination of a person other than a child, or successful revaccination at the surgery or elsewhere than at such home No payment is to be made for revaccination of a person less than 10 years old or who has been revaccinated within 10 years. These payments include postage unless otherwise agreed In the case of a workhouse medical officer a fee of not less than 2*s* 6*d* is to be paid for each successful primary vaccination or revaccination A visit must be paid to the home of the child on the request of its parent or custodian, or after notice from the vaccination officer, between 9 A M and 4 P M, and 24 hours notice must be given to the parent or custodian, unless otherwise arranged, and all vaccinations must be duly posted in a register to be kept in a prescribed form Vaccinations must be with glycerinated calf lymph or other lymph issued by the Local Government Board and otherwise in accordance with prescribed regulations

Medical Referees under the Workmen's Compensation Act 1897 —These are appointed by the Home Secretary and must be "men of independent position and high standing in their profession," while preference is given to those whose experience fits them for the duties to be performed by them These consist in examining and reporting upon accident cases referred to them in which claims made by workmen for compensation under the above Act are disputed by their employers Medical referees act as medical advisers or assessors to the committees, arbitrators, and county court judges who decide these cases, and they are not called as witnesses, though they may be requested to be present at the hearing of a matter in which there is diversity of evidence on surgical questions The fees approved by the Treasury are two guineas for a first reference with examination and written report, one guinea for a further written statement or a second or subsequent reference, and three guineas for attendance at the proceedings The number of cases referred must necessarily vary considerably according to the danger of the industries prevailing in different districts The Act of 1897 now applies to agricultural labourers of all *kinds, but accidents in agricultural labour* are of rare occurrence

Colonial Appointments —West Africa and the West Indies are the place where medical officers are chiefly required. As vacancies occur, which are not very frequent the Colonial Office fill them in British Guiana Jamaica Trinidad, Windward Islands Leeward Islands British Honduras, Fiji, Sierra Leone Gambia, Gold Coast, Lagos, Ceylon, Straits Settlements Hong-Kong, Cyprus, Gibraltar St Helena, and the Falkland Islands In Ceylon and Jamaica local candidates usually receive the vacant appointments West [illegible] charge of a dis[illegible] house, asylum, [illegible] the aged and children In West Africa the medical officers are also required to take charge of any hospital, public dispensary, lunatic asylum or other Government institution at their respective stations to supervise the sanitation of the district, to perform vaccination, and to give gratuitous attendance to all Government officials and in most cases, the families of such officials also All applications should be made to the Colonial Office

THE SANITARY INSPECTORS' CONFERENCE —The annual conference of the Sanitary Inspectors' Association was held this year in London, the hall of the Carpenters' Company having been generously offered for the purpose Apart from the transaction of business and the reading of papers the members of the conference made some interesting visits to some of the great sanitary stations of London. After hearing papers on the main drainage system of London by Sir Alexander Binnie and on the bacterial treatment of sewage by Dr Clowes, chemical adviser to the London County Council, the conference proceeded by river to the sewage works at Crossness where the coke beds were inspected and the methods of dealing with raw sewage, concluding the day's proceedings by a visit to the works of the Sanitas Company at Limehouse This company, owing to the expansion of their business, have recently acquired new premises in which now, as well as in the old premises at Bethnal Green the various sanitas products are made The process by which sanitas is made was watched with considerable interest As is well known, it depends upon the facility with which essential *oils* take up oxygen turpentine and eucalyptus oil being commonly used for the purpose These oils under continued treatment with air and water at a certain temperature take up oxygen forming peroxides, hydrogen peroxide being contained in the water and chiefly camphor peroxide being retained in the oil The process is of some duration The germicidal disinfectant and deodorant properties of sanitas are due to the facility with which it yields up oxygen Though as powerful as carbolic acid this fluid is quite non poisonous. The company sat down afterwards to lunch and in the speeches which followed Sir James Crichton Browne, who presided, referred to the work of the Sanitary Inspectors Association and stated that it was most important for them to know exactly how the antiseptic and deodorant agents with which they came officially into contact were prepared and to what their efficiency was due Mr Kingzett afterwards gave a demonstration of the way in which sanitas and sanitas products acted. The annual dinner of the association was held at the Holborn Restaurant, when Sir Hugh Gilzean Reid, the president of the association occupied the chair

SESSION 1901-1902.

◆

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

Registration of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in medicine:—

Every medical student shall be registered in the manner prescribed by the General Medical Council. No medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council and has produced evidence that he has commenced medical study. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration. The registration of medical students shall be placed under the charge of the branch registrars. Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing; and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and evidence that he has commenced medical study. The branch registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration. Each of the branch registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. Applications for special exceptions are dealt with by the Students' Registration Committee, which reports all such cases to the Council.

The Preliminary Examination in General Education, required to be passed previously to registration as a medical student, shall be as follows:—

"1. English language, including grammar and composition. 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors 3. Mathematics, comprising (*a*) arithmetic, (*b*) algebra, as far as simple equations, inclusive; (*c*) geometry, the subject matter of Euclid, Books I., II., and III., with easy deductions 4 One of the following optional subjects: (*a*) Greek, (*b*) French, (*c*) German, (*d*) Italian, (*e*) any other modern language."

In many cases the Council will not accept certificates of pass in Preliminary Examination in General Education unless the whole of the subjects included in the Preliminary Examination required by the Council for Registration of Students of Medicine have been *passed at the same time*

Professional Education.—The course of professional study after registration shall occupy at least five years. The Final examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

The following is a list of Examining Bodies whose examinations in general education are recognised by the General Medical Council as qualifying for registration as a medical or dental student the applicant producing satisfactory evidence that he has passed them:—

I.—UNIVERSITIES IN THE UNITED KINGDOM.

University of Oxford.—Junior Local Examinations. Senior Local Examinations. Responsions. Moderations. Final Examination for a degree in Arts.

University of Cambridge.—Junior Local Examinations. Senior Local Examinations. Higher Local Examinations. Previous Examination. General Examination. Final Examination for a degree in Arts.

University of Durham.—Examination for Certificate of Proficiency. Preliminary Examination in Arts for Graduation in Medicine and Science. Final Examination for a degree in Arts.

University of London.—Matriculation Examination. Final Examination for a degree in Arts or Science.

Victoria University.—Preliminary Examination. Entrance Examination in Arts. Final Examination for a degree in Arts or Science.

University of Birmingham.—Matriculation Examination.

University of Wales.—Matriculation Examination. Final Examination for a degree in Arts or Science.

University of Edinburgh.—Local Examinations (Senior and Junior). Preliminary Examination for Graduation in Arts or Science or Medicine and Surgery. Final Examination for a degree in Arts or Science.

University of Aberdeen.—Local Examinations (Senior and Junior). Preliminary Examination for Graduation in Arts or Science or Medicine and Surgery. Final Examination for a degree in Arts or Science.

University of Glasgow. — Preliminary Examination for Graduation in Arts or Science or Medicine and Surgery. Final Examination for a degree in Arts or Science.

University of St. Andrews.—Preliminary Examination for Graduation in Arts or Science or Medicine and Surgery. Final Examination for a degree in Arts or Science or for the diploma of L L A.

University of Dublin. — Public Entrance Examination. Examination for the first, second, third, or fourth year in Arts Final Examination for a degree in Arts.

Royal University of Ireland.—Matriculation Examination. Final Examination for a degree in Arts or Science.

Oxford and Cambridge Schools Examination Board.—Lower certificate (to include all the required subjects at one time). Higher certificate (to include the required subjects).

II.—MEDICAL LICENSING BODIES.

Royal Colleges of Physicians and Surgeons in Ireland.—Preliminary Examination.[1]

III —EDUCATIONAL BODIES OTHER THAN UNIVERSITIES.

College of Preceptors.—Examination for a First Class Certificate.

Intermediate Education Board of Ireland.—Junior or Middle Grade Examination; Senior Grade Examination.

Educational Institute of Scotland. — Preliminary Medical Examination.

Scotch Education Department. — Leaving Certificates in Lower and Higher Grades and in Honours.

Central Welsh Board.—Senior Certificate Examination.

IV. — INDIAN, COLONIAL, AND FOREIGN UNIVERSITIES AND COLLEGES.

The Certificates from Indian, Colonial, and Foreign Universities and Colleges must contain evidence that the Examination has been conducted by or under the authority of the Body granting it, must include all the subjects required by the General Medical Council, and must state that all the subjects of Examination have been passed in at one time; copies of the form of the required Certificate are supplied by the Registrar of the Council for the purpose. In the case of Natives of India or other Oriental countries whose vernacular is other than English an Examination in a Classic Oriental Language may be accepted instead of an Examination in Latin.

H. E. Allen, LL.B., Registrar of the General Council and of the Branch Council for England, 299, Oxford-street, London, W.—James Robertson, Registrar of the Branch Council for Scotland, 48, George-square, Edinburgh.—S. W. Wilson, L.R.C.P. Irel., Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin.

POWERS AND DUTIES OF THE GENERAL MEDICAL COUNCIL.

As there is apparently, even among members of the medical profession, a great amount of ignorance as to the powers and duties of the General Medical Council, we think it well to lay clearly before our readers what the General Medical Council is and also what it is not.

Many of the false ideas on the subject are due to the use of the shortened title, "General Medical Council." The full title is, "General Council of Medical Education and Registration of the United Kingdom." This title is in accordance with the Medical Act of 1858, by which the General Medical Council was established to enable persons requiring medical aid to distinguish qualified from unqualified practitioners. Registrars were to be appointed by the General Council and by the Branch Councils to keep registers of qualified persons. Registrars were bound by Section XIV. of the Act to keep their registers correctly, a duty which, mainly owing to the apathy of members of the medical profession, has not been adequately performed.

It will thus be seen that the General Medical Council is primarily a body of gentlemen charged with looking after the education and registration of medical practitioners. The sole penalty it can inflict is to strike a man's name off the

---

[1] The Council has recommended that this examination be discontinued.

Medical Register. It is as well here to put down the advantages, such as they are, of being duly registered. A duly registered practitioner may sue in the courts of law for the recovery of charges for medical attendance or advice, or surgical attendance or advice, or for the supply of medicine, or for the performance of any operation—provided that he is not debarred from suing by being a Fellow or a Member of any corporation which objects to its Fellows or Members so suing. He may be exempted, if he so desire, from serving on juries, from serving sundry corporate and parochial offices, and from serving in the Militia. Only a registered practitioner can hold appointments in the navy, army, and sundry Poor-law and other institutions. Only a registered person can sign a valid medical certificate. Removal of the name from the Register debars a man from all the above-mentioned privileges.

Let us now consider what the General Medical Council is not. Unfavourable comparisons are often drawn between the General Medical Council and the Incorporated Law Society. The two bodies are not in the very least upon the same footing. The Incorporated Law Society is a society composed of such practitioners as apply for membership and are elected by the Council. It is by statute the keeper of the roll of solicitors who have to pay a fee each year to obtain renewal of certificate to practise, which certificate has then to be stamped by the Inland Revenue authorities on payment of the annual duty. The society is also intrusted with the duty of inquiring into professional misconduct and reports thereon to the High Court which may or may not agree with the report. The offender is struck off the rolls by the court, not by the society. Only a minority of solicitors are members of the society. The society has a charter and is governed by a council. The somewhat analogous body in the medical profession is the British Medical Association, which, however, has none of the legal powers possessed by the Incorporated Law Society.

The General Medical Council is in no way a medical protection society or a medical defence union. It is not a professional union or a guild charged with looking after the interests of the medical profession after the manner of the old trades guilds, except in so far as it is concerned with the education of medical students. It has no powers over any member of the medical profession except to remove the name of any offending member from the roll of the profession or Medical Register. It cannot take away any degree, or diploma, or licence, and even if a practitioner is struck off the Medical Register there is nothing in the existing state of the law to prevent such practitioner continuing to practise, provided that he does not use any name or title implying that he is registered. Practitioners may be removed from the Medical Register (1) if convicted of felony or misdemeanour in England or in Ireland, or in Scotland of any crime or offence, and (2) on being adjudged by the General Medical Council to have been guilty of "infamous conduct in a professional respect." The words "infamous conduct" are certainly unfortunate, for they cover such a comparatively trivial offence as advertising, and such a truly infamous offence as that recently committed by a medical man who committed adultery with a married woman whom he was attending professionally.

The General Medical Council is primarily a body charged with looking after medical education; it is but little concerned with medical politics. Inspection of the last volume of the minutes dealing with the period Jan. 1st to June 11th, 1901, shows that the time of the Council was almost entirely taken up with considering educational and registration matters, the latter including the penal cases of removal from the Register. Among other subjects the Council received the note from the Privy Council as to reciprocity in Italy and a report from the Medical Aid Associations Committee relative to the formation of a Conciliation Board. The Council at present consists of 31 members, of whom, as will be seen by the annexed list, all but 10 are representatives of some corporate body. Five members are chosen by the Crown on the advice of the Privy Council, and five others are elected by the members of the medical profession as Direct Representatives. An election takes place this winter to select the Direct Representatives for the next five years.

President of the General Council.—Sir William Turner. Members of the General Council.—Dr. Norman Moore, chosen by the Royal College of Physicians of London; Mr. Thomas Bryant, Royal College of Surgeons of England; Sir Hugh Reeve Beevor, Apothecaries' Society of London; Dr. Joseph Frank Payne, University of Oxford; Dr. Donald MacAlister, University of Cambridge; Sir George Hare Philipson, University of Durham; Dr. Philip Henry Pye-Smith, University of London; Dr. Alfred Harry Young, Victoria University; and Dr. Bertram C. A. Windle, University of Birmingham. Sir John Batty Tuke, chosen by the Royal College of Physicians of Edinburgh; Dr. Patrick Heron Watson, Royal College of Surgeons of Edinburgh; Sir Hector Clare Cameron, Faculty of Physicians and Surgeons of Glasgow; Sir William Turner, University of Edinburgh; Sir William Tennant Gairdner, University of Glasgow; Dr. Robert William Reid, University of Aberdeen; and Dr. James Bell Pettigrew, University of St. Andrews. Dr. Lombe Atthill chosen by the Royal College of Physicians of Ireland: Dr. Charles Bent Ball, Royal College of Surgeons in Ireland; Mr. Charles R. C. Tichborne, Apothecaries' Hall of Ireland; Dr. Edward Hallaran Bennett, University of Dublin; and Sir Christopher John Nixon, Royal University of Ireland. Nominated by His Majesty, with the advice of his Privy Council: Mr. Charles Sissmore Tomes, Mr. William Henry Power, Sir John Williams, Dr. David Caldwell McVail, and Dr. James Little. Elected as Direct Representatives: Mr. George Brown, Dr. James Grey Glover, Mr. Victor Alexander Haden Horsley, Dr. William Bruce, and Sir William Thomson. Treasurers of the General Council.—Mr. Thomas Bryant and Dr. Philip Henry Pye-Smith. Registrar of the General Council and of the Branch Council for England.—Mr. Henry E. Allen, LL.B., B.A. Registrar of the Branch Council for Scotland.—Mr. James Robertson. Registrar of the Branch Council for Ireland.—Mr. S. Wesley Wilson.

REGULATIONS
OF THE
MEDICAL EXAMINING BODIES IN THE UNITED KINGDOM.

UNIVERSITY OF OXFORD.

THERE are two degrees in Medicine, B.M. and D.M., and two degrees in Surgery, B.Ch. and M.Ch.

The B.M. and B.Ch. degrees are granted to those members of the University who have passed the Second Examination. Graduates in Arts (B.A. or M.A.) are alone eligible for these two degrees. In order to obtain the degrees of B.M. and B.Ch. the following examinations must be passed:—1 Preliminary subjects: Mechanics and Physics, Chemistry, Animal Morphology and Botany. 2. Professional. (*a*) First Examination: Subjects—Organic Chemistry, unless the candidate has obtained a first or second class in Chemistry in the Natural Science School; Human Physiology unless he has obtained a first or second class in Animal Physiology in the Natural Science School; Human Anatomy, and Materia Medica with Pharmacy (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology Forensic Medicine with Hygiene. The approximate dates of the examinations are as follows:—Preliminaries—Mechanics, Physics and Chemistry, December and June; Animal Morphology, December and March; Botany, March and June; Professional (First and Second B.M.) June and December.

The degree of D.M. is granted to Bachelors of Medicine of the University—(1) who took the degree of B.M. previously to the end of Trinity Term, 1886, provided they have spent three years in the practice of Medicine after taking that degree, and have composed a dissertation on some medical subject approved by the Regius Professor of Medicine, before whom it must be read in public; (2) who took the degree of B.M. subsequently to the end of Trinity Term, 1886 provided they have entered their thirty-ninth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners for the degree of B.M. whose subject is dealt with. A book published within two years of the candidate's application for the degree may be substituted for a dissertation. The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for six months, and who have passed an examination in Surgery, Surgical Anatomy, and Surgical Operations. This examination is held annually, in June, at the end of the Second B.M Examination.

The First Examination for the degrees of B.M. and B.Ch. may be passed as soon as the Preliminary Scientific Examinations have been completed. The subjects of this examination may be presented separately or in any combination or in any order, provided Anatomy and Physiology be passed together.

The Second Examination may be passed after the completion of the first, but Pathology may be professed before, with, or after the remaining subjects Before admission to the Second Examination candidates must present Certificates of instruction in Infectious and Mental Diseases, and of attendance on Labours, and of proficiency in the practice of Vaccination.

Scholarships, &c.—Scholarships in some branch of Natural Science (Chemistry, Physics, Biology) of the average value of £80 per annum, tenable for four years and renewable under certain conditions for a fifth year, as well as Exhibitions of a less annual value, are awarded after competitive examination every year by some of the Colleges. Notices of vacancy, &c., are published in the *University Gazette*. In February there is competed for annually by those who, having obtained a first-class in any school (Moderations or final), or a Scholarship or Prize open to general competition in the University, have passed all the examinations for the degree of B.M. one Radcliffe Travelling Fellowship. It is tenable for three years and is of the annual value of £200. The examination is partly scientific, partly medical. The holder must travel abroad for the purpose of medical study. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject including Physiology or Pathology.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1894, which contain the official schedules of the several subjects of examination in both Arts and Medicine; from the Student's Handbook to the University, published by the Clarendon Press; from the Regius Professor of Medicine; and from the Professors in the several departments of medical science.

The Lecturers for the various subjects are as follows:—Regius Professor of Medicine: Sir J. S. Burdon-Sanderson, D.M Pathological Histology and Practical Bacteriology: The Lecturer in Pathology, J Ritchie, D.M Edin. Professor of Human Anatomy: A. Thomson, M.A. Waynflete Professor of Physiology: F. Gotch, M.A. University Lecturer on Physiology: J S Haldane, M.A Practical Physiology and Histology: G Mann, D.M. Edin. Physiological Chemistry: Walter Ramsden, M A. Lichfield Lecturer in Clinical Medicine: W. Collier, M A., D.M. Camb. Lichfield Lecturer in Clinical Surgery: Alfred Winkfield, F.R C.S Eng. Organic Chemistry in Relation to Medicine, &c., followed by Practical Work: Aldrichian Demonstrator, W. W. Fisher, M.A., and J. E. Marsh, M A Lecturer in Materia Medica and Pharmacology: W. J. Smith Jerome, B M Lond Linacre Professor of Comparative Anatomy. W. F. R Weldon, M.A Elementary Animal Morphology (Practical): the Aldrichian Demonstrator, E. Goodrich, M.A., and assistants. Sherardian Professor of Botany: S. H. Vines, M.A Waynflete Professor of Chemistry: W. Odling, M.A Lees Reader in Chemistry: A G Vernon Harcourt, M.A. Laboratory Instruction: W. W. Fisher, M.A. J. Watts, M.A., V. H. Veley M.A., and J E. Marsh, M.A. Professor of Experimental Philosophy: R. B Clifton, M.A. Instruction in Practical Physics: R. B. Clifton, M.A., J. Walker, M.A., and J. C. Alsop, B.A. Elementary Heat and Light: Lees Reader in Physics, R E. Baynes, M.A. Elementary Mechanics: F. J. Smith, M.A

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms by residence in the University. He must pass the Previous Examination in Classics Mathematics, &c, which may, and should if possible, be done before coming into residence in October, or he may obtain exemption through the Oxford and Cambridge Schools Examination Board or the Cambridge Senior Local Examinations. He may then devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts, either continuing mathematical and classical study and passing the ordinary examinations for B.A., or going out in one of the Honour Triposes. The Natural Sciences Tripos is the most appropriate, as some of the subjects are practically the same as those for the first and second M.B. examinations.

For the degree of *Bachelor of Medicine (M.B.)* five years of medical study are required. This time may be spent in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge, the student remaining in the University till he has passed, say, the examination for the Natural Sciences Tripos and the first and second examinations for M.B. Cambridge being now a complete School of Medicine, all the requisite lectures and hospital practice may be attended here, and many students remain to attend lectures and hospital practice until they have passed the first part of the third examination for M B. The supply of subjects for Dissection is abundant and the laboratories for Pathology, Bacteriology, and Pharmacology are well equipped. Addenbrooke's Hospital provides for the necessary clinical training.

There are three examinations for M.B The *first* includes Chemistry and other branches of Physics, and Elementary Biology. These parts may be taken together or separately. The *second* includes Human Anatomy and Physiology. The *third* is divided into two parts—viz, (1) Pharmacology and General Pathology; (2) Principles and Practice of Surgery, Midwifery and Diseases peculiar to Women, Principles and Practice of Physic. The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting-room, and in the laboratories. An Act has then to be kept in the Public Schools, by the candidate reading an original dissertation composed by himself on some subject approved by the Regius Professor of Physic.

As Operative and Clinical Surgery now form parts of t third M.B. examination candidates who have passed bo parts of that examination are admitted to the registra degree of *Bachelor of Surgery (B.C.)* without separa examination and without keeping an Act.

The degree of *Doctor of Medicine* may be taken thr years after that of M.B. or four years after that of M. An Act has to be kept, consisting of an original The sustained in the Public Schools, with *vivâ voce* examinatio and an extempore Essay has to be written on some subj relating to Physiology, Pathology, the Practice of Medici or State Medicine.

For the degree of *Master of Surgery (M.C.)* the candid must have passed all the examinations for B C., if he is an M.A. have obtained some other registra qualification in surgery. He is required either (1) pass an examination in Surgical Anatomy and Surgi Operations, Pathology, and the Principles and Pract of Surgery, and to write an extempore Essay a Surgical Subject; or (2) to submit to the Medi Board original contributions to the advancement of Science or Art of Surgery. Before he can be admitted to examination two years at least must have elapsed fr the time when he completed all required for the degree B.C. Before submitting original contributions he must h been qualified at least three years.

An abstract of the Regulations and Schedules of the ra of the examinations in Chemistry, Physics, Biology, a Pharmaceutical Chemistry may be obtained upon sendi a stamped directed envelope to the Registrary, Cambrid Full information is contained in the *Cambridge Univers Calendar*.

UNIVERSITY OF LONDON.

The Matriculation Examination.—Candidates for a degree in this University must have passed the Matricu t on Examination. No exemption either from Matriculati or from subsequent examinations is allowed on account degrees obtained at other Universities or of examinatio of other examining bodies that may have been passed. T examinations take place twice in each year—on the seco Monday in January and the second Monday in June; a may be held not only at the University of London, but als under special arrangement, in other parts of the Unit Kingdom or in the colonies. Every candidate must, on before April 25th for the June examination, and on or befo

Nov. 25th for the January examination, apply to the Registrar for a form of entry, which must be returned on or before May 1st or Dec. 1st respectively, accompanied by a certificate showing that the candidate has completed his sixteenth year and by his fee for the examination. A certificate from the Registrar General in London or from the superintendent registrar of the district, or a certified copy of the baptismal register, is required in every case in which it can possibly be obtained. In other cases a declaration [illegible] ade before a magistrate by his par[illegible] candidate, if of full age, will be [illegible] cannot be admitted after the list is closed, any candidate who may not have received a form of entry within a week after applying for it should communicate immediately with the Registrar, stating the exact date of his application and the place where it was posted. Every candidate must pay a fee of £2, and if he withdraws his name, or fails to present himself at the examination, or fails to pass it, the fee shall not be returned to him, but he shall be allowed to enter for any subsequent matriculation examination upon payment at every such entry of an additional fee of £1, provided that he comply with the other regulations. Candidates must show a competent knowledge of: 1. Latin 2. English Language, History to the end of the seventeenth century, with the Geography relating thereto. 3 Mathematics (Elementary) 4. General Elementary Science. 5 Any one of the following languages or sciences: Greek, French, German, Sanskrit, Arabic, Elementary Mechanics, Elementary Chemistry, Elementary Sound, Heat, and Light Elementary Magnetism and Electricity, and Elementary Botany. (No credit will be given for more than one of these subjects, and candidates desiring to be examined in Sanskrit or Arabic must give two months' notice to the Registrar. The examination in Botany is only held in the United Kingdom. Candidates in any one of the optional Branches of Science will find it an advantage to have obtained some elementary instruction in the practical use of apparatus) A pass certificate signed by the Registrar is delivered to each successful candidate after the report of the examiners shall have been approved by the Senate. The first six candidates in the Honours Division, of not more than twenty years of age at the commencement of the examination, shall respectively receive an exhibition or a prize. Any candidate obtaining a place in the Honours Division at the matriculation examination in January shall be admissible to the intermediate examination either in Arts or in Science in the following July

Provincial Examinations for Matriculation.—These examinations are appointed by the Senate from time to time upon the application of any city, institution, or college desiring to be named as a local centre for one or more examinations, and are carried on simultaneously with the examinations in London under the supervision of sub-examiners also appointed by the Senate. Candidates wishing to be examined at any provincial centre must give notice upon their forms of entry to the Registrar of the University, who will then make all necessary arrangements. Besides the University fee, a fee usually varying from £1 to £2 is charged by the local authorities, and must be paid *at the local centre* immediately before the commencement of the several examinations The answers of the candidates at the provincial examinations are reviewed by the examiners at the same time as the answers of the candidates examined in London, and a list of the candidates who have passed at each provincial examination is published, at the time fixed by the regulations, at the place where such examination has been held.

Preliminary Scientific [illegible] studies pursued before the whc[illegible] as been passed will not coun[illegible] required for the M B degree Candidates must have passed the matriculation examination. The examination takes place twice in each year, once for Pass and Honours, commencing on the second Monday in July, and once for Pass candidates only, commencing on the third Monday in January Every candidate must apply by post-card to the Registrar for a form of entry on or before May 24th for the July examination, or on or before Dec. 15th for the January examination, which must be returned on or before June 1st and Dec 22nd respectively, accompanied by the candidate's fee of £5 The subjects [illegible] divide[illegible] General [illegible] In Che[illegible] and Simple Volumetric Analysis. Physics implies a knowledge of acoustics, heat, magnetism, electricity, and optics. General Biology comprises a knowledge of the elements of zoological (vertebrate or invertebrate) and botanical morphology, physiology, and embryology. Candidates shall be allowed to enter for the whole examination or for either section. Candidates who present themselves for the two sections together shall be credited with either section in which they may have passed, although they may have failed to pass in the other, but no such candidate shall be placed in the Honours List. Candidates must bear in mind that the standard of attainment for the Honours examination is much higher than that for the Pass examination; and they should therefore exercise due caution in making their choice, to which they will be required to adhere. Candidates for Honours in Botany and Zoology must take the Pass examination in General Biology; in other respects no candidate may take both the Pass and the Honours papers in the same subject. The fee of £5 covers the whole of the examination, whether taken altogether or in sections

Provincial Examinations for the Preliminary Scientific Examination —The pass examination (except the practical examinations) may be held not only at the University of London but also under special arrangements in other parts of the United Kingdom. All Honours papers, some of which under former arrangements used to be given out at the provincial centres, must now be taken only at the University of London.

Bachelor of Medicine —Every candidate for the degree of Bachelor of Medicine will be required—1 To have passed the Matriculation Examination in this University not less than five years previously. 2. To have passed the Preliminary Scientific Examination not less than four years previously. 3 To have been engaged in his professional studies during five years subsequent to matriculation and four years subsequent to passing the Preliminary Scientific Examination at one or more of the medical institutions or schools recognised by this University, one year at least of the four being spent in one or more of the recognised institutions or schools in the United Kingdom. 4. To pass two examinations in Medicine

Intermediate Examination —The Intermediate Examination in Medicine takes place twice in each year—once for Pass and Honours commencing on the first Monday in July, and once for Pass candidates only, commencing on the third Monday in January The subjects of the examination are Anatomy, Physiology and Histology, Organic Chemistry, Materia Medica, and Pharmaceutical Chemistry. The standard of attainment required for Honours is much higher than for a Pass No candidate shall be admitted to this examination unless he have passed the Preliminary Scientific Examination at least two years previously and have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2 Of having, subsequently to having passed the Preliminary Scientific Examination, been a student during two years at one or more of the medical institutions or schools recognised by this University, and of having attended a course of lectures on each of three of the subjects in the following list: Descriptive and Surgical Anatomy, Physiology and Histology, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases Peculiar to Women and Infants, Surgery, Medicine 3. Of having, subsequently to having passed the Preliminary Scientific Examination, *dissected during two sessions.* 4 Of having, subsequently to having passed the Preliminary Scientific Examination, attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of general and pharmaceutical chemistry, in applying tests for discovering the adulteration of articles of the Materia Medica and the presence and nature of poisons, and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c 5 Of having attended to Practical Pharmacy and of having acquired a practical knowledge of the preparation of medicines These certificates (as is the case also with all the certificates hereinafter mentioned) must be transmitted to the Registrar at least four weeks before the commencement of the examination. Fee for this examination, £5

M B. Examination —The M B Examination takes place twice in each year—once for Pass and Honours, commencing on the last Monday in October, and once for Pass candidates only, commencing on the first Monday in May. The subjects of the examination are General Pathology, General Therapeutics, Hygiene, Surgery, Medicine, Obstetric Medicine, and Forensic Medicine. No candidate will be admitted to this examination within twenty-one months of the time of his passing the Intermediate Examination unless he be a registered medical practitioner of not less than three years' standing, in which case he must produce certificates of having gone through the required course of training at any time previously. Every candidate must produce certificates:—1. Of having passed the Intermediate Examination. 2. Of having attended a course of lectures on each of two of the subjects enumerated above in the regulations for that examination for which the candidate had not on that occasion presented certificates. 3. Of having conducted at least twenty labours. Certificates on this subject will be received from any legally qualified practitioner in Medicine. 4. Of having attended the Surgical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Surgery. 5. Of having attended the Medical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Medicine, including Infectious Diseases and Lunacy. 6. Of having, after having attended Surgical and Medical Hospital Practice for at least twelve months subsequently to passing the Intermediate Examination in Medicine, attended to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union during six months, such attendance not to be counted as part of either the Surgical or the Medical Hospital Practice prescribed in Clauses 4 and 5. 7. Of having acquired proficiency in Vaccination. Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council. The fee for this examination is £5.

Bachelor of Surgery.—The examination for the degree of Bachelor of Surgery takes place once in each year and commences on the Tuesday following the first Monday in December. Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in Operative Surgery and of having operated on the dead subject. The subjects of the examination are Surgery and Pathology and Surgical Anatomy. Fee £5.

Master in Surgery.—The examination for the degree of Master in Surgery takes place once in each year and commences on the first Monday in December. Candidates must produce certificates to the following effect:—1. Of having taken the degree of Bachelor of Surgery in this University. 2 Of having attended, subsequently to having taken the degree of Bachelor of Surgery in this University: (*a*) to Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University; or (*b*) to Clinical or Practical Surgery during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; or (*c*) of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University. One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B.S. Examination have been placed in the first division. 3 Of moral character, signed by two persons of respectability. The examination is conducted by means of printed papers and *vivâ voce* interrogation, and the subjects are Mental Physiology (especially in its relations to mental disorder) and Surgery. Any candidate for the degree of M.S. may transmit to the Registrar, not later than Oct. 1st, a printed Dissertation, Thesis, or Commentary, written in view of candidature, or published within two academical years immediately preceding, treating scientifically some special department of Surgical Science; and if the Thesis be approved by the examiners the candidate will be exempt from the written examination in Surgery. The fee is £5.

Doctor of Medicine.—The examination for this degree takes place once in each year and commences on the first Monday in December. Candidates may present themselves for examination either in Medicine or State Medicine. Those presenting themselves for the M.D. Examination in Medicine must produce certificates to the following effect:—1. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this University: (*a*) to Clinical or Practical Medicine during two years in a hospital or medical institution recognised by this University; (*b*) or to Clinical or Practical Medicine during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of their profession; (*c*) or of having been engaged during five years in the practice of their profession, either before or after taking the degree of Bachelor of Medicine in this University. 2. Of moral character, signed by two persons of respectability. One year of attendance on Clinical or Practical Medicine, or two years of practice, will be dispensed with in the case of those candidates who at the M.B. Examination have been placed in the First Division. Candidates presenting themselves for the M.D. Examination in State Medicine must produce certificates to the following effect:—1. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this university: (*a*) to State Medicine during two years, including six months' practical instruction in a laboratory and six months' outdoor sanitary work; (*b*) or to State Medicine during one year, and of having held for a period of two years the position of medical officer of health in any sanitary district; (*c*) or of having held for a period of three years the position of medical officer of health in any sanitary district. 2. Of moral character. One year of attendance on State Medicine or one year of holding the position of medical officer of health will be dispensed with in the case of those candidates who at the M.B. Examination have been placed in the First Division. The examination is conducted by means of printed papers and *vivâ-voce* interrogation, and the subjects are Medicine (or State Medicine) and Mental Physiology (especially in its relation to mental disorder). Any candidate for the degree of M.D. may transmit to the Registrar, not later than Oct. 1st, a printed Thesis, written in view of candidature, or published within two academical years immediately preceding, treating scientifically some special department of Medical Science; and if the Thesis be approved by the examiners the candidate will be exempt from the written examination in Medicine (or State Medicine). The fee is £5.

UNIVERSITY OF DURHAM.

One Diploma and six degrees are conferred—viz., the Diploma in Public Health and the degrees of Bachelor in Medicine, Bachelor in Surgery, Master in Surgery, Doctor in Medicine, Bachelor in Hygiene, and Doctor in Hygiene. These degrees are open both to Men and Women.

For the degree of *Bachelor in Medicine* (*M.B.*) there are four professional examinations

The subjects of the First Examination are—Elementary Anatomy and Elementary Biology, Chemistry, and Physics.

The subjects for the Second Examination are—Anatomy, Physiology, Materia Medica, Therapeutics, Pharmacology, Pharmacy.

The subjects for the Third Examination are—Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology.

The subjects of the Fourth Examination are—Medicine, Clinical Medicine and Psychological Medicine, Surgery and Clinical Surgery, Midwifery and Diseases of Women and Children:

N.B —It is required that at least one of the five years of professional education shall be spent in attendance at the University College of Medicine, Newcastle-upon-Tyne. Candidates who have passed the First and Second Examinations of the University will be exempt from First and Second Examinations of the Conjoint Board.

For the degree of *Bachelor in Surgery* (*B.S.*) every candidate must have passed the examination for the degree of Bachelor in Medicine of the University of Durham and must have attended one course of lectures on Operative Surgery and one course on Regional Anatomy. Candidates will be required to perform operations on the dead body and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of *Master in Surgery* (*M.S.*) candidates must not be less than twenty-four years of age and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M.B degree they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor in Surgery of the University of Durham and must have been engaged for at least two years subsequent to the date of acquirement of the degree of Bachelor in Surgery, in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice.

The subjects of examination are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

For the degree of *Doctor in Medicine (M.D.)* candidates must be not less than twenty-four years of age and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M.B. degree they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor in Medicine of the University of Durham and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Medicine in attendance on the practice of a recognised hospital, or in the military or naval services, or in medical and surgical practice. Each candidate must prepare an Essay, which must be typewritten, based on original research or observation, on some medical subject selected by himself, and approved of by the Professor of Medicine and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum so far as they are related to the subject of the Essay.

The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates shall not be under 40 years of age and shall have been in active practice for 15 years as registered medical practitioners. They shall produce certificates of moral character from three registered members of the medical profession, and if they have not passed an examination in Arts previously to the Professional Examination in virtue of which they have been placed on the Register, they shall be required to pass in Classics and Mathematics. Candidates who have passed an examination in Arts previously to being placed on the Register are required to pass an examination in Latin. They will be examined in the Principles and Practice of Medicine, including Psychological Medicine, Hygiene, and Therapeutics, the Principles and Practice of Surgery, Midwifery, and Diseases of Women and Children, Pathology (Medical and Surgical), Anatomy (Medical and Surgical), Medical Jurisprudence, and Toxicology. The fee will be 50 guineas, of which 20 guineas will be retained if the candidate fails to satisfy the examiners.

Candidates for any of the above degrees must give at least 28 days' notice to Professor Howden, Secretary, College of Medicine, Newcastle-on-Tyne.

VICTORIA UNIVERSITY (MANCHESTER).

Colleges of the University: Owens College, Manchester; University College, Liverpool; and Yorkshire College, Leeds.

Matriculation, which consists in signing the University Register, must precede entry upon any course of study in a College of the University, if that course is to be counted towards the required minimum of attendance for a degree. Those only can matriculate who are registered students of a College of the University.

Four degrees in Medicine and Surgery are conferred by the Victoria University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.).

All candidates for degrees in Medicine and Surgery are required to pass an examination called the Preliminary Examination (Faculty of Medicine), or to have passed s other examination as may be recognised by the Univer for this purpose.[2]

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation and that they have pursued the courses of study required by the University Regulations during a period of not less than five years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in a College of the University, and one year at least having been passed in a College of the University subsequently to the date of passing the First M.B. Examination. All candidates for the degrees of Bachelor of Medicine and Bachelor of Surgery are required to satisfy the examiners in the several subjects of the following examinations: the First Examination, the Second Examination, and the Final Examination.

The First Examination.—The subjects of examination are as follows:—(1) Chemistry; (2) Elementary Biology; (3) Physics. Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into two parts: Part 1, Physics and Chemistry; Part 2, Biology; and the candidates may pass in these parts separately.

The Second Examination.—The subjects of examination are as follows:—A: (1) Anatomy; (2) Physiology, including Physiological Chemistry and Histology; B: (3) Materia Medica and Pharmacy. Candidates may pass in A or B separately.

The Final Examination.—The subjects of examination are as follows:—(1) Pharmacology and Therapeutics. (2) General Pathology and Morbid Anatomy. (3) Forensic Medicine and Toxicology, and Public Health. (4) Obstetrics and Diseases of Women. (5) Surgery, Systematic, Clinical and Practical. (6) Medicine, Systematic and Clinical, including Mental Diseases and Diseases of Children.

Candidates may either present themselves in all the six subjects of examination on the same occasion or may pass the examination in two parts, the first part consisting of *two* or *three* of the subjects (1), (2) and 3), the second part of the remaining subjects.

Candidates who fail to satisfy the examiners in the first part must either present themselves again in the subjects as selected or in all the three subjects of the First part or in all the six subjects of examination.

Candidates for the first part of the examination must have completed the *fourth winter* of medical study.

Candidates for the second part of the examination, or for the whole examination, must have completed the fifth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine are required to present a printed Dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine. No candidate will be admitted to the degree unless his Dissertation shall have been recommended by the General Board of Studies to the Council for acceptance. Candidates may be examined on any subject connected with their dissertations.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and

---

[2] The examinations at present recognised are:—1. Graduatio this or some other university of the United Kingdom, provided Latin has formed part of one of the Degree Examinations. 2. Lor Matriculation. 3. Higher Certificate of the Oxford and Cambr hchools Examination Board. (Certificates must show that the ca date has satisfied the Examiners in Latin, Elementary and Additional Mathematics, English or History, and in either Greek, French, or German. The Mechanical Division of Natural Philosophy will satisfy [illegible] Locals (Honours). [illegible] power to accept other examinations of at least equal standard.

Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The subjects of examination are as follows: (1) Surgical Anatomy; (2) Surgery; (3) Operative Surgery; (4) Clinical Surgery; (5) Ophthalmology; (6) Pathology and Bacteriology.

Communications should be addressed to the Registrar, Victoria University, Manchester.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., B.Ch., M.D., M.Ch., and also a B.Sc., and a degree and a diploma in Public Health. In order to obtain any of these degrees it is necessary that a student shall have passed at least the first four years of his curriculum in attendance upon the classes of the University.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed either the Matriculation Examination of the University or one of the following examinations, which will be accepted in lieu thereof, for the present: (*a*) the previous examination of the University of Cambridge; (*b*) responsions of the University of Oxford; (*c*) the Matriculation Examination of any other University in the United Kingdom; (*d*) the leaving Certificate (Higher) of the Oxford and Cambridge Boards; (*e*) the Oxford or Cambridge Junior Local Examinations (First or Second Class Honours); (*f*) the Oxford or Cambridge Senior Local Examination (Honours); or (*g*) the College of Preceptors' Examination for First Class Certificate A Matriculation Examination will be held on Sept. 16th, 1901, and succeeding days. First Examination.—Chemistry and Physics. Second Examination.—Anatomy, Comparative Anatomy, and Physiology. Third Examination.—Materia Medica and Pharmacy. Fourth Examination (at the end of the fourth year).—Pharmacology, Pathology, Forensic Medicine, Toxicology, and Public Health. Two years' hospital work must have been accomplished Final Examination.—Medicine, Surgery, Midwifery, Gynæcology, Mental Diseases, and Ophthalmology. Attendance on general hospital for a year after the passing of the fourth examination, also attendance at fever hospital, lunatic asylum, vaccination, and courses of Ophthalmology, Medical and Surgical Anatomy and Operative Surgery.

Degrees of Doctor of Medicine and Master of Surgery.—Candidates for either of these degrees will be required either (*a*) to present a thesis embodying original observations in some subject embraced in the medical curriculum and approved by a board of medical examiners to whom the thesis will subsequently be submitted, on the report of which board the degree will be awarded or withheld (the candidate may be examined on the subject which he has chosen for his thesis and the examiners may require to see the notes of original observations on which the thesis is based); or (*b*) to pass a general examination (written and practical) in Medicine or Surgery, according to the degree desired, and, in addition, to show special proficiency in any one of the following subjects to be chosen by the candidate. For the degree of M.D.: (*a*) Infectious Diseases, (*b*) Diseases of the Chest. (*c*) Diseases of the Abdomen, (*d*) Nervous Diseases, (*e*) Diseases of Children, (*f*) Midwifery, (*g*) Pathology, (*h*) Bacteriology, (*i*) Medical Jurisprudence and Toxicology, (*j*) Public Health, (*k*) Mental Diseases, or (*l*) Diseases of the Skin. For the degree of M.Ch.: (*a*) Regional Surgery, (*b*) Gynæcology, (*c*) Ophthalmology, or (*d*) Diseases of the Ear, Nose, and Throat.

Degree in Public Health.—For the regulations for this degree and for the diploma in the same subject see p. 686.

Fees.—Matriculation, £2; First Examination, £5; Second Examination, £5; Third Examination, £1; Fourth Examination, £3; Final Examination, £5.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degree of Bachelor of Surgery cannot be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and similarly the degree of Bachelor of Medicine is not conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery.

Subject to regulations to be made from time to time by the University Court, the University may also confer diplomas in special branches of medical and surgical practice on graduates of the University in Medicine and Surgery.

Before commencing his medical studies each student must pass a preliminary examination in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek or French or German: Provided always that, in the case of a candidate whose native language is not English, an examination in the native language of the candidate may be substituted for one in either French or German, and an examination in any other classical language for one in Latin or Greek.

No one is admitted to the degrees of Bachelor of Medicine and Bachelor of Surgery who has not been engaged in Medical and Surgical study for five years. No course of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least 100 lectures, or 50 lectures, as may be required by the regulations, and that the student has also duly performed the work of the class.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended Clinical Surgery during a course or courses extending over not less than nine months. These courses may be conducted by the professor of clinical surgery, or by professors or lecturers appointed for the purpose by the University Court, or by the ordinary surgeons of the Royal Infirmary, Edinburgh, or of a general hospital defined and recognised as hereinbefore provided, and shall consist of regular instruction at the bedside, along with clinical lectures. A similar course of clinical medicine during a course or courses extending over not less than nine months is required. The candidate must have attended a course of instruction in Mental Diseases given by the University Lecturer, or by a recognised Teacher, consisting of not less than six Class-room meetings for lectures and demonstrations and ten meetings in the Wards of a recognised Asylum for the insane. The candidate must have attended a course of 25 meetings on Practical Pharmacy in a university or recognised school of medicine, or have dispensed drugs for a period of three months in a hospital or dispensary, or in an establishment recognised by the Pharmaceutical Society. The candidate must have attended for at least six months, by apprenticeship or otherwise, the out-practice of a hospital, or the practice of a dispensary, or of a physician or surgeon, or of a member of the London or Dublin Society of Apothecaries. He must have acted as clerk in the medical wards and dresser in the surgical wards of a public hospital for a period of six months in each case; and must also have availed himself, to such an extent as may be required by the Senatus, with the approval of the University Court, of opportunities of studying at a hospital or dispensary, Post-mortem Examinations, Fevers, Diseases of the Eye, Operative Surgery, and *one of* the three following, viz.—Diseases of Children, and Diseases of the Larynx, Ear, and Nose, and Diseases of the Skin, or such other special departments as may from time to time be determined. The candidate must have attended, under the superintendence of a registered medical practitioner, twelve cases of labour, or such additional number as the Senatus, with the sanction of the University Court, may from time to time determine; or have attended for three months the practice of a lying-in hospital, or of the maternity department of a general hospital or other public charitable institution, and have conducted personally six or such an additional number of cases of labour as the Senatus, with the approval of the University Court, may from time to time determine. The candidate must have been properly instructed in Vaccination at a public vaccination station, by a public vaccinator, authorised by the proper Government authority to grant certificates of proficiency in vaccination.

Next, with respect to the places and institutions at which the studies of the candidate may be prosecuted, the following regulations have effect:—Two of the five years of medical study must be spent in the University of Edinburgh. The remaining three years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign university recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Of the subjects of study, 16 in number—viz., Anatomy, Practical Anatomy, Chemistry Practical Chemistry, Materia Medica, Physiology, Practical Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women, Pathology, Practical Pathology, Physics, Botany, Zoology, Medical Jurisprudence, and Public Health—not less than eight must be taken in the University of Edinburgh or in some other university of the United Kingdom, or in some Foreign or Colonial university entitled to confer the degree of Doctor of Medicine, recognised for the purpose by the University Court, or in a college incorporated with, or affiliated to, a university entitled to confer the degree of Doctor of Medicine, recognised for the purpose by the University Court.

Each candidate is examined, both in writing and orally, *and clinically where the nature of the subject admits*:—*First*, in Chemistry, Zoology, Botany, and Physics; second, in Anatomy, Physiology, Materia Medica, and Therapeutics; third, in Pathology; and fourth in Surgery, Medicine, Midwifery, Forensic Medicine, and Public Health, and clinically in Medicine and Surgery in a hospital. The examinations are conducted, as far as possible, by demonstrations of objects placed before the candidates. Candidates who profess themselves ready to submit to an examination in the first division of these subjects may be admitted to examination therein at the first period of examination after they have completed their attendance on the necessary classes Candidates who have passed their examination in the first division of these subjects may be admitted to examination in the second division at the end of their third winter session Candidates who have passed their examinations in the subjects comprised in the first and second divisions may be admitted to examination in the third division at the end of the fourth winter session. Candidates who have passed their examinations in the subjects comprised in the first, second, and third divisions may be admitted to examination in the fourth or final division when they have completed the fifth year of study.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £23 2*s*., and the proportion of this sum to be paid by a candidate at each division of the examination shall be as follows—viz: For the First Division of the Examination (Botany, Zoology, Physics, and Chemistry), £6 6*s*.; for the Second Division (Anatomy, Physiology, and Materia Medica and Therapeutics), £6 6*s*.; for the Third Division (Pathology), £4 4*s*.; and for the Final [illegible] al Surgery, Medicine and Clinic [illegible] Forensic Medicine and Public [illegible] be paid for the degree of Doctor of Medicine is £10 10*s*., and the fee to be paid for the degree of Master of Surgery is £10 10*s*.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but eight of the subjects other than clinical must be taken in this or some other recognised university entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Under the new regulations four degrees, open both to men and women, are conferred: M.B. and Ch.B (always conjointly), M.D. and Ch.M. A Preliminary Examination must be passed in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek, or French, or German, with possible options to students whose native language is not English in the case of the fourth subject Candidates taking the University preliminary examination are not obliged to pass in all the four subjects at one examination but must do so at not more than two occasions. For the degrees of M.B. and Ch.B. a curriculum of five years is required, in each of the first four of which the student must attend at least two five months' courses, or alternatively one five months' course and two courses of two and a half months. The minimum of attendance in the first four years includes five months' courses in the following subjects:—Anatomy, Practical Anatomy (two courses), Chemistry, Materia Medica and Therapeutics. Physiology. Practice of Medicine, Surgery, Midwifery and Diseases of Women and Infants, and Pathology; and courses of two and a half months in the following:—Practical Chemistry, Physics, Botany, Zoology, Practical Physiology, Practical Pathology, Medical Jurisprudence and Public Health. Candidates must attend at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted as clerk in medical and dresser in surgical wards, and must have had six months' out-door practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 12 cases of labour, or three months of the practice of a Lying-in Hospital, six cases being personally conducted. The University also requires further study in Post-Mortem Examinations, Fevers, and Ophthalmology, and recommends study in other special subjects. If a candidate has completed in a University of the United Kingdom a course of study and passed an examination in Botany, Zoology, Physics or Chemistry, qualifying for a degree in Science or in Arts, he is held to have passed the examinations in such subject or subjects.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry, to be taken after the completion of the included courses (candidates being at liberty to take two subjects at a time); the second comprising Anatomy, Physiology, and Materia Medica and Therapeutics, to be taken at the end of the third winter session; the third comprising Pathology, Medical Jurisprudence and Public Health, to be taken at the end of the fourth winter session; and the fourth or final, comprising Surgery, Clinical Surgery, Practice of Medicine, Clinical Medicine, and Midwifery, to be taken on completion of the fifth year of study.

The degrees of M.D (Doctor of Medicine) and Ch.M. (Master of Surgery) are higher degrees in Medicine and Surgery respectively, and candidates (not under 24 years of age) who have previously obtained the double bachelorship may be admitted to either M.D. or Ch.M. on completing the after course prescribed, including an examination in Clinical Medicine for M.D. and an examination in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M.

Fees.—The fees for M.B. and Ch.B. are £23 2*s*. The class fee in each subject of the curriculum for M.B. and Ch.B. is £3 3*s*. and the present fees for hospital attendance are £21 The fee for M.D. is £10 10*s*. (stamp duty being now abolished), and for Ch.M. £10 10*s*.

During last academic year there were 600 men and 62 women attending University courses in the Faculty of Medicine—a total of 684. The great majority of the students take their hospital course at the Western Infirmary, where clinical instruction is given by professors of the University and other physicians and surgeons. Clinical instruction on Fevers is given at Belvidere Hospital, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Eye, the Ear, the Throat and Nose, and Insanity. Queen Margaret College, hitherto conducted as a separate institution for the higher education of women, has now been made over to the University, and in it medical classes for women are conducted under University professors and other lecturers appointed by the University Court, whilst for clinical instruction female students are admitted to the Royal Infirmary. Since 1894, the year in which the University first conferred degrees on women, 63 women have graduated in Medicine.

Bursaries and Prizes to the annual amount of about £820 are appropriated to medical students, and Scholarships and Fellowships to the annual amount of about £1600 may be held by medical students who have gone through the Arts course.

UNIVERSITY OF ABERDEEN.

The curricula for the several degrees conferred are nearly the same as in the Universities of Edinburgh and Glasgow.

Professional Examinations are held twice in each year—namely, in March and July, directly after the close of the winter and summer sessions.

The fees for graduation are the same as in the University of Edinburgh. Matriculation fee, including all dues, for the winter and summer sessions, £1 1*s.*; summer session alone, 10*s.* 6*d.*

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: General Fever Hospital; Sick Children's Hospital; General Dispensary, and Lying-in and Vaccine Institutions daily; Royal Lunatic Asylum; Eye Institution, in which is given clinical instruction on Diseases of the Eye, and on the application of the Ophthalmoscope for their diagnosis.

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination. The diploma can be entered on the Register of the General Medical Council.

[Application for further information should be addressed to the Secretary of the Medical Faculty.

UNIVERSITY OF ST. ANDREWS (UNITED COLLEGE ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE).

The following are extracts from the Regulations for Degrees in Medicine contained in Ordinance No. 45 (St. Andrews, No. 4) of the Commissioners under the Universities (Scotland) Act, 1889. These regulations came into force on April 19th, 1897. Four Degrees in Medicine and Surgery shall be conferred by the University of St. Andrews—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degrees of M.B. and Ch.B. shall always be conjoined. Before commencing his medical studies each student shall pass a Preliminary Examination in, (*a*) English, (*b*) Latin, (*c*) Elementary Mathematics, and (*d*) one of the following optional subjects:—(α) Greek, (β) French, (γ) German, (δ) Italian, (ε) any other Modern Language, (ζ) Logic. A degree in Arts or in Science in any of the universities of the United Kingdom and in some colonial or foreign universities shall exempt from the Preliminary Examination. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science and the final examination for the Diploma of L.L A

Candidates for the degree of Bachelor of Medicine and Bachelor of Surgery must have been engaged in medical study for at least five years. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz.: Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology, Practical Chemistry, Physics (including the Dynamics of Solids, Liquids and Gases, and the Rudiments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons and is recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery (12 cases of labour), Vaccination, Children's Diseases, Fevers, Ophthalmology, and Post-mortem Examinations

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court.

Women shall be admitted to graduation in Medicine, subject to the provisions of Ordinance No. 18 [General No. 9—Regulations for the Graduation of Women and for their Instruction in the Universities]: Provided always that every candidate for graduation shall produce evidence of having satisfied the conditions herein laid down with respect to the Preliminary Examination, and shall be examined in all the subjects necessary for graduation by the Examiners of the University of St. Andrews. All the classes necessary for graduation shall be taken in the University of St. Andrews, except in so far as instruction obtained elsewhere is allowed by the said Ordinance.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate shall be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., First, in Botany, Zoology, Physics, and Chemistry; Second, in Anatomy, Physiology, and Materia Medica; Third, in Pathology, and Forensic Medicine and Public Health; Fourth, in Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 22 guineas, and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court. The fee to be paid for the degree of Doctor of Medicine shall be 10 guineas, exclusive of any stamp duty which for the time may be exigible. The fee to be paid for the degree of Master of Surgery shall be 10 guineas.

The whole medical curriculum can be taken in University College or the first two years in United College.

Bursaries, United College, St. Andrews.—Fourteen Taylour Thomson Bursaries for female Medical students of the annual value of from £20 to £30 each, tenable for one or two years. The Bursaries are awarded in the order of merit, the most valuable ones being given to those students who obtain the highest marks in the Preliminary Examination, and who are prepared to take two Anni Medici at the United College, St. Andrews.

University College, Dundee.—(*a*) Open to either sex: Eleven Entrance Bursaries of £15, tenable for one year. (*b*) Open to either sex: Four £20 and three £15, second year. (*c*) Four £20 and two £15, third year. (*d*) Bute Bursary, founded in 1893 by the Most Honourable the Marquis of Bute, K.T. This Bursary consists of the free proceeds of £1000. (*e*) Two Bursaries of the annual value of £25, tenable for three years at either University College, Dundee, or at any Scottish University (local candidates only).

For further particulars apply to the Dean of the Medical Faculty, University College, Dundee, N.B.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE).

Matriculation.—All students in the School of Physic intending to practise Physic must be matriculated, for which a fee of 5*s.* is payable. No student can be admitted for the winter course after Nov. 25th.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of matriculation. The Arts course may be concurrent with the medical course, and the B.A. degree need not be taken before the final medical examination, but the medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures—Systematic, Practical and Applied Anatomy, Chemistry and Practical Chemistry, Surgery and Operative Surgery, Histology, Botany, Zoology, Physics, Physiology, Practice of Medicine, Midwifery, Pathology, Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene; (2) three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Dublin Hospital (one year at a recognised London or Edinburgh hospital before the commencement of the Dublin curriculum may be counted as one year spent in such Dublin hospital); (3) Practical Vaccination, one month's instruction; (4) Mental

Disease, three months'; (5) Practical Midwifery with Clinical Lectures, including not less than 30 cases, six months'; (6) Ophthalmic Surgery, three months'. Two examinations have to be passed. The Previous Medical or Half M.B. Examination, including Physics and Chemistry, Botany and Zoology, Anatomy and Institutes of Medicine (Practical Histology and Physiology), may be passed when credit has been obtained *for the corresponding subjects*, and these may be taken separately if desired. The Final Examination is subdivided into five sections, comprising Applied Anatomy (Medical and Surgical), Applied Physiology, Jurisprudence and Hygiene, Materia Medica and Therapeutics, Medicine, Surgery, Pathology, Midwifery, Gynæcology, Obstetrical Anatomy, Clinical Medicine, Mental Diseases, Clinical Surgery, Operations, Clinical Ophthalmology. The first seven of these subjects may be passed in the fourth year and the last eight in the fifth year. Fee for the *Liceat ad Examinandum*, £10. Fee for the degrees, £17.

Doctor in Medicine.—A Doctor in Medicine must be a Bachelor in Medicine of at least three years' standing, or have been qualified to take *the degree of* M.B. *for* three years, and must read a thesis before the Regius Professor of Physic. Total amount of fees for this degree, £13.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years *from the date of his registration* in the study, or study and practice, of his profession. He must then pass an examination in the *following* subjects:—1. Clinical Surgery. 2. Operative Surgery. 3. Surgical Pathology. 4. Surgery 5 Surgical Anatomy (on the dead subject), and one of the following optional subjects:—1. Surgery in one of the following branches—viz., Ophthalmic and Aural, Gynæcological, and Dental. 2. Mental Disease. 3. Medical Jurisprudence and Hygiene. 4 Advanced Anatomy and Physiology. 5 Comparative Anatomy. Fee for the degree of Master in Surgery, £11.

Master in Obstetric Science.—A Master in Obstetric Science must have passed the M.B. and B.Ch. examinations, and produce a certificate of having attended a summer course in Obstetric Medicine and Surgery.[3] He is then *required to pass an examination in the following subjects*:—1. Practice of Midwifery 2 Gynæcology. 3 Anatomy of Female Pelvis and Elementary Embryology. 4. Clinical Gynæcology. *Fee for the degree of Master in Obstetric* Science. £5.

University Diplomas.—Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and five years in Medical Studies. The Course and Examination *necessary for the diplomas* are the same as for the degrees except that the candidate is not required to attend the Lectures on Botany and Zoology, nor to pass the Previous Medical examination in *those subjects*. A diplomate, on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor by attending the Lectures on Botany and Zoology, passing the Previous Medical examination in those subjects, and paying the degree fees. Fee for the *Liceat ad Examinandum*, £10. Fee for the diplomas in Medicine, Surgery, and Midwifery, £11.

ROYAL UNIVERSITY OF IRELAND.

All Degrees, Honours, Exhibitions, *Prizes*, Scholarships, and Studentships in this University are open to students of either sex.

Candidates for any degree in this University must have passed the Matriculation Examination. *Students from* other universities and colleges are included in this rule.

The following degrees, &c., are conferred by the University in this Faculty:—Bachelor of Medicine Doctor of Medicine, Bachelor of Surgery, Master of Surgery, Bachelor of Obstetrics and Master of Obstetrics; in Sanitary Science, a special diploma; and in Mental Disease, a special diploma.

The Medical Examinations, except those for the diploma in Sanitary Science and the First Medical Examination, will be held twice yearly—viz in April and in *October*. The examination *for the diploma* in Sanitary *Science* will be held in July, and the First Medical Examinations in June and September.

The course for degrees in Medicine, &c., is of at least five years' duration.

The First Examination in Medicine.—Students may be admitted to this examination after the lapse of one academical year from the time of their matriculation. They must also have previously passed the First University Examination and completed the first year of the medical curriculum. *The subjects of this examination are* Natural Philosophy Systematic Chemistry, Zoology and Botany. The *examination in each subject will comprise two parts*:—1. A written examination. 2. Practical work and oral examination. For Chemistry the practical examination takes place at the close of the second year. Particular weight will be given to the practical part of the examination. Candidates at the First Examination in Medicine who at the First University Examination did not obtain 30 per cent. of the marks assigned to French or German will be required to present themselves for a qualifying examination in French or German. Failure to obtain 30 per cent. of the marks assigned to either of these languages will involve the loss of the examination.

The Second Examination in Medicine.—Students will be admitted to this examination after the lapse of one medical year from the time of passing the First Examination in Medicine, provided they have completed the second year of the medical curriculum. The subjects for this examination are Anatomy, Physiology, and Practical Chemistry.

The Third Examination in Medicine—Students will be admitted to this examination after the lapse of one medical year from the time of passing the Second Examination in Medicine, provided they have completed the third year of the medical curriculum. The subjects for this examination will be Anatomy, Physiology, and Materia Medica (*Pharmacology and* Therapeutics).

The Examination for the Medical Degrees.—Students will be admitted to this examination after the lapse of not less than one medical year from the time of passing the Third Examination in Medicine, provided they have completed the course of medical studies prescribed for the entire medical curriculum. The examination consists of three parts or divisions:—(*a*) Medicine, including Therapeutics and Pathology, Mental Diseases, Medical Jurisprudence and Hygiene (*b*) Surgery, Theoretical, Clinical, Operative; Surgical Anatomy, with Ophthalmology and Otology; Surgical Pathology. (*c*) Midwifery and Gynæcology, with Diseases of Children. Each part of this examination must be passed as a whole. Upon completing satisfactorily his examination in all three divisions the candidate will, in addition to the parchment diplomas recording his admission to the Medical Degrees of M.B., B.Ch., and B A O, receive a certificate of having passed a qualifying examination in the subjects of Medicine Surgery, and Midwifery. The fee for this certificate is £10, which must be paid prior to the candidate's admission to the Medical Degrees.

M.D Degree.—*Candidates may present themselves for the* examination for this degree after the lapse of three academical years from the time of obtaining the degree of M B They must at the same time produce a certificate of having been, *for* at least two academical years engaged in hospital or private, medical surgical, or obstetrical practice, or in the military or naval medical service. Every candidate will be examined at the bedside, and required to diagnose at least three medical cases, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners and to discuss all the questions arising thereon

The M.Ch Degree—This degree will be conferred only on graduates in Medicine of the University of at least three years' standing. They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval medical service. The examination for this degree will comprise Surgical Diseases and Surgery, both theoretical and operative; Surgical Anatomy; Ophthalmology and Otology; and will include—(*a*) a written examination; (*b*) a clinical examination; (*c*) an examination *on Surgical* Instruments and Appliances; and (*d*) an examination in Operative Surgery.

The Mastership in Obstetrics—This degree will be conferred *only on graduates in Medicine of the University* of at least three years' standing. They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval military service. The examination will comprise the Theory and Practice of Midwifery and of Diseases of Women and Children and the Use of Instruments and Appliances and will include—(*a*) a written examination; (*b*) a clinical examination as far as practicable; (*c*) an oral examination, with practical illustrations; and (*d*) an examination on Instruments and Appliances.

---

[3] Existing graduates in Medicine of the standing of M D are not required to attend this course.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND [4]

Regulations relating to the several Examinations applicable to Candidates who commenced their Professional Education on or after Jan. 1st, 1892.

Any candidate who desires to obtain both the licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to complete five years of professional study at recognised Medical Schools and Hospitals and to comply with the following regulations and to pass the examinations hereinafter set forth. (One of the five years may be spent in an Institution recognised by the Board for instruction in Chemistry, Physics, Practical Chemistry, and Biology.)

Professional Examinations.—There are three Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to Mr. F. G. Hallett, secretary of the Examining Board, Examination Hall, Victoria Embankment, W.C., fourteen clear days before the day on which the examination commences, transmitting at the same time the required certificates.

The subjects of the First Examination are—Chemistry and Physics, Practical Pharmacy, and Elementary Biology. A candidate may take this examination in three parts at different times. A candidate will be admitted to examination in Chemistry and Physics, in Practical Pharmacy, and Elementary Biology, on producing evidence of having passed the required Preliminary Examination and of having received instruction in these subjects at a recognised institution, *or he may take Pharmacy* at any time during the curriculum. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected. If referred in Chemistry or Biology he must produce evidence of further instruction at a recognised institution. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in Medicine on any of the subjects of this examination conducted at a university in the United Kingdom, in India, or in a British colony will be exempt from examination in those subjects in which he has passed.

The fees for admission to the First Examination are as follows: For the whole examination, £10 10*s*; for re-examination after rejection in Part I., £3 3*s*; and for re-examination in each of the other parts, £2 2*s*.

The subjects of the Second Examination are Anatomy and Physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the Second Examination at the expiration of two winter sessions and one summer session (or fifteen months during the ordinary sessions) from the date of passing the Preliminary Examination, and after the lapse of not less than 12 months or one Winter and one Summer Session from the date of passing Parts I. and III. of the First Examination on production of the required certificates of professional study

A candidate referred on the Second Examination will be required, before being admitted to re examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, his Anatomical and Physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the Second Examination are: £10 10*s*. for the whole examination, and £6 6*s*. for re-examination after rejection.

The subjects of the Third or Final Examination are: Part I. Medicine, including Medical Anatomy, Pathology, Practical Pharmacy, Therapeutics, Forensic Medicine, and Public Health. Candidates who have passed in Practical Pharmacy at the First Examination will not be re-examined in that subject at the Third Examination. Part II. Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances. Part III. Midwifery and Diseases Peculiar to Women. Candidates may present themselves for examination in Midwifery and Diseases of Women at any time after the completion of the fourth year of professional study at a Medical School and Hospital, not less than one year after passing the Second Examination, on production of the required certificates. Candidates may take this examination in three parts at different times, or they may present themselves for the whole examination at one time. They will be required to produce the following evidence before being admitted to the several parts of the Third, or Final Examination—viz., in Medicine, of having attended Lectures on Medicine, Pathology including Bacteriology, Pharmacology and Therapeutics, Forensic Medicine, and Public Health; Practical Instruction in Medicine; Medical Hospital Practice during two winter and two summer sessions; Demonstrations in the Post-mortem Room during 12 months; Clinical Lectures on Medicine during nine months; of having discharged the duties of Medical Clinical Clerk; Practice of a Fever Hospital and Clinical Demonstrations at a recognised Lunatic Asylum; in Surgery, of having attended Lectures on Surgery and Pathology including Bacteriology; Practical Instruction in Surgery; of having performed operations upon the Dead Subject; Surgical Hospital Practice during two winter and two summer sessions; Demonstrations in the Post-mortem Room during 12 months; Clinical Lectures on Surgery during nine months; of having discharged the duties of Surgical Dresser, and Clinical Instruction in Ophthalmology; in Midwifery of having attended Lectures on Midwifery; Practical Instruction in Midwifery; Clinical or other Lectures, with Practical Instruction in Diseases Peculiar to Women; and of attendance on 20 Labours.

Fees for admission to the Third or Final Examination are as follows: For the whole examination, £21. Part I. For re-examination in Medicine, including Medical Anatomy, Pathology, Therapeutics, Forensic Medicine, and Public Health, £5 5*s*.; for re-examination in Practical Pharmacy (if taken at this examination), £2 2*s*. Part II. For re-examination in Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances, £5 5*s* Part III. For re-examination in Midwifery and Diseases Peculiar to Women, £3 3*s*.

A candidate referred on the Third or Final Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection and will be required, before being admitted to re-examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the Medical and Surgical Practice, or the Medical or Surgical Practice, as the case may be, during the period of his reference; and in regard to Midwifery and Diseases Peculiar to Women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

ROYAL COLLEGES OF SURGEONS AND PHYSICIANS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or in Glasgow, or in Edinburgh and Glasgow, the student may obtain the diplomas of the three Bodies.

The three Bodies grant their Single Licences only to candidates who already possess another and opposite qualification in Medicine or Surgery, as the case may be, recognised by them. Copies of the Regulations for the Single Licence of any of the Bodies may be had on application to the respective secretaries.

Professional Education.—1. Candidates who commence medical study *before* Jan 1st, 1892 must have been engaged in professional study during 45 months from the date of registration as medical students by the General Medical Council, which period shall include not less than four winter sessions' attendance at a recognised medical school. 2 The candidate must produce certificates or other satisfactory evidence of having attended the following separate and *distinct courses of instruction*: Anatomy during at least six months; Practical Anatomy, twelve months; Chemistry, six months, Practical or Analytical Chemistry, three months; Materia Medica, three months; Physiology, six months; Practice of Medicine, six months; Clinical Medicine, nine months; Principles and Practice of Surgery, six months; Clinical Surgery, nine months; Midwifery and the Diseases of Women and Children, three *months*; Medical Jurisprudence, *three months*; Pathological Anatomy, three months. The six months' courses delivered in Scotland must consist of not fewer than 100 lectures. The three months' courses must consist of not fewer than 50 lectures The number of lectures certified as attended at any school not situated in Scotland should not be less than three fourths of the total number of lectures delivered in a course. 3 The candidate must also produce the following certificates.—(*a*) Of having attended not less than six cases of labour, three of these to be conducted personally under the direct superintendence *of the practitioner who signs the certificate, who must be* a registered medical practitioner. (*b*) Of having attended, for three months, instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy (*c*) Of having attended for 24 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for *clinical instruction and possessing distinct staffs of* physicians and of surgeons (*d*) Of having attended for six months (or three months with three months' hospital clerkship) the practice of a public dispensary specially recognised by any of the above authorities, or the out-patient practice of a recognised general hospital, or of having acted for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the coöperating authorities; this attendance should be made after the student has passed the First and Second Examinations (*e*) *Of having been instructed* by a registered medical practitioner in the Theory and Practice of Vaccination, and of having performed operations under the teacher's inspection, during a period of not less than six weeks

---

[4] The diploma of Member of the Royal College of Surgeons of England and the Licence of the Royal College of Physicians of London are no longer granted separately except to students who commenced their professional study prior to Oct. 1st, 1884.

Candidates shall be subjected to three Professional Examinations and they may enter either for the whole of an Examination or for a division thereof.

First Examination.—The First Examination shall embrace the two divisions of (1) Chemistry and (2) Elementary Anatomy and Histology, and shall take place not sooner than the end of the first year, including the period of a winter and a summer session For the whole Examination taken at one time the sum of £5 5*s* must be paid to the inspector of certificates not later than one week preceding it, after which no candidate will be entered After rejection for re entry in all subjects, £3 3*s*; for re-entry after obtaining exemption from re examination in one or two subjects, £2 2*s*; for entering for one division of subjects separately, £3 3*s*; and for each re-entry after rejection, £2 2*s* Any candidate who shall produce satisfactory evidence of having passed an equivalent examination in any of the subjects of the First Examination before any of the *boards specified in* the Regulations will be exempt from examination in such subjects

Second Examination.—The Second Examination shall embrace the three subjects of (1) Anatomy, (2) Physiology, (3) [illegible] [illegible] summer session of the second year of study including two winters and two summers The fees for admission to this examination, payable not later than one [illegible] re examination in one or two subjects, £2 2*s*; for entering for one subject separately, £2 2*s*; and for each re entry therein after rejection, £2 2*s* Any candidate who shall produce satisfactory evidence of having passed an equivalent examination in any of the subjects of the Second Examination before any of the boards specified in the Regulations will be exempt from examination in such subject or subjects

Final Examination.—The Final Examination shall embrace the three divisions of—(1) the Principles and Practice [illegible] Anatomy, and [illegible] Principles and [illegible] and Surgical [illegible] y and Gynæ- [illegible] (which divisions may be entered for separately at different times); and shall *not take place before* the *termination* of the full period of study. The fees for this Examination, payable not later than one week before the examination day, are as follows. For the whole Examination, taken at one time, in the case of candidates who have passed the First and Second Examinations, £15 15*s* of which £10 10*s* shall be returned to unsuccessful candidates. For entering for each of the three divisions of subjects separately, £6 6*s*, and on re-entry after rejection, £2 2*s* in respect of each division or part thereof This rule will also apply to any subsequent rejection. Any candidate admitted to the Final Examination, on *the footing of having passed* in the subjects of the First and Second Examinations at a recognised board, shall, on entering, pay the full fee of £26 5*s*,

All candidates shall be subjected, in addition to the Written and Oral Examinations, to Clinical Examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical Use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface Markings, &c.

REGULATIONS FOR CANDIDATES WHO COMMENCED STUDY *after* JANUARY 1ST, 1892

In addition to the courses above prescribed candidates are required to attend the following courses Physics three months; Elementary Biology three months; Diseases and Injuries of the Eye, three months, Insanity, three months; Infectious Diseases, three months, and a third year of Hospital Practice with Clinical Instruction (which may include the study of special diseases)

The curriculum lasts for five years; the fifth year should be devoted to clinical work at one or more public hospitals or dispensaries Six months of the fifth year may be passed by the student as a pupil to a registered practitioner possessing such opportunities of imparting [illegible] be deemed satisfactory by the [illegible] The student's regularity of atten[illegible] patient departments of the hospitals and at the post-mortem examinations should be duly ascertained and noted on the certificate

Candidates shall be subjected to four Professional Examinations.

First Examination.—The First Examination shall embrace the following divisions of subjects—(1) Physics, (2) Chemistry, and (3) *Elementary Biology*. The fees payable for admission to the First Examination, shall be for the whole Examination. £5; for each division separately, £2 10*s*.

Second Examination.—The Second Examination shall embrace Anatomy and Physiology including Histology; and candidates may be admitted to this Examination at the end of the second year of medical study The fees payable for admission to the Second Examination shall be—for the whole Examination £5

Third Examination.—The Third Examination shall embrace Pathology and Materia Medica with Pharmacy. The *fees payable for admission to the Third Examination* shall be—for the whole Examination, £5; for re entry in both subjects after rejection, £3

Final Examination.—The Final Examination shall not be passed earlier than the end of the fifth year of study and shall embrace the following subjects.—Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; Surgery, including Surgical Anatomy Clinical Surgery, and Diseases and Injuries of the Eye; Midwifery and Diseases of Women and of New born Children; and Medical Jurisprudence and Public Health All candidates shall be subjected, in addition to the Written *and Oral* Examinations, to Clinical Examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface markings, &c. The fees payable for the Final Examination shall be,—for the whole Examination, £15, for re-entry in all subjects after rejection, £5.

There are six periods of Examination annually, four in Edinburgh and two in Glasgow, and candidates may present themselves at either examining centre irrespective of the place of the previous examination. The Registrar in Edinburgh is Mr. J. Robertson, Solicitor, 54, George-square; and the Registrar in Glasgow, Mr. A. Duncan, LL.D., 242, St. Vincent-street, to whom fees and certificates must be sent.

Note.—In applying for copies of the Regulations students should state whether they commenced medical study before or after Jan. 1st, 1892.

SOCIETY OF APOTHECARIES OF LONDON.

There are two examinations—Primary and Final. The Final Examination is divided into Section I. and Section II. The Primary Examination is held quarterly, on the first Wednesday and on the Monday and Thursday of the same week, in the months of January, April, July, and October. Final Examinations are held monthly.

The Primary Examination consists of two parts. Part I. Elementary Biology; Chemistry, Chemical Physics, including the Elementary Mechanics of Solids and Fluids, Heat, Light, and Electricity; Practical Chemistry; and Materia Medica and Pharmacy. A synopsis indicating the range of the subjects in the examination will be sent with the regulations on application. Evidence of instruction in these subjects must be produced prior to examination. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months' Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the event of the candidate having previously passed in one. Evidence must be produced of the candidate's course of study. A schedule for the Primary Examination, to be obtained of the Secretary, must be signed by the Dean of the Medical School or other authority. Section I. of the Final Examination consists of three parts. Part I. includes the Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulation, Instruments, and Appliances. Part II. includes the Principles and Practice of Medicine, Pharmacology, Pathology and Morbid Histology; Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases. Part III. includes Midwifery, Gynæcology, and Diseases of New-born Children and the Use of Obstetric Instruments and Appliances. Section I. of the Final Examination cannot be passed before the expiration of 45 months after registration as medical student, during which time not less than three winter sessions and two summer sessions must have been passed at one or more of the medical schools connected with a general hospital recognised by the Society. Section II. of the Final Examination consists of two Parts. Part I. Clinical Surgery; Part II. Clinical Medicine and Medical Anatomy. Section II. cannot be passed before the end of the fifth year.

The course of study for the Primary Examination is as follows:—Elementary Biology, not less than three months; Chemistry and Chemical Physics, six months; Practical Chemistry, three months; Pharmacy and Dispensing, three months; Anatomy, six months; Practical Anatomy with Demonstrations, twelve months; Physiology, six months; Histology with Demonstrations, three months. The study of these subjects must be pursued at a Medical School recognised by the Society. Evidence of having received instruction in the subjects of Part I. of the Primary Examination before registration as medical student will be accepted. Instruction in Pharmacy and Dispensing must be given by a registered medical practitioner or by a member of the Pharmaceutical Society by examination or in a public hospital, infirmary, or dispensary.

The course of study for the Final, Section I., Examination includes attendance on the Surgical and Medical Practice (with Post-mortem Examinations) at a hospital connected with a medical school for a period of one winter and one summer session; lectures on the Principles and Practice of Surgery, six months; Practical Surgery, three months; Clinical Surgical Lectures, nine months; Dressership, six months; Performance of Surgical Operations on the Dead Body; lectures on Principles and Practice of Medicine, six months; Pathology, three months; Clinical Medical Lectures, nine months; Clinical Clerkship,[5] six months; Forensic Medicine, Hygiene, and Insanity, three months; Midwifery and Gynæcology, three months; Clinical Instruction in the same, three months; a course of Practical Midwifery; attendance on 20 Midwifery cases. The course of medical study must extend over the above-mentioned period of 45 months.

The course of study for the Final Examination Section II. includes either attendance on the Practice of Medicine and Surgery at a hospital or other institution recognised by the Society for a further period of 12 months, or six months as above and six months as a pupil of a registered practitioner holding a public medical or surgical appointment, or attendance at two special hospitals for six months (three months at each hospital), and for six months at a general hospital, all such hospitals to be recognised by the Society. Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, Laryngology with Rhinology and Otology, Dermatology, and Diseases of Children. No candidate is eligible for the Final Examination who has not completed the curriculum prescribed by the Society, in evidence of which a schedule, to be obtained of the Secretary, must be produced, signed by the Dean of the Medical School or other authority. Prior to Section II. of the Final Examination the candidate must produce certificates: (1) of being 21 years of age; (2) of moral character; (3) of the course of medical study; and (4) of proficiency in vaccination signed by a teacher authorised by the Local Government Board. Candidates intending to present themselves for examination are required to give 14 days' notice. A form for this purpose will be sent on application.

The fee for the Licence is 15 guineas. On and after Jan. 1st, 1902, the fee for the Licence will be 20 guineas. The examination offices are open from 10 A.M. to 4 P.M.; on Saturdays from 10 A.M. to 1 P.M. All letters should be addressed to the Secretary, Court of Examiners, Society of Apothecaries of London, Blackfriars, E.C.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who can present certificates of having fully completed the course of study as laid down in the curriculum. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, also with the privileges of the Apothecary Licence. There are four professional examinations, the total fees in connexion with which amount to 21 guineas. Ladies are eligible for the diploma. Candidates already on the Register will receive the diploma of the Hall upon passing an examination in the subjects which are not covered by their previous qualifications and on paying a fee of 10 guineas. If medicine or surgery be required two guineas extra will be charged.

The fees payable for each examination are as follows:—first professional, £5 5*s.*; second, £5 5*s.*; third, £5 5*s.*; final examination, £6 6*s.* If a candidate gives three clear days' notice of inability to attend he may present himself at the ensuing examination without any further fee. A candidate is allowed for each professional examination which he has completed at any other licensing body except the final. If he has passed only in some of the subjects in a given examination he has to pay the whole of the fee for that examination. The fees for re-examination are for each subject £1 1*s.*, excepting in the subjects of chemistry, pharmacy, surgery, medicine, second anatomy, and ophthalmology, the fees for which are two guineas each. The fee for the final alone is £15 15*s.* when the other examinations have been taken elsewhere. All examination fees are to be lodged in the Sackville-street Branch of the Royal Bank of Ireland to the credit of the Examination Committee. Applications and schedules, together with bank receipt for the fee, must be lodged with the Registrar, Apothecaries' Hall, 40, Mary-street, Dublin, 14 clear days before the *first* day of examination.

---

[5] These offices must be held at a hospital, or other institution recognised by the society.

There are four examinations—first, second, third, and final. The first three are held quarterly on the third Monday in January, April, July, and October; there are only two finals, in January and July. The first examination includes biology, physics, theoretical and practical chemistry, with an examination at the bench. Pharmacy is put down in this examination, but it may be taken at any of the first three examinations. Candidates holding a Pharmaceutical licence are exempt from this subject. Osteology (first anatomy) is also a subject of the first professional examination. The subjects for the second professional are anatomy of the whole body (the examination in this subject is practical), materia medica and therapeutics, physiology and practical histology. The third examination consists of pathology, materia medica if not taken at second examination, medical jurisprudence, and hygiene. The final examination includes medicine, oral and clinical surgery, including operations, clinical and oral, clinical ophthalmic surgery, midwifery, and gynæcology. Written papers are required on all these subjects.

Candidates who desire to obtain the Letters Testimonial of the Apothecaries' Hall in Ireland must before proceeding to the final examination produce evidence of having been registered as a medical student for 57 months, also of having attended courses of instruction as follows:—one course each (winter course of six months) of the following: anatomy (lecture), chemistry (theoretical), midwifery, practice of medicine, physiology or institutes of medicine, surgery, dissections, two courses of six months each. Courses of three months: materia medica, medical jurisprudence, chemistry (practical), practical physiology and histology, operative surgery, physics, clinical ophthalmology, biology, clinical instruction in mental disease, pathology, and vaccination. Medico-chirurgical hospital, 27 months to be distributed, at the student's own discretion, over the last four years of his study. The candidate may substitute for nine months in this hospital attendance six months as a resident pupil. He will be required to present a certificate of having taken notes of at least six medical and surgical cases recorded under the supervision respectively of a physician and surgeon of his hospital. Three months' study of fever—which may be included in his 27 months' hospital attendance—in a hospital containing fever wards, and having taken notes of five cases of fever—viz., either typhus fever, typhoid fever, scarlet fever, small-pox, or measles. Six months' practical midwifery and diseases of women during the winter or summer of the third or the fourth year at a recognised lying-in hospital or maternity. Three months' practical pharmacy in a recognised clinical hospital or a recognised school of pharmacy, or a year in the compounding department of a licentiate apothecary or a pharmaceutical chemist. Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years. Each candidate must produce evidence of having before entering on medical studies passed a preliminary examination in general education recognised by the General Medical Council and of having been registered by that Council as a student in medicine. Certificates of medical study will not be recognised if the commencement of the course to which the certificate refers dates more than 15 days prior to such registration, except in the subjects of physics or biology. This registration is not undertaken by the Hall, but the student must apply to the Registrar of the General Medical Council that he may be so entered. The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar at 40, Mary-street, Dublin.

UNIVERSITY OF BRUSSELS.

British and other practitioners holding registrable qualifications are admitted to the examination for the Doctorate of the University of Brussels without further curriculum. It is essentially a *practitioner's* examination and is separate from that intended for the Belgian students who take up the medical curriculum of the University. The fees are—For matriculation, £8 12*s.*; for 1st Part, £4 8*s.*; for 2nd Part, £4 4*s.*; for 3rd Part, £4 8*s.*; for legalisation of diploma, 8*s.*—total, £22. Candidates who have paid in advance the fees for the three examinations, and are unsuccessful in the first, recover the fees paid for the second and third; those who fail in the second recover the fees paid for the third examination. Unsuccessful candidates are allowed to come up again three months after rejection on payment of examination fees only, provided this second appearance be in the course of the same academical year (October 1st to June 30th) otherwise they must renew the payment of the matriculation fee of £8 12*s.* There are three examinations, viz.—1st Part: General Medicine; Pathology and Morbid Anatomy; General Therapeutics; Materia Medica and Pharmacology; Special Therapeutics and Mental Diseases. 2nd Part: Surgery; Midwifery; Hygiene; and Medical Jurisprudence. 3rd Part: Clinical Examination in Medicine at the Hospital; Clinical Surgical Examination; Examination in Midwifery, consisting of obstetrical operations on the mannequin (doll and model of pelvis); Examination in Operative Surgery, consisting of some of the usual operations on the dead subject, such as Amputation, Ligature of an Artery, &c.; Regional Anatomy on the Dead Body, with Dissections; and Ophthalmology. The first and second parts are theoretical and the third is mainly practical and clinical. The time required for the three examinations seldom exceeds ten days, and is usually less. Candidates have the option of passing each part separately or of taking the three together, and the latter is the usual course; also of demanding a written examination on payment of an additional fee of one guinea for each part, a rule of which candidates rarely or never avail themselves. The examinations, which are *vivâ voce*, take place on the first Tuesday in November, December, February, May, and June. Candidates should appear with their diplomas at the Secretary's office not later than 2 P.M. on the day preceding the examination. Most of the examiners speak English and those who do not examine through the medium of an interpreter. Great importance is attached to practical knowledge, but candidates must also possess sound theoretical knowledge, the standard required varying with the subject. Pathological and other specimens are not usually shown. There are in England at present over 600 graduates holding this degree, and an English Association of Brussels Medical Graduates has been in existence many years.

Further information may be obtained from Dr. Walter Reeve, 2, Harewood-place, Hanover-square, W.

THE ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

Consequent upon the issue of the Royal Warrant published in Army Orders dated July 1st, 1898, the Army Medical Staff and the Medical Staff Corps were formed into the Royal Army Medical Corps. Medical officers also have been placed, as regards sick leave of absence on full pay, on the same footing as that laid down for regimental officers. By a Royal Warrant, dated Nov. 10th, 1891, Art. 1208*b* of the Pay Warrant was revised by inserting the words "an officer of our Royal Army Medical Corps" after the words "combatant officer," thus giving medical officers an equal title with combatant officers to reckon time on half-pay towards retirement, when the half-pay has been due to ill-health contracted in the performance of military duty. Under the Royal Warrant of July, 1895, time on half-pay not exceeding a year may under similar circumstances also reckon towards promotion. In the New Royal Warrant it was announced that the Queen had been pleased to approve of the following ranks for the officers of the Royal Army Medical Corps:—Colonel, Lieutenant-Colonel, Major, Captain, and Lieutenant. The Warrant also states that the Medical Staff of the Army shall in future consist of Surgeon-Generals (ranking as Major Generals). Officers of the Royal Army Medical Corps holding appointments in the Household Troops are to be borne as seconded officers on the establishment of the Royal Army Medical Corps. The substantive rank of the Director-General of the Army Medical Service is that of Surgeon General.

Admission into the Royal Army Medical Corps and Indian Medical Services is gained as the result of competitive examination. Under special conditions the admission to the former may take place by nomination under the authority of the Secretary of State for War. The number of nominated candidates for the Royal Army Medical Corps is not to exceed the number of candidates advertised for to compete at the examination for admission to the Army Medical School as surgeons-on probation for the Royal Army Medical Corps. During several sessions of the school the number of nominated candidates has exceeded the number of surgeons-on-probation who have been admitted by examination. The latter, if found qualified at the Netley examination, rank senior to the nominated officers in the army—a just advantage. The candidates are nominated by the Secretary of State for War, who invites such governing bodies of public schools of medicine in the United Kingdom or Colonies as he may think proper to propose probationers. The Secretary of State for War will from time to time fix the order of precedence and the proportion in which the several schools of medicine shall be offered the nomination of candidates. Candidates for both services must, before being admitted to examination, possess a double qualification to practise Medicine and Surgery and be registered under the Medical Act. They are also now required to produce certificates of having acted as a medical clinical clerk for six months, as surgical dresser for another six months, and of having had not less than three months' instruction at an ophthalmic hospital or the ophthalmic department of a general hospital, including a course on errors of refraction. They must also furnish satisfactory certificates of moral character. A candidate for the Royal Army Medical Corps must be between 21 and 28 years of age, in good mental and bodily health, and must sign a declaration upon honour that he is of pure European descent; he must also state whether he holds, or has held, any commission or appointment in the public services; for the Indian Service a candidate must be between 21 and 28 years of age, of sound bodily health, and a natural-born subject of His Majesty. Both are examined as to physical fitness by a Board of Medical Officers The standard of fitness is set forth in Appendix I. of the regulations for admission to the Royal Army Medical Corps. These conditions being satisfied, the candidate is admitted to the competitive examination, which is usually held in London twice a year, in the months of February and August An entrance fee of £1 is required from each candidate admitted to the competition, and is payable at the conclusion of the candidate's physical examination, if he be pronounced fit. No candidate for the Indian Service will be allowed to compete on more than three occasions (At the last competition, for the first time in the annals of the Indian Medical Service, the number of candidates only equalled the number of vacancies advertised) The subjects of examination are divided into *compulsory* and *voluntary*. The former comprise Surgery (1200 marks), Medicine, including Therapeutics and the Diseases of Women and Children (1200 marks), Anatomy and Physiology (600 marks), Chemistry and Pharmacy, and a practical knowledge of Drugs (600 marks). The examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside The eligibility of the candidate for admission into the service is determined by the result of this part of the examination. By an Army Order dated May 1st, 1895, no candidate shall be considered eligible who shall not have obtained at least one-third of the marks obtainable in each of the compulsory subjects, and at least one-half of the aggregate of marks for all the compulsory subjects. The *voluntary* subjects are French (200 marks), German (200 marks) Hindustani (200 marks), and Natural Sciences: (*a*) Physics (300 marks); (*b*) Zoology (300 marks); (*c*) Geology and Physical Geography (300 marks); and (*d*) Botany (300 marks). A candidate may not present himself for examination in more than two of the subjects included under the term 'Natural Sciences." A number less than one-third of the marks obtainable in each of the voluntary subjects will not be allowed to count in favour of a candidate who has qualified in the compulsory subjects. Although the results of the examination in voluntary subjects do not affect the question of the eligibility of the candidate for a commission, they influence his position on the list, which is determined by the numbers obtained under the two heads conjointly. A candidate for the Royal Army Medical Corps when submitting his application may also enter for the Indian Medical Service (and *vice versâ*), subject to his satisfying the Secretary of State for India or War that he is eligible under the regulations for that service. The names of the successful candidates for the two services will be placed on one list in order of merit, as determined by the total number of marks each has obtained in both the compulsory and voluntary subjects So far as the number of vacancies will permit, the successful candidates will be allotted, according to their position on the list, to the service for which they have expressed a preference, subject to their having been accepted prior to examination as eligible for that service. After having passed this examination the successful candidates for both services are sent to the Army Medical School at Netley as "surgeons-on-probation," receiving a daily pay of 8*s* and certain allowances, to go through a four months' course of instruction in the special duties required of them in the services; or, in the case of the Royal Army Medical Corps, such a course at the Army Medical School as the Secretary of State shall decide on as sufficient. They are required to attend the Royal Army Medical Corps mess at Netley and to conform to the rules and regulations thereof. The staff of the school consists of four professors, all of them men of high standing in their special departments. The Professorship of Military Medicine is held by Colonel K. Macleod, M.D., I.M S. Colonel W. F. Stevenson, M.B. is Professor of Military Surgery, Major H. R Firth, F.R C S. Eng. of Military Hygiene; and Dr. A. E. Wright, of Pathology. There is an Assistant Professor for each of these subjects who is an officer of the Royal Army Medical Corps. The lectures on Military Surgery include gunshot and other wounds, transport of sick and wounded, duties of army medical officers in the field, on board troopships and transports, recruiting, and other duties incident to military service. Those on Military Medicine treat of tropical and other diseases to which soldiers are exposed in the course of their service, the mortality and invaliding by disease, in peace and war, at home and abroad, the management of lunatics under the conditions of military service, &c. The course of six lectures on Lunacy and Military Asylum work is delivered at the Netley Lunatic Asylum by Lieutenant-Colonel Chester, M B. The course of Hygiene comprises the examinations of water and air, the general principles of diet, with the quality and adulterations of food and beverages, the sanitary requirements of barracks, hospitals, and camps, the consideration of the clothing, duties, and exercises of the soldier, and the circumstances affecting his health, with the best means of preventing disease, and instruction in the mode of preparing the various statistical and other returns required of the medical officer. The Pathological course includes bacteriology and demonstrations in physiological chemistry. The surgeons-on-probation are detailed for duty in the wards of the hospital, under the Professors and Assistant Professors of Medicine and Surgery. They, as a rule, spend two months in the medical and two months in the surgical division of the hospital, and there they are taught practically the details of the management of patients in a military hospital, the registration of their diseases, the duties of invaliding, the modes of filling up the regulation statistical returns and other service documents. The surgeons-on-probation are provided with quarters and are extra members of the mess at Netley. They are required to provide themselves with the regulation undress and mess uniform of a lieutenant, but without the sword, sword-belt, dress trousers, forage cap, patrol jacket, and badge of rank. After having passed through the course of instruction they are required to pass a qualifying examination in the subjects taught in the school, and their position on the list of those recommended for commissions is determined by the combined results of the competitive and final examinations. At the close of each session nine prizes are awarded: the Herbert Prize of £20 to the surgeon-on-probation who has obtained the highest number of marks at the Netley examination; the Parkes Memorial Bronze Medal to the one who gains the highest number of marks in the examination in Hygiene; the de Chaumont prize of books to the one who takes second place in Hygiene; the Martin Memorial Gold Medal for the highest number of marks in the examination on Military Medicine; the Montefiore Medal and £21, awarded for Military Surgery; the Montefiore Second Prize, a revolver to the surgeon-on-probation who obtains the second highest number of marks in this branch; the Maclean prize of books for Clinical Medicine and Surgery and for Ward Work; a prize of books for the highest number of marks gained in Pathology; and the Marshall Webb prize of £5 and a bronze medal for Hospital Administration

At the close of the Netley Session those surgeons-on-probation who have obtained one third of the possible total of marks in each subject and have satisfied the authorities that they possess the [illegible] and character for permanent [illegible] for commissions as Lieutenant [illegible] of the Royal Army Medical Corps who pass out of the Army

Medical School at one qualifying examination will take precedence among each other as lieutenants, as follows —(*a*) Those appointed by competition according to the order of merit as determined by the combined results of the competitive and qualifying examinations, with priority over any joining under paragraph (*b*) (*b*) Those appointed on nomination, according to the number of marks they individually obtain at the final examination at the Army Medical School, but junior to all those appointed by competition [illegible] e of the day of passing out of [illegible] he Lieutenants of the British [illegible] n Netley to Aldershot, where [illegible] course of instruction in company and ambulance drill and equitation The officers of the Indian Medical Service do not go to Aldershot but undergo, whilst at Netley a course of instruction in company and ambulance drill and in other military duties The position of the officers of the Indian Service on the list of Lieutenants is determined by the combined results of the London and Netley examinations, and, as far as the requirements of the service permit, they have the choice of commands in India—i e, Bengal, Punjab Madras, or Bombay—according to their position in that list All officers appointed to the Indian Medical Service are now placed on one list. Though ordinarily employed within the limits of the command to which they are posted, they are liable for employment in any part of India In the *Gazette* dated India Office, August 26th, 1898 it was announced that Her Majesty had deemed it expedient to alter the ranks of the officers of the Indian Medical Service The same military titles as those conferred on the officers of the Royal Army Medical Corps were announced for the officers of the Indian Medical Service

The Royal Army Medical Corps —Every promotion of a medical officer shall be given upon the recommendation of the Commander-in-Chief, with the approval of the Secretary of State Lieutenants, if duly recommended, are promoted to be Captains on completing three years' full-pay service

Captains, if recommended by the Director General, are promoted to be Majors on completing twelve years' full-pay service, of which three must have been passed abroad Before being promoted they will be required to pass an examination, which is intended to test the progress and proficiency of a captain in all those branches of knowledge which are essential to his continued efficiency as a medical officer This examination may be taken at any time after their seventh year of service It will embrace the following subjects (*a*) Surgery and Surgical Anatomy; (*b*) Medicine and Pathology, and (*c*) the theory and practice of Hygiene, especially in relation to military requirements, also the regulations regarding the sanitation of garrisons, quarters, hospitals, &c, as well as of camps and hospitals in the field, and of transports, troop and hospital ships; (*d*) duties of medical officers at home and abroad and at sea, as defined in the regulations, also hospital organisation [illegible] in peace and war, includ [illegible] wounded by land and sea, ([illegible] economy, command, and [illegible] Medical Corps, together with [illegible] of the principles of military law and their practical application (a certificate of proficiency in military law obtained at a garrison class will exempt the holder from examination in the latter)

A certificate will be required from a recognised teacher of surgery in any medical school, at home or abroad, in which operative surgery is taught, showing that the officer has gone satisfactorily through a complete course of operative surgery during the period within which the examination must be taken, and that he is a competent operator

A report on any subject of a practical professional character, to be selected by the officer himself, and certified to be his own composition and in his own handwriting, will also be required Considerable importance will be attached to the literary and scientific merits of this report, which must be furnished before the officer completes twelve years' service

The examinations will be conducted by printed questions which will enter so far into the subject matter of each head selected for examination as to show that the officer's knowledge has been fully tested.

The questions and answers will be forwarded, under a sealed confidential cover, to the Director-General for transmission to the examiners, who will report to the Director General as to the competence of the officer examined.

The examination in Medicine and Surgery will be held by two gentlemen appointed by the Secretary of State; that in Hygiene by the Professor of Hygiene, Army Medical School, Netley; and that in Regulations, Duties, Military Law &c., by an administrative medical officer, nominated for the purpose by the Director General.

Any higher qualification, such as M D, F.R C S, &c, or any diploma in Hygiene and State Medicine, taken after May 1st, 1890, will not exempt Captains from this examination

A Lieutenant in the Royal Army Medical Corps promoted to the rank of Captain on account of distinguished service in the field, shall be eligible for further promotion to the rank of Major, and subsequently to that of Lieutenant-Colonel, when the officer next below him in the rank of Captain or Major respectively becomes eligible by service for promotion to the next higher rank. A Captain so promoted to the rank of Major shall, on the same conditions, be eligible for promotion to the rank of Lieutenant Colonel An officer promoted under this article shall not receive any increase of pay in the rank to which he has been so promoted until he becomes entitled thereto by service

Majors are promoted to be Lieutenant Colonels on completing twenty years' full pay service

A Lieutenant Colonel may be specially selected for increased pay (£1 10s a day) from Lieutenant Colonels who have served at least eight years abroad

The selection of Lieutenant Colonels for advancement to the grade of Colonel is made on the grounds of ability and merit (on the recommendation of the Commander in Chief) In determining which the following points will be considered —The officer to be so selected must have been favourably reported on by the several military officers under whom he may have served, as set forth in their Annual Confidential reports He must be physically fit for general service

A Lieutenant-Colonel, to be eligible for selection as Colonel, must have served abroad at least ten years, of which three must have been in India All promotions from the rank of Lieutenant-Colonel to that of Colonel and from the rank of Colonel to that of [illegible] given for ability and merit, [illegible] Commander in Chief, with the [illegible] State and the grounds of such selection shall be stated in writing In all such cases the amount of service abroad shall be expressly stated All officers under the rank of Colonel are placed on the retired list at the age of fifty five, and those of that rank and of the rank of Surgeon General at the age of sixty, except that in any particular case in which it may be considered necessary for the interest of the public service the age of retirement of a Surgeon General may be extended for a period not exceeding two years From recent promotions which have been made it is evident that Colonels who have passed the age of fifty seven before being selected for the rank of Surgeon General will be passed over in favour of younger officers who can, by reason of age serve a full three years in the rank of Surgeon General The Director General will, unless [illegible] extended, retire on completion [illegible] service in the field a medical [illegible] with the concurrence of the Lords Commissioners of the Treasury, be promoted from any departmental or other rank to that next above it and shall, if promoted to another rank having a fixed establishment, remain supernumerary in that rank until the occurrence of the vacancy to which, in the ordinary course, he would have been promoted The recommendation detailing the services for which the officer may be proposed for promotion shall in such cases be published in the *London Gazette* An officer so promoted shall not receive any increase of pay in the rank to which he has been promoted until he becomes entitled thereto by service In a case of distinguished service in the field for which an officer may merit special reward although there may not be sufficient grounds for his promotion, the Secretary of State shall have the power, with the concurrence of the Lords Commissioners of the Treasury, to grant him a higher rate of pay in his rank, but without alteration of his seniority

Foreign Service —Army Order 85 of June, 1897, states that the periods of service abroad, reckoning from the date of embarkation at home, will (except in the case of a Surgeon-General or Colonel) be five years for all stations abroad (except that on the west coast of Africa), unless such period should be incompatible with the interests of the public service.

Sick Leave.—An officer of the Royal Army Medical Corps may be allowed full pay during sick leave of absence on the same conditions as those laid down for regimental officers.

Service on the West Coast of Africa.—Officers who entered the Royal Army Medical Corps, or volunteered expressly for service on the West Coast of Africa on or after March 1st, 1873, receive double pay while actually serving on the coast. Candidates who present themselves expressly for service in the Royal Army Medical Corps on the West Coast enter under the same qualifications as other candidates, except that they may be admitted up to thirty years of age. After 3 years' actual service on the coast they are eligible for general service. If, however, it be certified by a medical board that any such officer is unfit for further duty on the coast he shall be eligible for general service, though he may not have completed 3 years' service there. For each year's service on the coast an officer is entitled to a year's leave at home on full pay. Each year or portion of a year served on the West Coast reckons double towards voluntary retirement or retired pay, provided that an officer has served 12 months on the coast. An officer volunteering for, or ordered to, the West Coast of Africa receives double pay while actually serving on the coast.

Exchanges.—An officer of the Royal Army Medical Corps shall be permitted to exchange with another officer of such corps, or with a medical officer of the Household Troops, under such conditions and regulations as shall from time to time be made. Exchanges between officers of the Royal Army Medical Corps under the rank of major and medical officers of the Indian Military Forces, and transfers of such officers from either of the above services to the other, shall only be permitted subject to the approval of the Secretary of State for India in Council and on the following conditions:—(1) that the officers have less than seven years' service; (2) that the senior officer exchanging takes the place of the junior on the list and shall not be promoted under Article 359 until the officer next above him has been so promoted; (3) that the junior officer exchanging is placed for seniority next below all medical officers whose commissions have the same date as his own; (4) that the officer transferred is placed for seniority below all medical officers holding the same rank at the time of his transfer, and shall not be promoted under Article 359 until the officer next above him has been promoted; and (5) an officer of the Royal Army Medical Corps who has exchanged or been transferred from the Indian Medical Service shall reckon his previous service towards promotion.

Indian Medical Service.—Officers on appointment are, when possible, provided with passage to India by troopship; when troopship accommodation is not available passage at the public expense is provided by steamer, or a passage allowance granted if preferred. A charge for messing during the voyage is made at the rate of 2s a day. This payment does not include the cost of liquors, which are charged for as extras. Any officer who may neglect or refuse to proceed to India under the orders of the Secretary of State for India within two months from the date of leaving Netley will be considered as having forfeited his appointment, unless special circumstances shall justify a departure from this regulation. A Lieutenant's commission is dated from the day he passes out of the Army Medical School. Lieutenants are promoted to the rank of Captain on completing three years' full-pay service, Captains to the rank of Major after twelve years' full-pay service, and Majors to the rank of Lieutenant-Colonel after twenty years' full-pay service (see Note *, p 659). No examination to qualify for promotion is required. All promotions to higher grades are to be given by selection for ability and merit. In case of distinguished service in the field a medical officer may be at once promoted from any rank to the one next above it, remaining supernumerary in the higher rank until he would have been promoted in ordinary course or until selected for further promotion for which he is eligible. The ages for compulsory retirement are the same as those for the Royal Army Medical Corps. Officers of the Indian Medical Service below the rank of Colonel may be granted: 1. Privilege leave under such regulations as may from time to time be in force. 2. Leave out of India for no longer period than one year, capable of extension to two years' absence from duty, on the following pay:—After arrival in India, on first appointment, £200 a year; after the commencement of the fifth year's service for pension, £250 a year; after the commencement of the tenth year's service for pension, £300 a year; after the commencement of the fifteenth year's service for pension, £400 a year; after the commencement of the twentieth year's service for pension, £450 a year; and after the commencement of the twenty-fifth year's service for pension, £500 a year. 3. Leave in India, but for the period of one year only, on full military pay and half the staff salary of appointment. No extension of leave involving absence from duty for more than two years, whether taken in or out of India, can be granted except on specially urgent grounds and without pay. An officer unable on account of t state of his health to return to duty within the maximu period of two years' absence, unless he is specially grant an extension of leave without pay, is placed on tempora half-pay or the retired list, as the circumstances of the ca may require. An officer is also liable to be placed on hal pay or the retired list should his health require an und amount of leave, whether in or out of India Leave may granted at any time, but solely at the discretion of t Commanders-in-Chief or of the Local Governments in Ind in the case of officers not under the direct orders of Commander-in-Chief. Officers of the Administrative grad may be granted one period of leave not exceeding eig months during their tenure of appointment. An officer leave is required to join at once on being recalled to dut unless certified by a medical board as unfit to do so.

Naval Medical Service.—A candidate must be between t ages of twenty-one and twenty-eight, and must be the so of parents of pure European blood. He must declare h readiness for general service at home or abroad and mus be free from organic or other disease. Candidates wi be examined by the Board in the following compulsor subjects: (*a*) Medicine, including Therapeutics and Disease of Women and Children, 1200 marks; (*b*) Surgery, 120 marks; (*c*) Anatomy and Physiology, 600 marks; an (*d*) Chemistry and Materia Medica, 600 marks. No can didate is considered eligible who does not obtain one third of the maximum marks in each of the com pulsory subjects. The attention of candidates is especi ally drawn to the importance of the section of Opera tive Surgery as a competent knowledge in this subject is essential in order to qualify for a commission Candidates may be examined in the following voluntar subjects: Zoology, 300 marks; Botany, 300 marks; Physics, 300 marks; Geology and Physical Geography, 300 marks (no candidate will be allowed to present himself for examination in more than two of these subjects); the regulations for the examination clearly set forth the scope of the examination in the Natural Sciences; French and German (200 each), 400 marks. A number less than one third of the marks obtainable in each of these voluntary subjects will not be allowed to count in favour of a candidate who has qualified in the compulsory subjects. The appointments announced for competition will be filled up from the list of qualified candidates, arranged in the order of merit, as finally determined by the total number of marks each has obtained in both the compulsory and voluntary subjects, but should it at any time be considered expedient to grant commissions beyond those periodically competed for it will be competent for the Board of Admiralty to admit annually one candidate proposed by the governing bodies of public schools of medicine in the United Kingdom, or attached to such Colonial Universities as they may think proper, the candidate so proposed to be approved by the Director-General of the Medical Department of the Navy and to be certified by the governing body proposing him to be duly qualified according to the regulations in force for the entry of candidates. Candidates from schools at home will be required to pass a physical and test examination in London which will be arranged for by the Medical Director General. Colonial candidates will have to pass a physical and test examination before a Board of Naval Medical Officers on the station. Successful candidates immediately after passing the examination will receive commissions as surgeons in the Royal Navy and will undergo a course of practical instruction in Naval Hygiene, &c., at Haslar Hospital. Three prizes of the approximate value of £10 each will be awarded at the close of each session at Haslar to the students who have shown the greatest proficiency. The seniority of surgeons on entry will be determined by the sum total of the marks they obtain at the London examination and those at the conclusion of the Haslar course, and their names will then be placed in the Official Navy List. Surgeons entered without competition will take seniority next after the last surgeon entered at the same time by competition. Surgeons are promoted to be Staff Surgeons after twelve years from date of entry, provided they pass the requisite examination after completion of eight years' service from the date of entry; and Staff Surgeons to Fleet Surgeons after twenty years' service if recommended by the Director-General. Deputy Inspectors-General are promoted by selection for ability and merit from the Fleet Surgeons, and Inspectors General from the Deputy Inspectors-General having three years' foreign service, or four years' mixed, of which not less than two must have been abroad, or five years' home service in such appointments as preclude foreign service, provided they have not refused to go abroad when called upon to do so. Special promotions will be made, at their lordships' discretion, from Surgeon to Staff-Surgeon and from Staff-Surgeon to the rank of Fleet-Surgeon, in cases of distinguished service or conspicuous professional merit. Inspectors and Deputy Inspectors-General are retired compulsorily at 60 years of age (except that if in any particular case the Lords Commissioners of the Admiralty may consider that the interests of the public service will be materially advanced by the further retention of an Inspector-General on the active list, the age for retirement of such Inspector-General may be extended to 62 years of age) and other grades at 55 years of age, and all ranks at any time if an officer has not served for five years. In calculating service for retired pay time on half-pay [illegible] one-third service on full-pay. [illegible] till the age of 55 years to serve in time of declared national emergency in a rank not lower than that held on retirement.

The following tables, showing the rates of pay and half-pay of the three branches, will probably be acceptable to students who entertain any intention of entering the public service:—

* If the health of a surgeon breaks down before he completes eight years' service, even if [illegible] due to climatic causes, [illegible] list, receiving a gratuity [illegible] service. This point should be well noted, as it is a most unjust one.

† Including proportion of half pay time.

The half pay, retired pay, and gratuities on retirement are liable to reduction in cases of misconduct.

When an officer retires or withdraws on a *gratuity* his widow and children will have no claim to pension or compassionate allowance.

The hospital allowances for Medical Officers at home and abroad in lieu of provisions for themselves and servants and for fuel and light are as follows:—

Rank.	At home.	Abroad.
	£	£
Inspector-Generals of Hospitals	85	130
Deputy Inspector Generals	67	112
Fleet Surgeons and Staff Surgeons	53	112
Surgeons	39	108

Medical officers serving afloat receive an allowance of 1*s.* 6*d.* a day in lieu of provisions, fuel, and lights, as laid down in the King's Regulations.

The allowance of 5*s.* a day, in addition to full pay, at present granted to the Fleet Surgeon of a flag ship bearing the flag of a Commander in-Chief on a foreign station, will be given to the senior medical officer of such ship, being a Fleet or Staff Surgeon; and an allowance of 2*s.* 6*d.* a day to the senior medical officer, being a Fleet or Staff Surgeon, of the ship of a Commodore or of a senior officer commanding a foreign station.

Candidates will do well to notice that the regulations issued to applicants do not put any limit on the amount of half-pay service which they may be compelled to undergo.

Surgeons who have been kept away from England and from naval hospitals in consequence of lengthened periods of service abroad may, if the convenience of the service will admit, be allowed to attend metropolitan hospitals for three months to improve their professional knowledge, and while so employed they will be borne on ships' books and receive the ordinary pay of their rank; but the number is not to exceed 20 in each year.

INDIAN MEDICAL SERVICE.[§]

The rate of pay drawn by Lieutenants from the date of passing the final examination at the Army Medical School until arrival in India is 10*s.* a day.

Pay at the above rate is issued in this country up to the date of embarkation, and an advance of two months' pay at the same rate is also made prior to embarkation, which is adjusted in India.

The following are the rates of "Indian pay and allowances" which will be drawn by officers hereafter appointed to the Indian Medical Service:—

Rank.	Years' service.	Indian pay and allowance per mensem.	
		When not holding an appointment carrying higher pay.	
		Rs. a. p.	
Lieutenant-Colonel (Senior)		900 0 0	
Lieutenant-Colonel ..	25 and over	888 12 0	
Lieutenant-Colonel ..	20 "	852 3 7	
Major	15 "	677 6 11	
"	12 "	640 14 6	
		A. When not receiving any staff allowance.	B. When receiving staff allowance in addition.
		Rs. a. p.	Rs. a. p.
Captain	10 "	500 0 0	450 0 0
"	5 "	450 0 0	400 0 0
Captain and Lieutenant	under 5	350 0 0	300 0 0

On first appointment they will only come into receipt of "Indian pay and allowances" from the date of their arrival in India.

Officers holding the principal administrative appointments and substantive military charges of the Indian Medical Service receive at present the following consolidated salaries:—

	Rs. per mensem.	
Surgeon-General	2700 to 2200	
Colonel	from ... 2250 to ... 1800	
Lieutenant Colonel in substantive charge of a native regiment	1000 or 1100 with Rs 90 horse allowance in cavalry regiments.	
Major in substantive charge of ditto	800 with Rs. 90	ditto.
Captain above 5 years' full pay service in substantive charge of a native regiment	600 with Rs. 60	ditto.
Captain or Lieutenant under 5 years' ditto in substantive charge of a native regiment..	450 with Rs 60	ditto.

The salaries of other substantive medical appointments in the Civil and Military Departments are consolidated and vary from Rs. 1800 to Rs. 400 per mensem.

Medical charges are of two kinds—substantive and officiating. The first is held by an officer as his fixed permanent appointment. For this he is entitled to the monthly consolidated pay as above shown. An officiating charge is held by an officer who is acting temporarily in an appointment during the absence of an officer whose substantive charge it is. The officer thus officiating receives not the consolidated pay of the appointment, but the Indian pay allowances of his own grade, plus half the staff pay of the appointment in which he is officiating (plus half the staff pay of his own appointment, if he have one). The staff pay of an appointment is the difference between the Indian pay and allowances and the consolidated pay of the permanent incumbent. The extra allowance for an officiating charge cannot be less than Rs. 100 a month.

Qualified officers of the Medical Service are also eligible for appointments in the Assay Department. The salaries of these appointments are from Rs. 600 to Rs. 2250 per mensem.

Officers are required to perform two years' regimental duty in India before they can be considered eligible for civil employment.

Except in the administrative grades and in certain special appointments officers are not debarred from taking private practice as long as it does not interfere with their proper duties.

Under present arrangements officers who are not statutory natives of India receive exchange compensating allowance, to compensate them for the fall of the value of the rupee. The allowance consists of an addition to their salaries equal to half the difference between their salaries converted at (1) 1*s.* 6*d.* the rupee, and (2) the average market rate for each quarter.

RETIRING PENSIONS AND HALF PAY.

Officers of the Indian Medical Service will be allowed to retire on the following scale of pension, on completion of the required periods of service:—

After 30 years' service for pension	£700 per annum + £350 after 5 years' active employment in India as a Surgeon-General, or + £250 per annum after 5 years' active employment as a Colonel.
" 25 " " "	£500 per annum.
" 20 " " "	£365 "
" 17 " " "	£292 "

Time (not exceeding one year) passed on temporary half pay reckons as service for promotion and pension, in the case of an officer placed on half-pay on account of ill-health contracted in the performance of military duty.

Officers of the Indian Medical Service are liable after retirement on pension before completing 30 years' service, to recall to military duty in case of any great emergency arising, up to 55 years of age.

All officers of the rank of Lieutenant-Colonel and Major are placed on *the retired list at the age of 55, and all Surgeons-General* and Colonels at the age of 60.

Officers not entitled to pension, when placed on temporary or permanent half pay, will be granted the British rate of half-pay of their military rank, as under:—

Rank.	Rates of Half-pay.[||] Per diem.	Per annum.
	s. *d.*	£ *s.* *d.*
Lieutenant-Colonel (Senior)	11 0	200 15 0
Lieutenant-Colonel		
Major	9 6	173 7 6
Captain	7 0	127 15 0
Lieutenant	3 0	54 15 0

INVALID PENSIONS.

An officer who has become incapacitated for further service in India on account of unfitness caused by duty may, after he has been two years on temporary half pay, be granted an Invalid Pension on the following scale:—

	Per annum.
After 16 years' pension service	£272
" 15 " " "	252
" 14 " " "	232
" 13 " " "	212
" 12 " " "	192

WOUND PENSIONS.

Officers are entitled to the same allowances on account of wounds and injuries received in action as are granted to combatant officers of His Majesty's Indian Military Forces holding the corresponding military rank.

FAMILY PENSIONS.

The claims to pension of widows and families of officers are treated under the provisions of such Royal Warrant regulating the grant of pensions to the widows and families of British officers as may be in force at the time being.

The widows and families of officers are also entitled to pensions under the Indian Service Family Pension Regulations, for the benefits of which all officers must, as a condition of their appointment, subscribe from the date of their arrival in India.

HONOURS AND REWARDS.

Officers of the Indian Medical Service are eligible for the military distinction of the Order of the Bath and for other Orders, British and Indian, and for good service pensions. Six of the most meritorious officers are named Honorary Physicians and six are named Honorary Surgeons to His Majesty.

[§] No staff or regimental allowance can be drawn until the lower standard examination in Hindustani has been passed. As many lieutenants have been sent to the frontier immediately on arriving in India they have found it impossible to study and pass this examination, and have consequently been doing regimental and other work for Rs. 350 a month. Lately a concession has been granted to medical officers so situated on the frontier, but the rule is still most illiberal and requires alteration.

[||] Officers cannot retire *in India* on half-pay (No. 46, Feb. 28th, 1895).

METROPOLITAN MEDICAL SCHOOLS.[1]

[illegible]

and are provided with rooms and receive a salary of £80 a year. Two assistant anæsthetists are appointed annually, and receive salaries of £120 and £100 respectively, with rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. Two assistant electricians are appointed every six months. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers [illegible] the out-patients, and the [illegible] are chosen from the stud[illegible] now free.

A college is attached to the hospital, in which students can reside subject to the college regulations.

The Medical School Buildings include three large lecture theatres, a large dissecting room, a spacious library (containing [illegible] physi[illegible] and [illegible] the m[illegible] for cl[illegible] public health, and biology, giving ample accommodation in every department.

A ground of ten acres has been purchased by the school committee at Winchmore-hill for the use of the Students' Amalgamated Clubs, and all students are expected to become members.

Instruction in Preliminary Science is given to University of London students in chemistry, biology, and physics throughout the year.

Laboratory Instruction for the D.P.H. is provided during the winter and summer sessions, and elementary instruction in Bacteriology is also given throughout the year.

Staff.—Physicians: Sir William Church, Dr. Gee, Sir Dyce Duckworth, Bart., Dr. Hensley, and Sir Lauder Brunton. Consulting Surgeons: Mr. Holden and Sir T. Smith, Bart. Consulting Ophthalmic Surgeon: Mr. H. Power. Surgeons: Mr. Willett, Mr. Langton, Mr. Marsh, Mr. Butlin, and Mr. Walsham. Assistant Physicians: Dr. Norman Moore, Dr. S. West, Dr. Ormerod, Dr. Herringham, and Dr. Tooth, C.M.G. Assistant Surgeons: Mr. Harrison Cripps, Mr. Bruce Clarke, Mr. Bowlby, C.M.G., Mr. Lockwood, and Mr. D'Arcy Power. Physician Accoucheur: Dr. Champneys. Assistant Physician Accoucheur: Dr. Griffith. Ophthalmic Surgeons: Mr Jessop and Mr. Holmes Spicer. Aural Surgeon: Mr. Cumberbatch. Pathology: Dr. Andrewes. Electrician: Dr. L. Jones. Dental Surgeons: Mr. Paterson and Mr. Ackery. [illegible] Mr. Read and Mr. Ackland. [illegible] Mr. E. Willett. Casualty Physicians: Dr. Langdon Brown and Dr. Thursfield.

This hospital receives within its walls nearly 7000 in-patients annually and its out-patients and casualties amount to more than 160,000 annually. It comprises a service of 744 beds; of these 241 are allotted to the medical cases, 336 to the surgical, including orthopædic cases, 35 [illegible] the eye, 34 to dis[illegible] and 70 at the [illegible] departments have been organised for diseases of the eye, ear, larynx, and skin, as well as for Orthopædic and Dental Surgery. Surgical operations every day at 1.30 P.M. Sur-[illegible]. The physicians [illegible] during both the [illegible]al Lectures on all special subjects are also given. The visits of the [illegible]

Brunton. Surgery: Mr. Walsham and Mr. Bowlby. Clinical Surgery: Mr. Willett, Mr. Langton, Mr. Marsh, Mr. Butlin, and Mr. Walsham. Pathology: Dr. Andrewes. Chemistry: Dr. Chattaway. Descriptive and Surgical Anatomy: Mr. Bruce Clarke and Mr. Waring. Biology: Dr. Shore. Physiology: Dr. E. Klein and Dr. Edkins. Superintendents of Dissections: Mr. Bailey, Mr. Mundy, Mr. Rawling, Mr. Douglas, Mr. Harmer, and Dr. Murphy. Demonstrators of Morbid Anatomy: Dr. Garrod Dr. Fletcher, Mr. Power, and the surgical registrar. Demonstrators of Practical Surgery: Mr. Power and Mr. Waring. Operative Surgery: Mr. Power, Mr. H. J. Waring, and Mr. Bailey. Demonstrators of Practical Physiology: Dr. Edkins, Dr. Langdon Brown, and Dr. Bainbridge. Ophthalmic Demonstrators: Mr. Jessop and Mr. Spicer. Lecturer on Physics: Mr. F. Womack. Practical Chemistry: Dr. Chattaway, Dr. Orton, and Dr. Hurtley.

Summer Session.—Materia Medica and Therapeutics: Dr. Calvert. Midwifery and Diseases of Women and Children: Dr. Champneys. Botany: Rev. G. Henslow. Forensic Medicine: Dr. Hensley. Pathology: Dr. Andrewes. Ophthalmic Surgery: Mr. Jessop. Practical Chemistry: Dr. Chattaway, Dr. Orton, and Dr. Hurtley. Comparative Anatomy: Dr. T. W. Shore. Psychology: Dr. Claye Shaw. Public Health: Dr Hamer. Organic Chemistry: Dr. Chattaway. Demonstrators of Operative Surgery: Mr. Power, Mr Waring, and Mr. Bailey. Morbid Anatomy: Dr. Andrewes, Dr. Garrod. Dr. Fletcher, Mr. Power, and the surgical registrar. Diseases of Skin: Dr. Ormerod. Diseases of the Eye: Mr. Jessop and Mr. Holmes Spicer. Diseases of the Ear: Mr. Cumberbatch Orthopædic Surgery: Mr. Bruce Clarke. Diseases of Larynx: Mr. Bowlby. Demonstators of Medicine: Dr. Herringham, Dr. Tooth and Dr. Horder. Demonstrator of Midwifery: Dr. Robinson. Tutor in Public Health: Dr. Warry. Biological Demonstrators: Dr. Shore, Mr. Williams, and Mr. H. R. Kidner. Bacteriology: *Dr. Andrewes. Pharmacy: Dr. Calvert* and Dr. H. Smith Chemical Physiology: Dr. Edkins. Medical Registrars: Dr. Garrod and Dr. Fletcher. Surgical Registrar: Mr. Waring.

CHARING-CROSS HOSPITAL AND COLLEGE.—This hospital contains 180 beds, a certain proportion of which are set aside for the diseases of children and those special to women. General students are admitted to the practice of the Royal Westminster Ophthalmic Hospital. Total fees, 110 guineas if paid in a single sum on entry, or 121 guineas if paid in five instalments; the sons of Registered Medical Practitioners pay 100 guineas in one sum or 110 guineas in five sums; for Dental students, 54 guineas, or 60 guineas in two equal instalments. General students pay proportionately lower fees, and are admitted without additional fee to the courses of Clinical Medicine and Surgery and to the practice of the Royal Westminster Ophthalmic Hospital. They are entitled to compete for the Scholarships, Gold Medal, Huxley, and Pereira Prizes.

Classes for the Preliminary Scientific Examination of the University of London are held at this Medical School. The fee for the whole course, which begins in October, is 15 guineas. There are also special classes for the practical work for the Department of Public Health and a course in the subject of Diseases of Tropical Climates.

Staff.—Consulting Physicians: Sir J. Fayrer, Bart., M.D., and Sir Guyer Hunter, M D. Consulting Obstetric Physician: Dr. J. Watt Black Consulting Physician for Diseases of the Skin: Dr. Sangster. Physicians: Dr. Green, Dr. Bruce, and Dr. Abercrombie. Physicians to Out-patients: Dr. Willcocks, Dr. Murray,[2] and Dr. Mott. Assistant Physician: Dr. Galloway. Consulting Surgeon: Mr. R. Barwell. Surgeons: Mr. Bloxam, Mr. Morgan, and Mr. Boyd. Surgeons to Out-Patients: Mr. Waterhouse and Mr. Wallis. Assistant Surgeon: Mr. Gibbs. Obstetric Physician: Dr. Amand Routh. Assistant Obstetric Physician: Dr. T. W. Eden. Physician for Diseases of the Skin: Dr. Galloway. Aural Surgeon: Mr. Waterhouse. Orthopædic Surgeon: Mr. Wallis. Throat Physician: Dr. Willcocks. Surgeon Dentist: Mr. J. F Colyer.

Lecturers: Winter Session.—Anatomy: Dr. Christopher Addison. Applied Anatomy: Mr. James Cantlie. Bacteriology: Dr. J. W H Eyre. Biology and Comparative Anatomy: Dr. H W Marett Tims. Chemistry and Physics: Dr. H. Forster Morley and Mr. Percy A. E Richards.

---

[1] For Scholarships see p. 693 et seq.

[2] Dean of the School.

Dental Surgery: Mr. J. F. Colyer. Medicine: Dr. John Abercrombie and Dr. H. Montague Murray. Ophthalmology: Mr. E. Treacher Collins. Physiology: Mr. B. Moore. Practical Anæsthetics: Mr. C. Carter Braine and Mr. H. Bellamy Gardner. Practical Anatomy: Mr. Christopher Addison. Practical Hygiene: Dr. J. W. H. Eyre, Dr. H. Forster Morley, and Mr. Percy A. E. Richards. Practical Medicine: Dr. James Galloway and Dr. W. Hunter. Practical Midwifery: Mr. T. W. Eden. Practical Physiology: Mr. B. Moore. Practical Surgery: Mr. F. C. Wallis. Psychological Medicine: Dr. Percy Smith. Surgery: Mr. Stanley Boyd. Tropical Medicine: Dr. Patrick Manson.

Summer Session.—Anatomy: Mr. Christopher Addison. Applied Anatomy: Mr. James Cantlie. Anæsthetics: Mr. C. Carter Braine and Mr. H Bellamy Gardner. Dental Surgery: Mr. J. F. C lyer. Forensic Medicine: Dr. James Galloway. Materia Medica and Practical Pharmacy: Dr. F. Willcocks. Midwifery: Dr. Amand Routh. Operative Surgery: Mr. Charles Gibbs. Pathology: Dr. F. W. Mott. Pharmacology and Therapeutics: Mr. F. Willcocks. Practical Anatomy: Mr. Christopher Addison. Practical Chemistry: Dr. H. Forster Morley and Mr. Percy A. E. Richards. Practical Medicine: Dr. James Galloway and Dr. W. Hunter. Practical Physiology: Mr. B. Moore. Practical Surgery: Mr. F. C. Wallis. Public Health: Dr. B. A. Whitelegge and Dr. H. T. Bulstrode. Toxicology: Dr. H. Forster Morley and Mr. Percy A. E. Richards.

ST. GEORGE'S HOSPITAL.—This hospital contains 356 beds, of which 205 are allotted to surgical and 146 to medical cases. One ward is set apart for Diseases peculiar to Women. Children's beds are placed in all the women's wards. Two wards are allotted to ophthalmic cases.

Students may become Perpetual Pupils by payment of £150 on entering, or of £160 in four annual instalments. Perpetual pupils are entitled to perpetual admission to lectures and demonstrations as well as to the entire medical and surgical practice of the hospital; they may compete for all prizes and exhibitions, may become clinical clerks during six months and dressers during another six months, or longer if required, without fee, may attend midwifery practice, and may compete for all hospital and school appointments without extra charge. Four house surgeoncies and four house physiciancies, and the salaried offices of obstetric assistant, senior and junior anæsthetists, medical registrars (2), surgical registrar, curator and assistant curator of the Museum, besides demonstratorships and a number of junior hospital appointments, are open to perpetual pupils. Students not being perpetual pupils are admitted to lectures, demonstrations, and hospital practice on payment of £50 annually for two years and £20 annually for succeeding years. Such students may become Perpetual in their third year if they wish and if their conduct has been satisfactory

Staff.—Consulting Physicians: Sir Henry A. Pitman, Dr. J. W. Ogle, Dr. Dickinson, and Dr. Whipham. Consulting Surgeons: Mr. Holmes, Mr. Pick, and Mr. Haward. Consulting Obstetric Physician: Dr. Barnes. Consulting Ophthalmic Surgeon: Mr. Brudenell Carter. Consulting Aural Surgeon: Sir W. B. Dalby. Consulting Dental Surgeon: Mr. Augustus Winterbottom. Physicians: Dr. Ewart, Dr. Isambard Owen. Dr. Penrose, and Dr. R lleston. Obstetric Physician: Dr. Dakin. Assistant Physicians: Dr. Lee Dickinson, Dr. Cyril Ogle, and Dr. Latham. Assistant Obstetric Physician: Dr. Stabb. Physician to the Skin Department: Dr. Wyndham Cottle. Surgeons: Mr. W. H. Bennett, Mr. Dent Mr. G. R. Turner, and Mr. Sheild. Ophthalmic Surgeon: Mr. Adams Frost. Assistant Surgeons: Mr. Herbert Allingham, Mr. Jaffrey, and Mr. Pendlebury. Assistant Ophthalmic Surgeon: Mr. Grimsdale. Surgeon to the Orthopædic Department: Mr. Jaffrey. Surgeon to the Throat Department: Mr. Sheild. Aural Surgeon: Mr. Bull. Dental Surgeon: Mr. Henry Albert.

Lecturers.—Baillie Lecturer in Physic: Dr. Dickinson. Hunterian Lecturer in Surgery: Mr. Holmes. Clinical Medicine: The Physicians to the Hospital. Clinical Surgery: the Surgeons to the Hospital. Principles and Practice of Physics: Dr. Isambard Owen[3] and Dr. Penrose. Tropical Medicine: Mr. Patrick Manson. Test Examiner in Medicine: Dr. Cyril Ogle. Principles and Practice of Surgery: Mr. Dent[4] and Mr. Turner. Midwifery and Diseases of Women and Children: Dr. Dakin. Midwifery and Diseases of Women and Children: Dr. Stabb. Vaccination: Mr. E. Climson Greenwood. Insanity: Dr. Blandford. Clinical Instructor in Insanity: Dr. Alexander. Ophthalmic Surgery: Mr. Adams Frost. Ophthalmic Surgery: Mr. Grimsdale. Diseases of the Skin: Dr. Wyndham Cottle. Aural Surgery: Mr. Bull. Dental Surgery: Mr. Henry Albert. Practical Medicine: Dr. Latham. Practical Surgery: Mr. Pendlebury. Operative Surgery: Mr. Allingham. Hygiene: Dr. Louis Parkes. Forensic Medicine and Toxicology: Dr. Lee Dickinson. Toxicological Chemistry: Mr. Gardner. Pathology: Dr. Rolleston. Bacteriology: Dr. Slater. Pharmacology and Therapeutics: Dr. Cyril Ogle. Anatomy: Mr. Jaffrey.[5] Physiology and Histology: Dr. Buckmaster. Teacher of Anæsthetics: Dr. Menzies. Teacher of Skiagraphy: Mr. Addyman. Assistant Teachers of Anæsthetics: Dr. Blumfield and Dr. Powell. Curator of the Museum and Demonstrator in Morbid Anatomy: Dr. Fenton. Assistant Curator of the Museum: Dr. Trevor. Assistant Teacher of Bacteriology: Dr. Harold Spitta. Demonstrators in Anatomy: Mr. Howell Evans, Mr. Frazer, and Mr. Barwell. Assistant Demonstrators in Anatomy: Mr. Byam, Mr. Matson, and Mr. Courtney. Demonstrator in Chemistry: Mr. Addyman. Demonstrator in Materia Medica: Mr. Stark. Librarian: Mr. Alfred Lowe.

GUY'S HOSPITAL.—This hospital, founded by Thomas Guy in 1721 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 690 beds, and, with its extensive buildings and grounds, occupies an area of about six acres. The hospital is divided into Medical, Surgical, Clinical, Ophthalmic, and Gynæcological wards, independently of separate rooms for special cases.

House physicians, house surgeon, assistant house physicians and assistant house surgeons, obstetric residents, gynæcological assistants, clinical assistants, clerks to anæsthetists, surgeons' and assistant surgeons' dressers, surgical ward clerks, clinical clerks, post-mortem clerks, extern obstetric attendants, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the medical staff, according to merit and without extra payment. The house physicians, of whom there are four, hold office for six months each. The assistant house physicians, who hold office for three months, attend in the out-patient department four afternoons in the week, and see all the cases not seen by the assistant physician of the day. The house physicians have the care of the patients in the medical wards and attend to all emergencies arising in the absence of the physicians. They are provided with board and lodging in the college free of expense. The house surgeons, of whom there are four, hold office for six months each, and are provided with board and lodging in the college free of expense. The Surgical Casualty Department is in charge of two assistant house surgeons. The surgeons' dressers are selected from those students who have completed their third winter session and have been most diligent in the junior appointments. They hold office for three or six months. Six are attached to each surgeon, and during their weeks of special duty they are provided with board and lodging in the hospital free of expense. The obstetric residents, four in number, are provided with board and lodging in the college free of expense.

Higher Examinations.—Classes are held throughout the year for the Preliminary Scientific Examination of the University of London; and special courses of instruction are provided for students preparing for the Primary and Final Fellowship examination and the intermediate M.B. examinations of Oxford, Cambridge, and London. Two courses of Laboratory instruction for candidates for a Diploma in Public Health are given annually.

The College.—The College stands upon a site fronting the east gate of the hospital and is connected with it by a subway. The building serves as a Residential College for Students and at the same time provides accommodation for the Students' Club. The Clubs' Union ground is less than twenty-five minutes' journey from the hospital.

Staff.—Consulting Physicians: Sir Samuel Wilks, Dr. F. W. Pavy, Dr. P. H. Pye Smith, and Dr. J. F. Goodhart, Physicians and Assistant Physicians: Dr. Frederick Taylor,

Dr. W. Hale White, Dr. G. Newton Pitt, Dr. E. C. Perry, Dr. L. E. Shaw, Dr. J. W. Washbourn, Dr. J. H. Bryant, and Dr. J. Fawcett.[6] Consulting Surgeons: Dr. J. Birkett and Mr. Thomas Bryant. Surgeons and Assistant Surgeons: Mr. H. G. Howse, Mr. R. Clement Lucas, Mr. C. H. Golding-Bird, Mr. W. H. A. Jacobson, Mr. Charters J. Symonds, Mr. W. Arbuthnot Lane, Mr. L. A. Dunn, Mr. A. D. Fripp, and Mr. F. J. Steward. Consulting Obstetric Physician: Dr. H. Oldham. Obstetric Physicians: Dr. A. L. Galabin and Dr. B. Horrocks. Assistant Obstetric Physician: Mr. J. H. Targett. Physician for Mental Diseases: Dr. G. H. Savage. Aural Surgeon: Mr. W. Laidlaw Purves. Dental Surgeons: Mr. F. Newland-Pedley, Mr. W. A. Maggs, and Mr. J. H. Badcock. Ophthalmic Surgeons: Mr. C. Higgens and Mr. W. A. Brailey. Instructor in Anæsthetics: Mr. Tom Bird. Anæsthetists: Mr. G. Rowell, Dr. H. F. Lancaster, Mr. C. J. Ogle, Dr. W. S. Handley, and Mr. R. H. J. Swan Medical Registrar and Tutor: Dr. A. J. Cleveland. Surgical Registrar and Tutor: Mr. G. S. Simpson. Obstetric Registrar and Tutor: Mr. G. Bellingham Smith. Ophthalmic Registrar and Tutor: Mr. A. W. Ormond. Warden of the College: Mr. Dunn. Lying-in Charity: Dr. Horrocks and Mr. Targett.

Lecturers.—Clinical Medicine: the Physicians and Assistant Physicians. Clinical Surgery: the Surgeons and Assistant Surgeons. Medicine: Dr. Taylor and Dr. Hale White. Practical Medicine: Dr. Cleveland. Surgery: Mr. Howse and Mr. Lucas. Operative Surgery: Mr. Fripp and Mr. Steward. Practical Surgery: Mr. Simpson. Midwifery and Diseases of Women: Dr. Galabin. Practical Obstetrics: Mr. Targett. Mental Diseases: Dr. Savage. Ophthalmic Surgery: Mr. Higgens. Dental Surgery: Mr. Newland-Pedley. Aural Surgery: Mr. Laidlaw Purves. Diseases of the Skin: Dr. Perry. Diseases of the Throat: Mr. Symonds. Electro-Therapeutics: Dr. Bryant. Anæsthetics: Mr. Tom Bird and Mr. Rowell. Hygiene and Public Health: Dr. Sykes and Mr. Pakes. Pathology: Dr. Pitt. Morbid Anatomy: Dr. Bryant and Dr. Fawcett. Morbid Histology and Bacteriology: Mr. [illegible] Smith and Mr. Pakes. [illegible] ases: Dr. Fawcett and [illegible] ashbourn and Mr. Pakes. [illegible] Anatomy: Mr. Lane and Mr. Dunn. Practical Anatomy: Mr. Fagge, Mr. Rowlands, and Mr. Swan. Physiology: Dr. Washbourn and Dr. Pembrey. [illegible] Dr. Beddard, and Dr. [illegible] peutics: Dr. Perry. [illegible] Dispenser-Chemistr[illegible] Mr. Wade, Mr. Ryffel, and Mr. Ball. Experimental Physics: Professor Reinold, F.R.S., and Mr. Ball. Biology: Dr. Stevens and Mr. Swan. Psychology: Dr. Savage and Dr. Hyslop.

KING'S COLLEGE.—The hospital contains 217 beds in use The composition fees are £135 if paid in one sum or £148 if paid in four instalments. Resident medical officers have rooms at the hospital and commons free; they are selected by examination and hold their appointment for six months or a year. There are three house physicians, two physician accoucheur assistants, and three house surgeons. Sambrooke registrarships, value £50 per annum, are tenable for two years. Clinical assistants senior and junior of the special departments—ophthalmic, ear, and throat. Senior dressers and dressers, clinical clerks, assistant demonstrators of anatomy and physiology, and prosectors are elected by examination, and in consideration of their former work in the medical school as matriculated students. Classes for the science subjects required by the University of London are held by the Professors of the Science Faculty of King's College, and students avail themselves of their laboratories.

Laboratories.—Chemistry, Physiology, Pharmacology, Bacteriology, State Medicine, Pathology, and Neuro-pathology have special laboratories.

Resident Chambers.—There are chambers at King's College available for a limited number of students; rent, including dinner during terms, from £50 to £60 a year.

Athletic Club.—All students are entitled to the privileges of the Athletic Club, which manages a large recreation ground of the College at Wormwood Scrubbs.

Staff.—Consulting Physicians: Sir A. B. Garrod, Dr. Lionel S. Beale, Dr. W. S. Playfair, Dr. Alfred B. Duffin, and Dr. I. Burney Yeo. Consulting Surgeon: Lord Lister. Physicians: Dr. David Ferrier, Dr. John Curnow, Dr. Nestor Tirard, Dr. Norman Dalton, and Sir Hugh Beevor, Bart. Surgeons: Mr. William Rose, Mr. W. W. Cheyne, Mr. A. B. Barrow, Mr. A. Carless, and Mr. F. F. Burghard. Assistant Physicians: Dr. Raymond Crawfurd[7] and Dr. W. Aldren Turner. Obstetric Physician: Dr. T. C. Hayes. Assistant Obstetric Physician: Dr. John Phillips. Assistant Physician for the Diseases of Children: Dr. George F. Still. Diseases of the Throat: Dr. Greville MacDonald. Assistant Surgeons: Dr. G. L. Cheatle and Mr. P. T. B. Beale. Dental Surgeon: Mr. A. S. Underwood. Assistant Dental Surgeon: Mr. C. E Wallis. Ophthalmic Surgeon: Mr. M. M. McHardy. Assistant Ophthalmic Surgeon: Mr. L. V. Cargill. Aural Surgeon: Mr. Urban Pritchard. Assistant Aural Surgeon: Mr. Arthur H. Cheatle. Assistant Physician for Diseases of the Skin: Dr. A. Whitfield. Pathological Registrar: Dr. Norman Dalton. Physician in charge of Electrical Department: Dr. W. Aldren Turner. Medical Officer in charge of X-ray Department. Dr. F. Harrison Low. Anæsthetist and Instructor in Anæsthetics: Dr. J. F. W. Silk. Senior Medical Registrar and Tutor: Dr. R. M. Leslie. Senior Surgical Registrar and Tutor: Dr. T. Percy Legg. Obstetric Registrar and Tutor: Dr. Hugh Playfair. Sambrooke Registrars: Mr. J C. Briscoe and Mr. M. S. Mayou. Clinical Pathologist: Dr. O. F. F. Grünbaum.

Lecturers.—Anatomy, Descriptive and Surgical: Dr. A. Robinson (Professor) and Dr. G. J. Jenkins (Demonstrator). Phy[illegible] Elementary Biology: Dr. [illegible] T. B. Beale (Demonstra[illegible] e (Demonstrator of Physiology), Mr. P. T. B. Beale (Lecturer in Elementary Biology), and Dr. H. W. Lyle (Lecturer in Animal Biology). Chemistry and Practical Chemistry: Dr. J. M. Thomson (Professor), Mr. Herbert Jackson (Lecturer), and Mr. P. H. Kirkaldy (Demonstrator). Experimental Physics: Dr. W. G. Adams (Professor) and Mr. E. F. Herroun (Demonstrator). Botany (Vegetable Biology): Dr. W. B. Bottomley (Professor), and Mr. E. J. Schwartz (Demonstrator). Medicine (Principles and Practice of): Dr. Nestor Tirard (Professor). Neuro-Pathology: Dr. D. Ferrier (Professor) and Dr. W. A. Turner (Demonstrator). Psychological Medicine: Dr. Ernest W. White (Professor). Surgery (Principles and Practice of): Mr. W. W. Cheyne (Professor). Surgery (Operative): Mr. A. Carless (Teacher). Surgical Pathology: Mr. G. L. Cheatle (Teacher). Materia Medica and Pharmacology: Dr. F. W. Tunnicliffe (Professor). Obstetric Medicine and Diseases of Women and Children: Dr. T. C. Hayes (Professor). Practical Obstetrics: Dr. John Phillips (Lecturer). Diseases of Children: Dr. G. F. Still (Assistant Physician). Pathology: Dr. N. Dalton (Professor). Forensic Medicine: Dr. W. R. Smith (Professor). Hygiene: Dr. W. J. R. Simpson (Professor). State Medicine Laboratory: Dr. W. R. Smith (Director) and Mr. E. Russell (Demonstrator). Bacteriology: Dr. E. M. Crookshank (Professor). Clinical Medicine: Dr. John Curnow. Clinical Surgery: Dr. W. Rose (Professor). Ophthalmic Surgery: Mr. M. M. McHardy Professor). Aural Surgery: Dr. U[illegible] Anæsthetics: Dr. J F. W. Silk. [illegible] Underwood (Professor). Diseas[illegible] Whitfield (Assistant Physician).

LONDON HOSPITAL AND COLLEGE.—The hospital has nearly 800 beds in constant use and no beds are closed. Being the only general hospital for East London—i.e., for a million and a half people—the practice is immense. In-patients last year 12,746; out-patients, 161 762; accidents, 19,944; major operations, 2526. Owing to the enormous number of patients more appointments are open to students than at any other hospital. Receiving-room officers, house physicians, house surgeons, &c.: 60 of these qualified appointments are made annually and more than 150 dressers, clinical clerks, &c., appointed every three months. All are free to students of the College. Holders of resident appointments have free board. Twenty-nine scholarships and prizes are given annually. Five entrance scholarships, £120, £60, £35, £30, £20, are offered in September. Special classes are held for the University of London and other higher examinations. Special entries for medical and surgical practice can be made. Qualified practitioners will find excellent opportunities for studying the rarest diseases. Lectures and classes are held throughout the year to suit the requirements of candidates desirous of obtaining the Diploma in Public Health. These courses are recognised both by the Universities of Oxford and Cambridge and by the Examining Board in England. A reduction of 15 guineas is made to the sons of members of the profession. The new laboratories and class-rooms for Bacteriology, Public Health, Operative Surgery, Chemistry, and Biology are now in full use. The new Clubs Union Rooms, Garden, and Fives Court are now open. The Clubs Union Athletic Ground is within easy reach of the hospital. The Metropolitan and other railways have stations close to the hospital and the college.

---

[6] Dean of the Medical School.

[7] Dean of hospital for 1901-2.

[8] Dean of the school.

Staff.—Consulting Physicians: Dr. Hughlings Jackson and Dr. Fenwick. Consulting Surgeons: Mr. Hutchinson, Mr. Couper, Mr. McCarthy, and Sir Frederick Treves. Physicians: Dr. Stephen Mackenzie, Dr. A. E. Sansom, Dr. Gilbart-Smith, Dr. Francis Warner, and Dr. Percy Kidd; Dr. Frederick J. Smith, Dr. W. J. Hadley, and Dr. G. Schorstein (with care of out-patients). Assistant Physicians: Dr. Bertrand Dawson, Dr. Henry Head, and Dr. Robert Hutchinson. Surgeons: Mr. Waren Tay, Mr. C. W. Mansell-Moullin, Mr. Hurry Fenwick, Mr. F. S. Eve, and Mr. J. Hutchinson, jun.; Mr. T. H. Openshaw and Mr. H. P. Dean (with care of out-patients. Assistant Surgeons: Mr. A. B. Roxburgh, Mr. P. Furnivall, and Mr. H. Barnard. Obstetric Physicians: Dr. G. E. Herman and Dr. Lewers (with care of out-patients). Physician to the Skin Department: Dr. Stephen Mackenzie. Consulting Dental Surgeon: Mr Barrett Consulting Anæsthetist: Dr. Hewitt. Surgeons to the Ophthalmic Department: Mr. Waren Tay and Mr. A. B. Roxburgh. Senior Surgeon to the Aural Department: Dr. Edward Woakes. Surgeon to the Aural Department: Mr. T. Mark Hovell. Medical Officer in charge of the Electrical Department: Dr. W. S Hedley. Analyst to the Hospital: Mr. Hugh Candy. Bacteriologist to the Hospital: Dr. W. Bulloch. Dental Surgeons: Mr. Dolamore and Mr. Farmer. Anæsthetists: Dr. Probyn Williams, Mr. Hilliard, and Mr. Clapham.

Lecturers.—Medicine: Dr. Percy Kidd. Clinical Medicine: the Physicians and Assistant Physicians. Surgery: Mr. C. W. Mansell-Moullin. Clinical Surgery: the Surgeons and Assistant Surgeons. Anatomy: Dr. T. H. Openshaw and Dr. A. Keith. Physiology: Dr. Leonard Hill and Dr. J. J. R Macleod. Chemical Physiology: Dr. R. Hutchison. Chemistry: Mr. F. J. M. Page and Mr. Hugh Candy. Pathology—(1) Surgical: Mr. F. S. Eve; (2) Medical: Dr. W. J. Hadley; and (3) General: Dr. W. Bulloch. Midwifery and Diseases of Women: Dr. G. Ernest Herman. Clinical Obstetrics: The Obstetric Physicians Practical Obstetrics: Dr. G. Ernest Herman and Dr. Arthur H. N. Lewers. Forensic Medicine—(1) Public Health: Dr. J. C. Thresh; and (2) Medical Jurisprudence and Toxicology: Dr. Fredk. J. Smith. Public Health and Sanitary Science: Dr. W. Bulloch, Dr. John C. Thresh, and Mr. F. J. M. Page. Mental Diseases: Dr. J. Kennedy Will. Materia Medica and General Therapeutics: Dr. Francis Warner and Dr. Bertrand Dawson. Biology: Dr. P. Chalmers Mitchell and Mr. G. P. Mudge. Experimental Physics: Mr. F. J. M. Page and Mr. Hugh Candy. Ophthalmic Surgery: Mr. A. B. Roxburgh. Aural Surgery: Dr. Edward Woakes. Diseases of the Throat: Mr. T Mark Hovell. Anatomy and Pathology of the Teeth: Mr. H. Dolamore and Mr. F. M. Farmer. Practical Anatomy: Dr Arthur Keith, Mr. H. M. Rigby, and Mr. J. H. Watson. Practical Physiology and Histology: Dr. Leonard Hill and Dr. J. J R. Macleod. Foods and Dietetics: Dr. R. Hutchison. Practical Chemistry: Mr. F. J. M. Page and Mr. Hugh Candy. Operative Surgery: Mr. H. P. Dean. Practical Surgery: Dr. A. B. Roxburgh. Demonstrators of Morbid Anatomy: Dr. F. J. Smith, Dr. W. J. H. Hadley, and Dr. G. Schorstein. Bacteriology: Dr. W. Bulloch and Dr. W. Hunter. Pathological Histology: Dr. W. Bulloch. Therapeutic Electricity and Radiography: Dr. W. S. Hedley. Anæsthetics: Dr. R. J. Probyn-Williams, Mr. H. Hilliard, and Mr. E. W. Clapham. Elementary Clinical Medicine: Mr. Henry Head and Dr. Robert Hutchinson. Medical Tutor: Dr. T. H. Sequeira. Surgical Tutor: Mr. H. L Barnard. Obstetric Tutor: Dr. H. R. Andrews. As Emeritus Professor of Surgery Mr. Hutchinson will give in the Summer Session, and Sir Frederick Treves will give in the Winter Session a course of lectures in Clinical Surgery. The special subjects and the dates will be announced in due course. Dr. Hewitt, as Emeritus Lecturer on Anæsthetics, will give a course of lectures during the first half of the Winter Session. Warden: Mr. Munro Scott.

ST. MARY'S HOSPITAL.—The hospital contains 281 beds, which number will be raised to 381 on completion of the Clarence wing. The situation of the hospital in the centre of the residential districts of Paddington, Bayswater, and North Kensington renders it especially convenient to students who wish to reside in the immediate vicinity, and a register of approved lodgings is kept in the office or the Medical School. All clinical appointments in the hospital are free to students of the Medical School and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers, and two resident anæsthetists are appointed in each year and receive board and residence in the hospital. Entrance scholarships in Natural Science, one of £145, two of £78 15*s.*, one of £52 10*s.*, and two of £63 (open to students from Oxford and Cambridge), are awarded annually by examination in September.

The New Wing.—The new wing, the ground floor of which, comprising the new out-patient department, was opened in 1898, is about to be completed. This will add to the hospital 100 new beds and will include an additional operating theatre, a new clinical laboratory, and an x-ray department.

The Laboratories.—The Physiological Laboratories have recently been enlarged and the Pathological Departmen further extended with the provision of special laboratorie for the study of bacteriology and pathological chemistry.

Special Tuition.—In addition to systematic courses lectures and demonstrations special tuition is provided f the Intermediate and Final Examinations of the Universitie of Oxford, Cambridge, and London without additional fees.

Preliminary Scientific Course.—Special classes, includin lectures and laboratory work, are held throughout the year.

The composition fee for full students is £140 if paid i one sum or £145 if paid in four instalments. Universit students who have completed their examinations in Anatom and Physiology are admitted on payment of a compositio fee of 60 guineas (£63) paid in one sum or by payment o two annual instalments of 35 guineas (£36 15*s.*) and 3 guineas (£31 10*s.*) respectively. University students wh have not completed their examination in Anatomy an Physiology pay an annual fee of 25 guineas (£26 5*s.*) until they have passed these examinations, and then pay the composition fee. Separate courses of lectures, laboratory work, or hospital practice may be taken. The compositio fees include membership of the amalgamated clubs. Th School Calendar and full information can be obtained fro the Secretary, St. Mary's Hospital Medical School, Paddington, W.

Staff.—Consulting Physicians: Sir Edward Sieveking and Sir William Broadbent. Consulting Surgeons: Mr. H. Spencer Smith, Mr. A. T. Norton, Mr. G. P. Field (Aural), Mr. Howard-Hayward (Dental), and Mr. G. Anderson Critchett (Ophthalmic). Physicians: Dr. W. B. Cheadle, Dr. D. B. Lees and Dr. Sidney Phillips. Surgeons: Mr. Edmund Owen, Mr. Herbert W. Page, and Mr. A. J. Pepper. Physicians in charge of Out-Patients: Dr. R. Maguire, Dr. A. P. Luff, and Dr. H. A. Caley. Surgeons in charge of Out-Patients: Mr. A. Q Silcock, Mr. J. Ernest Lane and Mr. H. Stansfield Collier. Physician-Accoucheur: Dr. Montagu Handfield-Jones. Physician-Accoucheur in Charge of Out-Patients: Dr. W. J. Gow. Physician in charge of Children's Department: Dr. Sidney Phillips. Ophthalmic Surgeon: Mr. H. E. Juler. Surgeon to the Skin Department: Mr. Malcolm Morris. Dental Surgeon: Mr. Morton Smale Aural Surgeon: Dr. G. William Hill. Surgeon to the Throat Department: Dr. Scanes Spicer. Administrator of Anæsthetics: Mr. Henry Davis.

Lecturers.—Clinical Medicine: Dr. W. D. Cheadle and Dr. D. B. Lees. Clinical Surgery: Mr. Edmund Owen and Mr. Herbert W. Page. Medicine: Dr. Sidney Phillips. Surgery: Mr. A. J. Pepper and Mr. A. Q. Silcock. Practical and Operative Surgery: Mr. H. Stansfield Collier. Pathology: Dr. Robert Maguire and Mr. H G. Plimmer. Bacteriology: Mr. H. G. Plimmer and Dr. A. Paine. Pathological Chemistry: Dr. W. H. Willcox. Midwifery and Gynæcology: Dr. M. Handfield-Jones. Materia Medica and Therapeutics: Dr. H. A. Caley.[9] Forensic Medicine: Dr. A. P. Luff. Descriptive and Surgical Anatomy: Mr. J. Ernest Lane. Physiology: Dr. A. Waller and Mr. W. Legge Symes (Assistant Lecturer). Demonstrator: Mr. J. H. Wells. Histology: Mr. W. Legge Symes. Biology: Dr. W. G. Ridewood. Demonstrator: Mr. H B. Lacey. Chemistry and Physics:

---

[9] Dean.

Dr. W. H Willcox and Mr. E H. Strange. Hygiene and Public Health: Dr. A. P. Luff and Dr. E J. Steegmann. Mental Diseases: Dr. Theo. B Hyslop. Diseases of the Eye: Mr H. E Juler. Diseases of the Ear: Dr. G. William Hill. Diseases of the Skin: Mr. Malcolm Morris. Diseases of the Throat: Dr. Scanes Spicer. Dental Surgery: Mr Morton Smale. Tropical Diseases: Dr. John Anderson Anæsthetist: Mr. Henry Davis Medical Tutor: Dr. F. H Poynton. Surgical Tutor: Mr. H. Stansfield Collier Obstetric Tutor: Dr. W. J. Gow. Medical Registrar: Dr W. J Harris. Surgical Registrar: Dr. A G. Wilson Electrical Department: Dr. W. J Harris. Curator of the Museum: Dr. R. W. Dodgson. Anatomy: Dr. W. Warren Low and Mr. W. Ashdowne (demonstrators). Chemistry. Mr. E H. Strange (demonstrator). Practical Pharmacy: Mr. E A. Andrews (demonstrator) School Secretary: Mr. B. E. Matthew.

MIDDLESEX HOSPITAL.—The hospital contains 340 beds. There is a special wing for patients suffering from cancer, consisting of four wards, containing 40 beds; here cancer patients are received and attended for a period limited only by the duration of their disease.

Hospital Appointments.—All hospital appointments are allotted to students without any extra fee. Eighteen Resident Appointments are annually filled from the pupils of the hospital, each appointment extending over six months.

Special Classes are held to prepare students for the Inter M.B. (Lond.) Examination and for the Primary Examination for the diploma of F.R.C.S. Eng.

The Hospital and Medical School are fully equipped for the theoretical and practical teaching of all the subjects included in the examinations in Medicine and Surgery in the United Kingdom and for the diploma in Public Health; and ample laboratory and class-room accommodation is provided for the teaching of the various subjects of the curriculum and for original research in Medicine, Pathology, or Bacteriology.

A Residential College to accommodate about 30 students adjoins the hospital. The charge for residence is £8 8*s.*, £7 7*s.*, and £6 6*s.* per term, according to the position of the room Breakfast, luncheon, and dinner are supplied in the College Hall at a very moderate charge.

Fees—The Composition Fee for the entire curriculum is 135 guineas, or 145 guineas if paid in three instalments. The fee for the Dental Curriculum is 54 guineas, or 60 guineas if paid in two instalments. Students who have completed the study of Anatomy and Physiology or passed the London Preliminary Scientific M.B. Examination are received on special terms

Staff.—Consulting Physicians: Dr. Sydney Coupland and Sir R D. Powell. Physicians: Dr. W. Cayley, Dr. J K Fowler, and Dr. W. Pasteur.[10] Obstetric Physician: Dr W. Duncan. Assistant Physicians: Dr. W. E Wynter, Dr A. F. Voelcker, Dr. F. J Wethered, and Dr. H. C Thomson. Consulting Physician to the Skin Department: Dr. R Liveing Physician to the Skin Department: Dr J J Pringle. Assistant Obstetric Physician: Dr. R Boxall Consulting Surgeons: Mr. Nunn and Mr. G. Lawson Surgeons: Mr. Morris, Mr. Clark, and Mr. Gould. Assistant Surgeons: Mr. Bland-Sutton, Mr Murray, and Mr. Kellock Ophthalmic Surgeon: Mr. W. Lang. Aural Surgeon; Mr S Paget. Consulting Surgeon-Dentist: Mr. Turner. Dental Surgeon; Mr. W. Hern. Assistant Dental Surgeon: Mr Nowell. Curator of the Museum and Pathologist Dr Thomson. Registrars: Dr. R A. Young and Mr A Baldwin. Resident Medical Officer: Mr. F. A. Farden. Chloroformists: Mr. Norton, Mr T. G. A. Burns, Mr. H P Noble and Mr Comyns Berkeley

Lecturers—Winter Session: Anatomy: Dr. Thompson Demonstrator: Dr. Gladstone. Biology and Physiology Dr. Young. Demonstrator: Mr Goodall. Chemistry: Dr Kellas. Demonstrator: Mr Froggatt. Medicine: Dr Fowler and Dr. Pasteur. Practical Medicine. Dr. Pasteur. Surgery. Mr. Clark Practical Surgery: Mr. Murray. Operative Surgery: Mr. Kellock. Practical Midwifery: Dr. Boxall Clinical Lectures in Medicine: The Physicians. Clinical Lectures in Surgery: The Surgeons. Clinical Lectures on Diseases of the Ear, Throat, and Nose: Mr. S Paget. Lectures in Ophthalmology: Mr Lang Lectures in Dental Surgery: Mr. Hern. Public Health and Bacteriology: Mr. Foulerton. Summer Session: Pharmacology and Therapeutics: Dr. Wynter. Pathology and Pathological Histology: Dr. Voelcker. Forensic Medicine and Toxicology: Dr. Wethered. [11] Dean.

Parsons, Mr. H. B. Robinson, and Mr. J. H. Fisher. Elementary Biology: Mr. F. G. Parsons. Forensic Medicine and Toxicology: Dr. Cory and Dr. Colman. Midwifery: Dr. Tate. Botany: Mr. A. W. Bennett. Chemistry and Practical Chemistry: Mr. W. R. Dunstan and Dr. Crossley. Mental Diseases: Dr. H. Rayner. Public Health: Dr. E. Seaton. Practical and Manipulative Surgery: Mr. Ballance and Mr. Battle. Practical Physiology: Dr. J. B. Leathes. Comparative Anatomy: Mr. Parsons. Diseases of the Eye: Mr. Lawford. Pathology, Pathological Anatomy and Bacteriology: Dr. Turney, Dr. Perkins, and Mr. Shattock. Pharmacology and Therapeutics: Dr. Mackenzie. Operative Surgery: Mr. Makins, Mr. Battle, and Mr. Ballance. Lectures on Clinical Medicine and Surgery are delivered every Wednesday. Special Departments for the Diseases of Women and Children, and for Diseases of the Eye, Skin, Throat, and Ear. Instruction in Electro-Therapeutics by Dr. Turney. Instruction in Dental Surgery by Mr. Truman. Instruction in Vaccination by Dr. Cory.

UNIVERSITY COLLEGE HOSPITAL LONDON.—*Composition fees.*—1. For the entire medical education required by the Examining Board in England and the Society of Apothecaries, 150 guineas if paid in one sum at the commencement of the course; 155 guineas if paid by instalments, as follows—first year, 70 guineas; second year, 55 guineas; third year, 30 guineas. 2. For those students who do not require to attend Chemistry, Pharmacy, and Elementary Biology at a medical school (under the regulations of the Examining Board in England) the fee will be—135 guineas, if paid in one sum; 140 guineas, if paid by instalments, as follows—first year, 60 guineas; second year, 50 guineas; third year, 30 guineas. 3. For the whole course of instruction for the Intermediate Examination in Medicine of the University of London, 60 guineas (paid in one sum). 4. For the course of instruction for the Final M.B. Examination of the University of London, 80 guineas, if paid in one sum; 82 guineas, if paid by instalments, as follows—first year, 50 guineas; second year, 32 guineas. 5. Composition fee for Dental Students, 65 guineas, or exclusive of Chemistry, Practical Chemistry, Physics, and Materia Medica, 50 guineas. 6. Composition fee for the whole course of instruction for the Preliminary Scientific (M.B.) Examination of the University of London, 25 guineas.

Eight house physicians, six house surgeons, four senior and eight junior obstetric assistants and two ophthalmic assistants are selected annually by examination from among the senior students. The house physicians and house surgeons reside in the hospital for a period of six months, and the senior obstetric assistants for three months, receiving free board and lodging.

Several professors and other gentlemen connected with the College receive students to reside with them; and in the office of the College there is kept a register of persons unconnected with the College who receive boarders into their families; among these are several medical gentlemen and clergymen.

Staff.—Consulting Physicians: Dr. H. C. Bastian, Sir W. R. Gowers, Sir J. Williams, Dr. S. Ringer. Physicians: Dr. F. T. Roberts, Dr. G. V. Poore, Sir Thomas Barlow, Bart., Dr. J. R. Bradford, Dr. S. H. C. Martin, and Dr. J. R. Russell. Obstetric Physician: Dr. H. R. Spencer. Assistant Obstetric Physician: Dr. G. F. Blacker. Physician, Skin Department: Dr. H. R. Crocker. Consulting Surgeons: Sir Henry Thompson, Mr. C. Heath, and Mr. S. J. Hutchinson (Dental). Surgeons: Mr. A. E. Barker, Mr. R. J. Godlee, Mr. V. A. Horsley, Mr. B. Pollard, and Mr. Johnson. Assistant Surgeon: Mr. T. R. H. Bucknall. Ophthalmic Surgeon: Mr. J. Tweedy. Assistant Ophthalmic Surgeon: Mr. P. Flemming. Dental Surgery: Mr. S. Spokes. Anæsthetist: Dr. D. Buxton. Surgeon Registrar: Mr. W. B L. Trotter. Resident Medical Officer: Dr. Charles Bolton.

Lectures of the Faculty of Medicine: Winter Session.—Anatomy: Professor G. D. Thane. Dissections by Mr. Flemming, Mr. G. B. M. White, Mr. P. M. Heath, and E. G. Perodeau. Chemistry: Professor Ramsay. Biology: Professor E. A. Minchin. Principles and Practice of Medicine: Dr. G. Vivian Poore Principles and Practice of Surgery: Professor A. E. Barker Practical and Operative Surgery: Mr. B. Pollard and Mr. R. Johnson. Physiology: Professor E. H. Starling. Dental Surgery: Mr. S. Spokes. Morbid Anatomy and Bacteriology: Dr. S. Martin.

Summer Session.—Materia Medica and Therapeutics: Dr. J. R. Bradford. Pathological Anatomy: Dr. S. Martin. Practical Chemistry: Professor Ramsay. Midwifery and Diseases of Women: Dr. Spencer. Medical Jurisprudence: Dr. J. S. R. Russell. Ophthalmic Medicine and Surgery: Professor J. Tweedy. Operative Surgery: Mr. Pollard. Hygiene and Public Health: Professor Corfield, M.D. Practical Physiology and Histology: Professor E H. Starling. Mental Physiology: Dr. Mickle. Principal of the College: G. Carey Foster. LL.D., F.R.S.

WESTMINSTER HOSPITAL.—The hospital contains upwards of 200 beds. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, for Orthopædics, and for Diseases of Women, and a special ward for Children. The Anatomical Museum is open to the students. There are also Pathological and Materia Medica Museums.

A medical and a surgical registrar, each with a salary of £40, are appointed annually. Two house physicians, two house surgeons, and a resident obstetric assistant are appointed for six months after examination, and are provided with rooms and commons; also two assistant house surgeons with commons only. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among qualified students of the hospital.

Preliminary Scientific.—Special classes are held in the subjects of this examination—Chemistry, Dr. Hake; Physics, Mr Somerville; Biology, Dr. Sherlock. The extra fee to a general student is 12 guineas.

Intermediate M.B.—Advanced Physiology and Histology, Dr. Gossage; Organic Chemistry, Dr. Hake; Materia Medica, Dr. Purves Stewart.

D.P.H.—The course of Laboratory Instruction may now be taken. Physics Mr. Somerville; Chemistry, Dr. Hake; Bacteriology, Dr. Blaxall. Fee: 12 guineas for three months, 20 guineas for six months.

Bacteriology.—A course in General Bacteriology is given by Dr Blaxall. Fee £5 5*s.*

Staff.—Consulting Medical Staff: Dr. H. B. Donkin. Consulting Surgical Staff: Mr. C. Holthouse, Mr. Richard Davy, Mr. G. Cowell, and Mr. F. C. Macnamara. Consulting Dental Surgeon: Dr. J. Walker. Medical In-patient Staff: Dr. W. H. Allchin, Dr. de Havilland Hall, and Dr. W. Murrell. Obstetric Physician: Dr. W. Rivers Pollock. Surgical In-patient Staff: Mr. C. Stonham, Mr. W. G. Spencer, and Mr. A. H. Tubby. Medical Out-patient Staff: Dr. R. G. Hebb, Dr. W. A. Wills, Dr. A. M. Gossage, and Dr. Purves Stewart. Physician for Diseases of the Skin: Dr. T. Colcott Fox. Assistant Obstetric Physician: Dr. G. H. Drummond Robinson. Surgical Out-patient Staff: Mr. P. R. W. De Santi, Mr. W. Turner. and Mr. E. P. Paton. Surgeon in charge of the Throat Department: Mr. W. G. Spencer. Ophthalmic Surgeon: Mr. G. Hartridge. Surgeon in charge of the Orthopædic Department: Mr. A. H. Tubby. Surgeon in charge of the Ear Department: Mr. P. R. W. De Santi. Dental Surgeons: Mr. C. W. Glassington and Mr. E. Gardner. Administrator of Anæsthetics: Dr. N. W. Bourns and Mr. A. MacLeod. Pathologist and Curator of Museum: Dr. W. S. Lazarus-Barlow. Medical Registrar: Dr. B. Abrahams. Surgical Registrar: Mr. F. Canny Ryall. Pharmacist: Mr. A. E. Tanner. Secretary: Mr. S. M. Quennell.

Lectures.—Clinical Medicine: Dr. Allchin, Dr. Hall, and Dr. Murrell. Clincal Surgery: Mr. Stonham, Mr. Spencer, and Mr. Tubby.[12] Clinical Gynæcology: Dr. Pollock.[13] Medicine: Dr. de Havilland Hall and Dr. Murrell. Diseases of the Skin: Dr. Colcott Fox. Neurology and Insanity: Dr. Charles Mercier. Elementary Practical Medicine: Dr. Wills. Surgery: Mr. Stonham. Ophthalmic Surgery: Mr. Hartridge. Surgery of the Throat and Nose: Mr. Spencer. Orthopædic Surgery: Mr. Tubby. Aural Surgery: Mr. de Santi Dental Surgery: Mr. Glassington. Anæsthetics: Dr. Bourns. Operative Surgery: Mr. Stonham. Surgical Anatomy: Mr. Paton. Minor Surgery: Mr. de Santi. Surgical Pathology; Mr. Paton. Midwifery and Diseases of Women: Dr. Pollock. General Pathology and Morbid Anatomy: Dr. Lazarus-Barlow. Post-mortem Demonstrations: Dr. Lazarus. Barlow. Materia Medica, Therapeutics, and Pharmacology: Dr. Purves Stewart. Demonstrator of Practical Pharmacy: Mr. A. E. Tanner. Forensic Medicine:

London (Royal Free Hospital) School of Medicine for Women, 8, Hunter-street, Brunswick-square, W C.—The fee for the whole medical course is £125 in one sum, or £135 in four instalments. This entitles students to attend all necessary lectures and practical classes as well as the medical and surgical practice of the hospital, and to hold clerkships and dresserships in the in-patient and out-patient departments. Students can also attend the in-patient and out-patient practice of the New Hospital for Women. Students *after qualification can hold the post of house physician,* house surgeon, clinical assistant, anæsthetist and assistant anæsthetist, medical and surgical registrar, museum curators and demonstrators in the departments of Anatomy, Physiology, and Chemistry, and two of the resident posts at the Royal Free Hospital, as well as those of the New Hospital for Women, which is officered entirely by medical women.

In addition to the list of Scholarships tabulated in another column three Evans Prizes of £3 3*s*., £2 2*s*., and £1 1*s* are given on the results of the class examination in midwifery, and two Durham Prizes, value £5 and £3, are given on the results of the class examination in gynæcology, and a prize of £5 is awarded in alternate years on the results of the class examination in Midwifery and Gynæcology respectively. The Evans Prize for Operative Midwifery, value £5 5*s*., is awarded yearly. Prizes of £10 each are awarded yearly in Anatomy and Physiology. There is also a small fund from which assistance can occasionally be given to students and to graduates who specially require pecuniary help. Honoraria from the Royce Memorial Fund are given to the assistant anæsthetists at the Royal Free Hospital. Prizes and Certificates of Honour are awarded in each class at the end of the session.

Special classes for the Preliminary Scientific examination of the University of London are held. The teaching in these classes has been greatly extended. The fee for the whole course is 20 guineas. Special courses of instruction in Anatomy, Physiology, and Chemistry are provided for students preparing for the Intermediate M.B. Examination of the University of London. The rebuilding of the School is now completed and the new buildings afford every facility for efficiency of teaching and of practical work in all departments.

Staff.—Physicians: Dr. S. West and Dr. Harrington Sainsbury. Assistant Physicians: Dr. J. W. Carr, Dr. R. H. P. Crawfurd, and Dr. A. G. Phear. Consulting Surgeons: Mr. A. Marsden, Mr. T. H. Wakley, Mr. W. Rose, and Mr. F. J. Gant. Surgeons: Mr. A. B. Barrow, Mr. J. Berry, and Mr. E. W. Roughton. Assistant Surgeons: Mr. W. H. Evans and Mr. T. Percy Legg. Physician for Diseases of Women: Dr. T. C. Hayes. Ophthalmic Surgeon: Mr. H. Work Dodd. Surgeon for Diseases of Throat, Nose, and Ear: Mr. E. W. Roughton. Surgeon for Diseases of Skin: Mr. W. H. Evans. Senior Resident Medical Officer: Mr. Joseph Cuming. Registrars: Miss Dobbie, M.D., and Miss Chadburn, M.B. Dentist: Mr. F. Todd. Anæsthetist: Miss Aldrich-Blake, M.D. Secretary: Mr. C. W. Thies.

Lecturers.—At the school: Anatomy and Practical Anatomy: Mr. Stanley Boyd Physiology and Practical Physiology: Dr. Brodie. Chemistry: Miss C. de B. Evans. Practical Chemistry: Miss Lucy Boole. Physics: Miss E. Stoney. Biology: Mr. Mudge. Materia Medica: Dr. H. Sainsbury. Practice of Medicine: Miss Cock, M.D., and Dr. J. W. Carr. Midwifery: *Mrs. Scharlieb, M.D.* Gynæcology: Mrs. Stanley Boyd. Forensic Medicine and Hygiene: Mrs. Dowson. Practice of Surgery: Mr. Berry. Operative Surgery: Mr. S Boyd. Ophthalmic Surgery: Miss Ellaby. Pathology: Dr. F. W. Andrewes. Mental Pathology: Dr. Mercier. Tropical Diseases: Dr. P. Manson. Operative Midwifery: Miss McCall, M.D. Demonstrator of Practical Toxicology, Mr. Bodmer; of Practical Gynæcology, Miss H. Webb, M.B.; of Anatomy, Miss Stoney, M.D., and Miss Flint, M.B.; of Chemistry, Miss Widdows; of Physiology, *Miss Vernon and Miss Cullis; of Practical Pharmacology,* Mrs. Clarke Kerr. At the Royal Free Hospital: Clinical Medicine: Dr. S. West and Dr. Sainsbury. Clinical Surgery: Mr. Barrow and Mr. Berry. Pathology: Dr. Crawfurd. Surgical Tutors: Mr. Roughton, and Mr. W. Evans. Medical Tutor and Demonstrator of Auscultation: Dr. J. W. Carr. Demonstrator of Practical Clinical Medicine: Miss Vaughan, M.D. Bacteriology: Mr. Roughton.

The Dean of the School is Mrs. Garrett Anderson, M.D.,; the Vice-Dean is Miss Cock, M.D.; the Honorary Secretary is Mrs. Thorne; and the Secretary is Miss Douie, M.B.

METROPOLITAN ANCILLARY SCHOOLS AND HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

Bethlem Royal Hospital.—This hospital is open for the admission of two Resident House Physicians who have recently obtained their diplomas to practise Medicine and Surgery. They will be permitted to reside in the hospital for a term generally not exceeding six months, commencing June 1st and 1st Dec., and will be provided with apartments, complete board, attendance, washing, and an honorarium of 25 guineas per quarter. They will be under the direction of the Resident Physician, and will be elected by the Committee from candidates whose testimonials appear to be most satisfactory. The students of certain specified London Medical Schools receive Clinical Instruction in the wards of the hospital, and qualified practitioners may attend for a period of three months on payment of a fee. Lectures are also given in connexion with the London Post-graduate Course.

Hospital for Consumption and Diseases of the Chest, Brompton (320 beds).—Four House Physicians reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms, £1 1*s*. for one month; three months, £2 2*s*.; perpetual, £5 5*s*. Lectures and Clinical Demonstrations are given throughout the year by members of the medical staff. The next course will *commence in October. Clinical Assistants* are appointed to the Assistant Physician in the out-patient department and Clinical Clerks to the Physician in the wards. The hospital has been recognised by the Conjoint Board for England as a place where six months of the fifth year may be spent in clinical work. The medical practice of the hospital is also recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital contains 321 beds in the two buildings.

Staff.—Consulting Physicians: Dr. E Pollock, Dr. E. S. Thompson, Sir R. D. Powell, Bart., Dr. F. T. Roberts, Dr. J. Tatham, Dr. C. T. Williams, and Dr. J. M. Bruce. Physicians: Dr. T. H. Green, Dr. J. K. Fowler, Dr. P. Kidd, Dr. T. D. Acland, Dr. R. Maguire, and Dr. H. W. G. Mackenzie. Assistant Physicians: Dr. S H. Habershon, Dr. G. Schorstein, Dr. F. J. Wethered, Dr. P. Horton-Smith, Dr. J. J. Perkins, and Dr A Latham Consulting Surgeons: Lord Lister, and Mr. R. J Godlee. Surgeon: Mr. S. Boyd. Dental Surgeon: Mr. W. Rushton. Resident Medical Officer: H. G. Felkin, M D.

City of London Hospital for Diseases of the Chest, Victoria Park.—During the past year 1021 in-patients have been treated in the wards, and the large number of 32,810 cases since the opening of the wards in 1855. The number of out-patients treated during 1899 was 15,260, and 614,207 since the commencement of the institution in 1848. Information as to medical instruction can be obtained on application to Dr. E. Clifford Beale, the Secretary of the Clinical Sub-committee at the hospital.

Staff.—Consulting Physicians: Dr. E. L. Birkett, Dr. J. C. Thorowgood, and Dr. Eustace Smith. Consulting Surgeon: Lord Lister. Physicians: Drs. G. A. Heron, Vincent D. Harris, E. Clifford Beale, Harrington Sainsbury, T Glover Lyon, and Sir Hugh Beevor, Bart. Surgeon: Mr. J. F. C. H. Macready, F.R.C.S. Physicians to Out-Patients: Sir Hugh R. Beevor, Bart., and Drs. W. J. Hadley, E. H. Colbeck, Arnold Chaplin, Hugh Walsham, Wilfred J. Harris, and Oliver K. Williamson. Secretary: Henry T. Dudley Ryder. Secretary of the Medical Committee: Dr. Hugh Walsham.

Central London Throat and Ear Hospital, Gray's Inn-road.—The hospital contains accommodation for 17 in-patients, and has a very extensive out-patient

---

Sub-Dean.

department, which is open to all medical practitioners and students for the purpose of clinical demonstration and instruction during the hours of the surgeons' visits. During the past year 8428 out-patients (involving 53,041 attendances) and 240 in-patients were treated. Fee for three months' attendance, 3 guineas; for six months, 5 guineas. A course of lectures on the special diseases treated at this hospital is delivered during the winter months by members of the staff. The date of these lectures is announced in the medical journals prior to their commencement. They are free to qualified practitioners and advanced students of medicine. Considerable attention is given to scientific work, particularly with regard to Bacteriology of the ear and respiratory passages. Operation days: in-patients, Tuesday, at 2 P.M.; out-patients, Tuesday, at 3 30 P.M., and Friday, at 2 P.M. Consulting Surgeons: Mr. Thomas Nunn and Mr. Lennox Browne. Surgeons: Dr. Arthur Orwin, Dr. Dundas Grant, and Dr. Percy Jakins. Physician and Pathologist: Dr. Wyatt Wingrave. Assistant Surgeons: Dr. Holloway, Mr. Nourse, and Dr. Abercrombie. Bacteriologist: Mr. St George Reid. Dental Surgeon: Mr. George Wallis. Anæsthetist: Mr. W. Hotten George. Defects of Speech: Mr. William Van Praagh. In addition the following appointments are open to qualified members of the profession:—Assistant Registrar, tenable for twelve months; and twelve Clinical Assistants, tenable for six months. Secretary: Mr Richard Kershaw.

THE HOSPITAL FOR WOMEN, Soho-square, W.—In connexion with this institution there has been for some years a well-organised Clinical Department, which has been enlarged under the title of the London School of Gynæcology. To meet the want increasingly felt by medical men of an accurate knowledge of the ordinary diseases of women, gentlemen are appointed to act as clinical assistants to the physicians and surgeons seeing out- and in-door patients. The appointments are nominally "open to qualified medical men and to students of medicine after their fourth year," but in the selection of candidates preference is naturally given to gentlemen already engaged in practice. The large number of out-patients affords exceptional opportunities for practical instruction in the use of gynæcological instruments and for the study of diseases peculiar to women. Demonstrations are given in the theatre on Mondays and Thursdays at 2 P.M. Fee for one month £3 3*s*.; for the three months' course and certificate £8 8*s*. Any further information can be obtained by writing to the Dean at the hospital.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road. (80 beds)—This hospital has been enlarged by the addition of a very complete out-patients' department, and also by the erection of a new wing, which provides accommodation for 80 in-patients. Expenditure for 1900, £7702; income (including legacies, £669), £7365. The attendance of out-patients averages 26,000 annually.

Staff.—Consulting Physicians: Dr. Horace Dobell and Professor D W. Finlay. Physicians: Dr. P. J. Hensley, Dr. T. G. Smith, Dr W. H. White, Dr. Oswald Browne, Dr. A. Davies, and Dr. J. Calvert. Assistant Physicians: Dr. B. Dawson, Dr. M Leslie, and Dr. J. H. Drysdale Consulting Surgeon: Mr. J. Hutchinson. Surgeon: Mr W. Turner. Resident Medical Officer: Dr. E. Talbot House Physician: Mr. H. B. Gibbins. Secretary: Mr. J. Harrold.

ROYAL EAR HOSPITAL, Soho. (Founded 1816.)—Courses of instruction of six weeks' duration in Diseases of the Ear and Nose are given by the members of the staff throughout the year. Students can attend one or more surgeons, the fee for each surgeon's course being one guinea. The teaching is of a practical character, and the number of students is limited. The next series of classes will commence on Oct. 1st. For information address the Honorary Secretary of the Medical Board.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—Consulting Physician: Sir S. Wilks, Bart. Physicians: Drs. R. Burnet, E. C. Beale, C. E. Beevor, H. W. Syers, A. Morison, and T. J. Horder. Obstetric Physician: Dr. Blacker. Surgeons: Messrs. J. Macready, H. Allingham, P. T B. Beale, G. B. M. White, and E. C. Stabb. Ophthalmic Surgeon: Mr. A. S. Morton. Ear, Throat, and Nose Surgeons: Mr W. R. H. Stewart and Mr. E. B. Waggett Skin Department: Dr. Whitfield. Dental Surgeon: Mr. C. F. P. Baly. This hospital is now recognised by the Examining Board in England of the Royal Colleges of Physicians and Surgeons as a place of study during the fifth year of the Medical Curriculum. The hospital contains 159 beds, which are now all occupied. The large rectangular and circular wards, each of which contains 20 beds, the operation theatre, out-patient, general and special, and the pathological departments, have all been erected since 1887. They are specially designed with a view of offering the greatest facilities for clinical work, and contain all the most recent and approved hygienic and antiseptic requirements for the proper care of the sick and for the treatment of disease. Medical practitioners are cordially invited to see the general and special practice of the hospital. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office. Further particulars from Peyton T. B. Beale, F.R.C.S., Honorary Secretary Medical Committee, 61, Grosvenor-street, W.

NEW HOSPITAL FOR WOMEN, 144, Euston-road, N.W.—Physicians for In-patients: Miss Cock, M.D., and Miss Walker, M.D. Surgeons for In-patients: Mrs. Scharlieb, M.D., M.S., and Mrs. Boyd, M.D. Physicians and Surgeons for Out-patients: Miss Webb, M.B., Miss Macdonald, M.B., and Miss Aldrich Blake, M.D., M.S. Children's Department: Mrs. Flemming, M.D. Ophthalmic Surgeon: Miss Ellaby, M.D. Assistant Physicians for Out-patients: Miss Vaughan, M.D., Miss Sturge, M.B., and Miss Thorne, M.D. Physician for Maternity Department: Miss Clapham, M.B. Anæsthetist: Mrs. Keith, L.R.C.P. A considerable number of the students hold posts in the New Hospital under the visiting staff, and in return for much valued clinic teaching they do the work assigned to students in th wards of a general hospital. Secretary: Miss M. Bagster.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W (Established 1873.)—Physicians: Dr. Fenwick, Dr. Parkinso and Dr. Addinsell. Surgeons: Dr. W. J. Collins, F.R.C S and Mr. H. J. Paterson, F.R.C.S. Dental Surgeon: Mr. Alexander. The hospital contains 110 beds. The in-patien in 1900 were 1282, and the out-patients and casualti numbered 22,339 new cases. The medical and surgic practice of the hospital is open to students and pract tioners. Special departments for Ophthalmology an Gynæcology. Operations: Mondays and Thursdays, 3.30 P. Classes will be held during the winter and summer sessio for students preparing for the final examinations at th Colleges and the Universities. Appointments, vacancies f which are advertised in the medical journals: Medical an Surgical Registrars and Pathologist; Resident Medical Office and Assistant Resident Medical Officer. For particula as to hospital practice and classes apply at the hospital t Dr. W. J. Collins.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPT (Albany Memorial), Queen-square, Bloomsbury.—The hos pital, with the Finchley branch, contains 200 beds and cot The physicians attend every Monday, Tuesday, Wednesda and Friday at 2 P M. In- and out-patient practice an electrical-room treatment at that hour. Physicians: Drs Hughlings Jackson, Buzzard, Bastian, Sir William Gower D. Ferrier, Ormerod (physicians for out-patients), Beevor Tooth, James Taylor, and J. S. Risien Russell. Assistan Physicians: Drs. Aldren Turner and Batten. Surgeons Messrs. Victor Horsley and C. A. Ballance. Ophthalmi Surgeon: Mr. Marcus Gunn. Aural Surgeon: Mr. A. E Cumberbatch. Laryngologist: Sir Felix Semon. Anæsthetist: Dr. R. T. Bakewell. Pathologist: Dr. Collier Registrar: Dr. F. Buzzard. House Physicians: Dr. Singe and Dr. Barnes. The hospital has been recognised b the Conjoint Board for England as a place where part o the fifth year may be devoted to clinical work All communications concerning clinical appointments, lectures and hospital practice should be addressed to the Secretar and Director at the hospital.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL AND MIDWIFERY TRAINING SCHOOL, Marylebone-road, N.W.—Consulting Physician: Dr. George B. Brodie. Consulting Surgeon: Sir William Mac Cormac. Physicians to In-patients: Dr. W. S. A. Griffith, Dr. W. Rivers Pollock, and Dr. W. J. Gow. Physicians to Out-patients: Dr. T. W. Eden, Dr. C. Hubert Roberts, and Dr. Arthur F. Stabb. This hospital, which has been recently again enlarged and in which many important improvements have been carried out, receives 1200 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases — nearly three-fourths of the total admissions. Clinical instruction is given on the more important cases which present themselves. Certificates of attendance at this hospital are recognised by all Universities, Colleges, and licensing bodies. Pupil midwives and monthly nurses are received and specially trained. Fees: Medical Students, £8 8s. for four weeks; Qualified Medical Practitioners £8 8s. for four weeks. Pupil Midwives, £26 5s for three months (including board and lodging); Pupil Nurses, £15 15s. for twelve weeks (including board and lodging). The new residence for students and qualified practitioners is opposite the hospital, with which it is in telephonic communication. Terms for residence and full board 35s. per week. For further particulars application should be made to Mr. Arthur Watts, Secretary, at the hospital.

THE SEAMEN'S HOSPITAL SOCIETY.—There are two hospitals—the *Dreadnought* Hospital at Greenwich (225 beds) and the Branch Hospital in the Royal Victoria and Albert Docks, E. (50 beds). There are also two Dispensaries, one in the East India Dock-road and the other at Gravesend, which supply patients to the hospitals. The London School of Tropical Medicine, with its laboratories, museum, library, &c, is within the grounds of the Branch Hospital. Honorary medical staff of the hospitals:—Consulting Physician: Dr. Robert Barnes. Consulting Surgeon: Mr. W. Fowler. Physicians: Dr. P. Manson, C M.G., F.R S., Dr. R. Tanner Hewlett, Dr. Guthrie Rankin, Dr. Andrew Duncan. Physician to Out-patients: Dr. Oswald Baker. Surgeons: Mr. W. Johnson Smith, Mr. William Turner, Mr. James Cantlie. Surgeon to Out-patients: Mr. J. Brian Christopherson. Ophthalmic Surgeon: Mr. L. Vernon Cargill. Dental Surgeons: Mr. Kenneth W. Goadby and Mr. J. Warburton Brown. The lecturers in the school are Dr. P. Manson, C M.G., F.R.S., Dr. Andrew Duncan, Dr. Oswald Baker. Dr. L. Westenra Sambon, Dr. J. Galloway, Dr. R. Tanner Hewlett, Mr James Cantlie, Mr. E. Treacher Collins, and Dr. W. J. Simpson. Appointments.—There is a House Physician and a House Surgeon at the *Dreadnought* Hospital, Greenwich, a Senior House Surgeon and House Surgeon at the Branch Hospital, and a Surgeon at each of the Dispensaries. The pay of these officers varies from £50 to £100. Scholarships — The Craggs Research Scholarship of £300 per annum was awarded last year to Mr. G. C. Low. Opportunities are afforded to Medical Graduates who may be desirous of studying Diseases Incidental to Tropical Climates and also Practical Surgery before entering the services or going abroad. In the hospitals of the Society are to be found cases of tropical disease such as may be met with in actual practice in the tropics. There are three courses in the year, each lasting three months, the first beginning Oct 1st. Certificates are granted after examination to those who complete a full course. Resident chambers are available for students who must be post graduates or in the fifth year of their medical studies. The School is under the auspices of His Majesty's Government. Over 140 students have passed through the school since its opening in October, 1899. A free register is maintained at the School, giving the names of gentlemen qualified to take duty as medical officers in the tropics. For terms apply to the Secretary, Mr. P. Michelli, Seamen's Hospital, Greenwich, S.E

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C., contains 200 beds, divided into 102 medical, 73 surgical, and 25 for special and infectious cases, besides 52 beds at the convalescent branch, Highgate. The hospital having been recognised by the Conjoint Board for England as a place where, under the new curriculum, six months of the fifth year may be spent in clinical work, the practice is arranged to meet this need and is open to students who have completed four years of medical study and also to qualified medical men. Appointments are made every three months to six medical clerkships and six surgical clerkships, which are open to students of the hospital. Lectures or demonstrations are given once or twice every week during both winter and summer sessions, which qualified practitioners are invited to attend free of charge. The sessions are of ten weeks' duration, and begin in October, January, and March. Fees for hospital practice, three months, 2 guineas; perpetual, 3 guineas. Prospectuses and further information will be forwarded on application to the Secretary, Mr. Adrian Hope, at the hospital.

Staff.—Consulting Physicians: Dr. J W. H. Dickinson, Dr. W. B Cheadle, and Sir Thomas Barlow. Physicians: Dr. David B Lees, Dr. Francis G. Penrose, Dr. A. E Garrod, and Dr. A. F. Voelcker. Assistant Physicians: Dr. W. S Colman, Dr. F. E Batten, Dr. G F. Still, Dr. F. J. Poynton, and Dr. Robert Hutchinson. Consulting Surgeons: Sir Thomas Smith, Bart, Mr. Howard Marsh, Mr. Edmund Owen, and Mr. John Morgan. Surgeons: Mr. Bernard Pitts, Mr. W. Arbuthnot Lane, and Mr Charles A. Ballance. Assistant Surgeons: Mr. Thomas H Kellock, Mr. H. Stansfield Collier, and Mr. Francis J. Steward. Ophthalmic Surgeon: Mr. W. T. Lister. Aural Surgeon: Mr. Thomas H Kellock. Surgeon-Dentist: Mr. Alexander Cartwright Local Medical Officer for Cromwell House: Dr. A. M. Anderson. Medical Registrar and Pathologist: Dr Hugh Thursfield. Surgical Registrar: Dr. Lewis Wallace Anæsthetist: Dr R. T. Bakewell. Resident Medical Superintendent; Dr. H. A. T. Fairbank. Secretary: Mr. Adrian Hope. Assistant Secretary: Mr. James McKay.

ROYAL LONDON OPHTHALMIC HOSPITAL (Moorfields, 1804-1899), City-road, E C.—138 beds. This hospital, known as Moorfields Eye Hospital, was moved in 1899 to new and larger buildings in City-road. In 1900 there were 1841 in-patients, the out-patients were 36,932, and the attendances were 99,821. Operations are performed daily from 10 A M. to 1 P M., and four surgeons attend on each day. Students are admitted to the practice of the Hospital. Fee for six months, £3 3s.; perpetual, £5 5s. Courses of instruction on the following subjects are given at the Hospital periodically: (1) the use of the ophthalmoscope; (2) errors of refraction; (3) external diseases of the eye; and (4) surgical anatomy of the eye. Systematic instruction is also given in the laboratory of the hospital on the pathology of the eye. Perpetual students are admitted to the lectures free Students of the hospital are eligible for the offices of house surgeon or clinical and junior assistants Junior assistants are appointed every three months. Any further information will be furnished by Mr. Robert J Bland, Secretary.

Staff.—Physicians: Dr. S Mackenzie and Dr. J. Taylor. Consulting Surgeons: Mr J Hutchinson, Mr. G Lawson, Mr. J Couper, and Mr. E Nettleship Surgeons: Mr. W. Tay: Mr. J Tweedy, Mr. R M. Gunn, Mr. W. Lang, Mr. A. Q. Silcock, Mr. J. B. Lawford, and Mr. A S. Morton. Assistant Surgeons: Mr. E T. Collins and Mr. W. T. H. Spicer House Surgeons: Mr. D N. Maclennan and Mr. W. E. Smith Curator and Registrar: Mr. C D. Marshall.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand —The hospital contains 36 beds Patients, who number 11,000 annually, are seen at 1 P.M., and operations performed daily at 2 P M. The following are the days of attendance of the surgeons: Mr. Hartridge and Mr. Grimsdale, Mondays and Thursdays; Mr Frost and Mr Roll, Tuesdays and Fridays; and Mr. Dodd and Mr. Griffith, Wednesdays and Saturdays. The practice of the hospital is open to practitioners and students Fees for six months, £3 3s.; perpetual, £5 5s. Consulting Physicians: Sir Wm. Broadbent, Bart., Sir Francis Laking, and Dr. Ridge Jones. Consulting Surgeons: Mr. Cowell and Mr. Pickering Pick. Physicians: Drs. Montague Murray, Walter Carr, Humphry D. Rolleston, William Cecil Bosanquet, F. Whittaker Tunnicliffe, and William James Fenton. Surgeons: Messrs. D'Arcy Power and Raymond Johnson. Surgeons to the Out-patients: Messrs. H. F. Waterhouse and Rupert H. Bucknall. Ophthalmic Surgeon: Mr. C. Devereux Marshall. Dental Surgeon: Mr. O. E. Wallis. Anæsthetists: Dr. Paul Frank Moline, Dr. C. J. Harrison, and Dr. Corbould. House Surgeon: Mr. D. D. Turner. House Physicians: Drs. A. E. Craven and G. O. Lambert. Secretary: Mr. H. G. Evered. Out-patients are seen as under:—Medical and Surgical Cases: Mondays and Thursdays, 9.30 A.M. and 1.30 P.M.; Thursdays and Fridays, 1.30 P.M.; Wednesdays, 9.30 A.M. Dental Cases: Saturdays, at 9 A.M

WEST LONDON HOSPITAL, Hammersmith-road, W.—This hospital has 160 beds, all of which are at present in use About 2050 in-patients and 32,000 out-patients, whose attendances number 75,000, are treated annually. Physicians: Drs D. W. C. Hood, F. G. D. Drewitt, and Seymour Taylor Physician for Diseases of Women: Dr. J. A. Mansell Moullin Surgeons: Messrs. C. B. Keetley, F. Swinford Edwards, and S. Paget. Surgeon (with charge of out-patients): Mr. L. A Bidwell. Surgeon for Diseases of the Eye: Mr. H. P Dunn. Assistant Physicians: Drs. A. P. Beddard, E. A. Saunders, and H. Davis. Assistant Physician for Diseases of Women: Dr. G. H. Drummond Robinson. Assistant Surgeons: W. McAdam Eccles and Mr. A. Baldwin. Surgeon-Dentist: Mr. H. Lloyd Williams. Physician-in-Charge of Throat and Nose and Aural Department: Dr. J. B. Ball Surgeon-in-Charge of Orthopædic Department: Mr. C. B. Keetley. Pathologist: Mr. E. A. Saunders. Dermatologist: Dr. P. S. Abraham. Administrators of Anæsthetics: Messrs. T. Gunton Alderton and Rickard W. Lloyd. Assistant Administrator of Anæsthetics: Messrs E. W. Lewis and G. P. Shuter. Electrician: Dr. H. Davis. Secretary: Mr. R. J. Gilbert. Attached to the hospital is the West London Post-graduate College. The practice of the Hospital is reserved exclusively for qualified men, no junior students being admitted. Instruction is given in the medical and surgical out-patient rooms daily, and demonstrations are given in the wards on certain fixed days. Post-graduate lectures and demonstrations are given daily except Saturdays; notice of the commencement of each course is advertised in the medical journals. Special Classes are held in Diseases of the Throat and Nose, Skin, Ear, and in Anæsthetics. The accommodation for post-graduates consists of a large lecture room together with reading and writing rooms, &c. The hospital has a fully-equipped pathological laboratory at which instruction can be given in elementary bacteriology. The fees for hospital practice, including lectures, are £3 3*s*. for 3 months or £7 7*s*. for one year. The certificate of the hospital is accepted by the Admiralty and War Office in cases of study leave. Further information can be obtained on application to the Dean Mr. L. A. Bidwell, at the hospital.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Bethnal-green, N.E. For the sick children of the poor under 12 years of age. Established 1867. City Offices: 27, Clement's-lane, E.C—57 beds. During the past year 778 in-patients and 18,264 out-patients (representing 62 931 attendances) were relieved, 232 of the in-patients being under two years of age. Consulting Physicians: Drs. A. E. Sansom, W. Cayley, F. C. Turner, and W. Pasteur. Consulting Surgeons: Messrs. Jonathan Hutchinson, Waren Tay, R. J. Godlee, Bilton Pollard, and H. Percy Dean. Physicians: Drs. W. A. Wills, James Taylor, J. H. Sequeira, and J. Porter Parkinson. Surgeons: Messrs. A. B. Roxburgh and Douglas Drew. Ophthalmic Surgeon: Mr. Sydney Stephenson (Wednesday, 9.30 A.M.). Dental Surgeon: Mr. John W. Pare (Tuesday, 9.30 A.M., and Friday, 2.30 P.M.). Matron: Miss E. W. Curno. Secretary: Mr. T.

Glenton-Kerr. The surgeons attend on Wednesdays and Saturdays at 2 P.M.; the physicians daily at 2 P.M. Applications for permission to attend the practice of the hospital should be addressed to the secretary.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Consulting Physician: Dr. Donald W. C. Hood. Physician: Dr. Harry Campbell. Surgeon: Mr. Frederic Durham. Assistant Physicians: Drs. W. Knowsley Sibley, G. A. Sutherland, and [vacant]. Assistant Surgeons: Messrs. M. P. Mayo Collier, J. Jackson Clarke, and George Templeton. Physician for Diseases of the Skin: Dr. J. Herbert Stowers. Obstetric Physician: Dr. John Shaw. Ophthalmic Surgeon: Dr. W. J. Collins. Dental Surgeon: Mr. G. Russell. The hospital, which was established in 1878, provides 53 beds. The average number occupied last year was 48. It is a general hospital. There are two spacious wards for men and women respectively. The children's wards contain 18 cots. There are two Resident Medical Officers—an honorarium at the rate of £50 per annum attaches to each post. Operation day, Thursday at 2 30 o'clock. Further particulars from the secretary at the hospital.

PROVINCIAL MEDICAL SCHOOLS AND HOSPITALS HAVING SPECIAL CLASSES AND FACILITIES FOR CLINICAL STUDY.[1]

THE UNIVERSITY OF BIRMINGHAM (FACULTY OF MEDICINE).—An Ingleby Scholarship is annually awarded to the candidate obtaining highest marks in Obstetric Medicine and Surgery and *Diseases* of Women and Children at the final M.B. examination. One or more Sydenham Scholarships are offered annually of the value of 40 guineas each. The orphan sons of former students of the Birmingham Medical School have priority of election. No Sydenham scholars are elected whose age exceeds 23 years on the day of election. The Scholarships are held for three years, subject to good behaviour. A Sands Cox Scholarship is offered annually of the value of 40 guineas. It may be held for three years, one-third being paid each year, subject to good behaviour. Queen's Scholarships of the value of £10 10*s.* are awarded at the end of the University examinations. The Russell Memorial Prize is awarded annually after examination in Nervous Diseases. There are Faculties of Arts, Science, and Medicine. The medical courses qualify for the diplomas of all Licensing Bodies and for the degrees in Medicine and Surgery of British Universities The Dental School, in conjunction with the General, Queen's, and Dental Hospitals, affords a complete curriculum for all Dental diplomas. The Library contains upwards of 25 000 volumes. Syllabuses containing full information as to the various courses of instruction, lecture days and hours, fees, scholarships, &c., will be forwarded on application to the Dean of the Medical Faculty. The Medical Session opens on Oct. 1st. There are no changes in the staff.

THE GENERAL AND QUEEN'S HOSPITALS, BIRMINGHAM.—The practices of these hospitals are amalgamated for the purpose of Clinical Instruction under the direction of the Birmingham Clinical Board by whom all schedules will be signed and all examinations conducted. The hospitals have a total of upwards of 450 beds. 7000 in-patients and 90 000 out-patients are treated annually. The following appointments are open to past students. At the General Hospital: two resident medical officers, salary £70 a year (a degree in medicine is necessary); one resident surgical officer, salary £100 a year; one resident pathologist, salary £100 a year; two non-resident casualty assistant physicians, salary £50 a year; two non-resident surgical casualty officers, salary £50 a year; two non-resident anæsthetists, salary £50 a year; four house surgeons, office tenable for six months without salary; two assistant house physicians, tenable for six months without salary; one resident medical officer at the Jaffray Branch Hospital salary £150 a year; and one resident assistant at the Jaffray Hospital (post vacant early in April, July, October, and January, tenable for three months) At the Queen's Hospital in connexion with the Birmingham University: three qualified house physicians (posts vacant in March, September, and December, tenable for 12 months at a salary of £50); three qualified house surgeons (posts vacant in March, September, and December, tenable for 12 *months at a salary of £50); one qualified obstetric* and ophthalmic house surgeon (post vacant in March and September, tenable for six months), salary £20; and one unqualified resident dresser (post vacant on the first day of January, April, July, and October, tenable for three months).

Staff of General Hospital: Consulting Physicians: Sir W. Foster and Sir W. Wade. Physician: Dr. E. Rickards, Dr. R. Saundby, Dr. R. M. Simon, and Dr. S. Wilson. Surgeons: Mr T. F. Chavasse, Mr. G. Barling, Mr. W. F. Haslam, and Mr. G. Heaton. Obstetric Physician: Dr. E. Malins. Ophthalmic Surgeon: Mr. D. C. Lloyd-Owen. Assistant Physicians: Dr. T. S. Short and Dr. J. W. Russell. Assistant Surgeons: Mr. A. Lucas and Mr. L. P. Gamgee. Assistant Obstetric Physician: Dr. T. Wilson. Anæsthetists: Dr. S. Haynes and Dr. W. J. McCardie. Casualty Assistant Physicians: Dr. J R. Charles and Dr. S. H. Perry. Surgical Casualty Officers: Mr. A. D. Heath and Mr. A. P. Satchell. Dental Surgeon: Mr. D. Whittles. Surgical Radiographer: Dr. F. Hall Edwards.

Staff of Queen's Hospital.—Consulting Physicians: Sir J. Sawyer and Dr. Suckling. Consulting Surgeons: Mr. F. Jordan and Mr J. St. S. Wilders. Physicians: Dr. Carter, Dr. Foxwell, and Dr. Kauffmann. Surgeons: Mr. B. May, Mr. J. Lloyd, and Mr. F. Marsh. Ophthalmic Surgeon: Mr. Priestley Smith. Obstetric Officer: Dr. Purslow. Physician for Out-patients and Pathologist: Dr. Stanley. Casualty Surgeons: Mr. J. T. J. Morrison, Mr. J. H. Clayton, and Mr. C. A. L. Green. Assistant Ophthalmic Surgeon: Mr. Wilfred Allport.

UNIVERSITY COLLEGE, BRISTOL (FACULTY OF MEDICINE).—It is now arranged that Students of the College shall be admitted to the Clinical Practice of the Bristol Royal Infirmary and the *Bristol General Hospital conjointly* and consequently both these institutions are open to all Students. The Infirmary and the Hospital comprise between them a total of 470 beds; and both have very extensive out-patient departments, special departments for the Diseases of Women and *Children*, and of the *Eye*, Ear, and Throat, besides large outdoor Maternity Departments and Dental Departments. Students may also attend the practice of the Bristol Royal Hospital for Sick Children and Women, containing 104 beds, and that of the Bristol Eye Hospital, with 28 beds. The total number of beds available for clinical instruction is 602. Very exceptional facilities are thus offered to Students for obtaining a wide and thorough acquaintance with all branches of Medical and Surgical work. Each Student has the opportunity of personally studying a large number of cases and of acquiring practical skill in diagnosis and treatment.

Courses of Lectures.—Medicine: Professors E. Markham Skerritt, M.D. Lond, B S, B A, F.R.C P., and J. E. Shaw, M B, C.M. Surgery: Professors C A Morton, F.R.C S., and James Swain, M D., M S. Lond., F R.C S. Anatomy: Professor Edward Fawcett, M B. C.M. Edin. Practical Anatomy: Demonstrators, Dr. J. O. Symes and Mr. T. Carwardine. Physiology and Histology: Professor A. F. Stanley Kent, M.A., F.L S., F.G.S. Chemistry: Lecturer, Professor Sydney Young, D Sc., F.R S. Public Health: Lecturer, Dr. D. S. Davies. Midwifery and Diseases of Women: (Vacant). Medical Jurisprudence: Lecturers, Dr. R. Eager and Dr. G. Parker. Pathology and Morbid Anatomy: Professor J. Michell Clarke. Operative Surgery: Lecturer, Mr. J. Paul Bush. Practical Medicine: Lecturer, Dr. J. E. Shaw. Practical Surgery: Lecturer, Dr. R. G. Poole Lansdown. Practical Midwifery: Lecturer, Dr. W. C. Swayne. Materia Medica and Practical Pharmacy and Pharmacology and Therapeutics: Lecturer, *Dr. A. B. Prowse.* Biology: Lecturer Professor S H. Reynolds. Practical Chemistry: Lecturer, Professor Sydney Young. Practical Bacteriology: Lecturer, Professor A F. Stanley Kent, M.A., F.L.S., F.G S. Comparative Anatomy: Lecturer, Professor C. Lloyd Morgan, F.R.S. Dental Anatomy and Physiology: Lecturer, Professor A. F. Stanley Kent, M.A. F.L.S., F.G S. Dental Surgery: Lecturer, Mr. W. R. Ackland. Dental Mechanics and Dental Metallurgy: Lecturer, Dr. C. A. Hayman. Composition fee for lectures, 65 guineas or 55 guineas. Composi*tion fee for Dental Lectures, 55 guineas.* Special six months' course for Diploma in Public Health. 1. Lectures on Public Health: Dr. D. S. Davies. 2. Bacteriology: Professor A. F. Stanley Kent, M.A., F.L.S., F.G.S. 3. Laboratory Course of Hygienic Chemistry: Mr. F. W. Stoddart. 4. Demonstrations on the Various Acts, Orders, By-laws, &c.: Mr. J. C. Heaven. 5. Practical Outdoor Sanitary Work: Dr. D. S. Davies. Fee for the entire course 30 guineas.

---

[1] For Scholarships see page 693 et seq.

ROYAL INFIRMARY, BRISTOL (Established 1735).—270 beds. Honorary and Consulting Physicians: Dr E. Long Fox and Dr. W. H. Spencer. Honorary and Consulting Surgeon: Mr. E. C. Board Honorary and Consulting Ophthalmic Surgeon: Mr. F. Richardson Cross Physicians: Dr. R. Shingleton Smith, Dr. Henry Waldo, Dr. J. E Shaw, and Dr. Arthur B. Prowse. Surgeons: Mr. A. W. Prichard, Mr. W. H. Harsant Mr. J. Paul Bush, and Mr. G. Munro Smith. Ophthalmic Surgeon: Dr. Ogilvy. Obstetric Physician: Dr. Walter C. Swayne Dental Surgeon: Mr. W R. Ackland. Assistant Physicians: Dr. P Watson Williams and Dr. F. H. Edgeworth Assistant Surgeons: Dr. James Swain and Mr. T. Carwardine. Pathologist: Dr Theodore Fisher Bacteriologist: Professor A. F. Stanley Kent, M.A. Skiagraphist: Mr. James Taylor. House Surgeon: Mr. H. F. Mole. House Physician: Dr. E. H E. Stack. Resident Obstetric Officer: Mr F. A. Coates. Anæsthetist and Junior House Surgeon: Mr. E. C Mackay. Casualty Officer: Mr. H. E. G. Boyle.

BRISTOL GENERAL HOSPITAL —Honorary and Consulting Surgeons: Mr. Robert W. Cue, Dr George F. Atchley, Mr. Nelson C. Dobson, and Mr. F. Poole Lansdown. Honorary and Consulting Physician Accoucheurs: Drs. Joseph G. Swayne and A. E. Aust Lawrence. Physicians: Drs E. Markham Skerritt, Alfred J. Harrison, and J. Michell Clarke. Surgeons: Messrs. Charles F. Pickering, W. M. Barclay, and C. A. Morton and Dr. R. G. Poole Lansdown. Physician Accoucheur: Dr. W. H C. Newnham. Physician to the Throat and Nose: Dr. Barclay J. Baron Ophthalmic Surgeon: Mr. Cyril H. Walker. Assistant Physicians: Dr. George Parker and Dr. J. O. Symes. Assistant Surgeon: Dr J. Lacy Firth Assistant Physician Accoucheur: Mr. F. C. Rayner. Anæsthetist: Mr. J. Freeman. Dental Surgeon: Mr T. Taylor Genge. Pathologists: Dr. J. Michell Clarke and Dr. J. Lacy Firth. Bacteriologist: Dr. J. O. Symes. House Surgeon: Mr. H. P. Kyle. Assistant House Physician: Mr. A. F. Martin. Assistant House Surgeon: Mr. S. R. Williams. Casualty House Surgeon: Mr. J. W. Malim.

Clinical Scholarships and Prizes.—These are open for competition only to "Perpetual" Clinical Students. 1. Open Scholarships and Prizes:—(*a*) University Entrance Scholarship of £50 and Haberfield Entrance Scholarship of £27 10*s*. (*b*) Tibbitts Surgical Prize, £9 9*s*.; and two Martyn Pathological Prizes of £10 each. (*c*) A Gold Medal and a Silver Medal given by the Committees of the two institutions. 2. Restricted to students who have done the necessary qualifying work at the Bristol Royal Infirmary: Suple Medical Prize (consisting of a Gold Medal, value 5 guineas, and 7 guineas in money); Suple Surgical Prize (consisting of a Gold Medal, value 5 guineas, and 7 guineas in money); Clark Prize, value £11 11*s*.; Crosby Leonard Prize in Clinical Surgery, value £7 7*s*; and Augustin Prichard Prize in Surgical Anatomy, value £7 7*s*. 3. Restricted to students who have done the necessary qualifying work at the Bristol General Hospital:—Clarke Scholarship, a surgical scholarship of the value of £15; Sanders Scholarship a scholarship of the value of £22 10*s*.; and the Marshall Prize, value about £10.

Resident Appointments.—There are five resident appointments at the Infirmary and four in the Hospital, and the Dressers reside in rotation, free of expense. The Maternity students also have rooms provided in the institutions.

Fees.—Medical Practice: three months, 4 guineas; six months, 7 guineas; one year, 12 guineas; perpetual, 20 guineas. Surgical Practice: three months, 4 guineas; six months, 7 guineas; one year, 12 guineas; perpetual, 20 guineas. Medical and Surgical Practice together in one payment: six months, 12 guineas; one year, 20 guineas; perpetual, 35 guineas. Dental Surgical Practice: one year, 7 guineas; perpetual, 12 guineas. The above fees include Clinical Lectures. Clinical Clerkship: 5 guineas for six months. Dressership: 5 guineas for six months. Museum fee: 3 guineas (composition on entrance), or 1 guinea annually. Dispensing Fee: 2 guineas. Students from other schools or qualified medical men wishing to attend Clinical Practice for short periods and not requiring certificates for such attendance may do so for the following fees:—Medical and Surgical Practice conjointly: one month, 2 guineas; two months, 3 guineas; three months, 4 guineas; and six months, 7 guineas.

Further information may be obtained on application to the Dean of the Faculty.

OXFORD: RADCLIFFE INFIRMARY.—At this infirmary instruction is given in connexion with the Oxford University Medical School. Clinical lectures are given by the Lichfield Clinical Lecturers in Medicine and Surgery. Also tutorial instruction and demonstrations are given in special Regional Anatomy (medical and surgical), methods of Medical Diagnosis, and Surgical Manipulation. Demonstrations of Elementary Pathology are given in the post-mortem room and at the Pathological department of the museum by the Regius Professor of Medicine or his Deputy. Practical Pharmacy is taught in the Infirmary Dispensary. The whole course of study at the museum and infirmary combined is intended for students until they have passed the Second Conjoint Examination or the First Oxford M.B. The infirmary contains 146 beds.

CAMBRIDGE: ADDENBROOKE'S HOSPITAL.—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are delivered at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery in the wards and out-patients' rooms is given by the physicians and surgeons daily, during the vacations as well as term-time. Instruction is also given in the special methods of medical and surgical investigation. Clinical Clerks and Dressers are selected from students according to merit and without payment. The composition fee for pupilship is 8 guineas.

UNIVERSITY COLLEGE, CARDIFF, SCHOOL OF MEDICINE.—The winter session will commence on Monday, Oct. 7th. All classes are open to both men and women students who may spend three out of their five years of medical study at Cardiff. The courses of study are recognised as qualifying for the Preliminary Scientific and Intermediate Examination in Medicine in the University of London and for the corresponding examinations in the other Universities. Students who are preparing for these examinations may compound for their courses by paying a fee of £57 10*s*., while a composition fee of £40 includes all the necessary courses for the first and second examinations for the Diploma of the Conjoint Board. In all cases the composition fees may be paid by instalments. Hospital instruction is given at the Cardiff Infirmary. The attention of students about to matriculate is drawn to the numerous entrance scholarships and exhibitions, varying in value from £10 to £30 per annum, offered for competition at University College, Cardiff, in September next, most of which may be held by medical students. Full particulars of the examination for these may be obtained by application to the Registrar. In the department of Public Health recently established instruction is given qualifying for the D.P.H. examinations Further information may be obtained from Professor A. Francis Dixon, Dean of the Faculty of Medicine.

Lecturers.—Physics: Professor A. L. Selby. Chemistry: Professor C. M. Thompson. Biology: Professor W. N. Parker and Dr A. H. Trow. Anatomy: Professor A. F. Dixon. Physiology: Professor J. B. Haycraft. Materia Medica and Therapeutics: Dr. D R. Paterson. Bacteriology: Dr W. G. Savage. Public Health and Hygiene: Dr. E. Walford and Dr. W. Williams.

CARDIFF INFIRMARY.—*Staff:* Consulting Physicians: Dr. W. T. Edwards and Dr. W. Taylor. Physicians: Dr. C. T. Vachell and Dr. F. W. Evans. Surgeons: Mr. A. Sheen, Mr. T. Wallace, and Mr. P. R Griffiths. Assistant Physicians: Dr. H. R. Vachell, Dr. D. R. Paterson, and Dr. A. E. Taylor. Assistant Surgeons: Mr. A. W. Sheen, Mr. J. L Thomas, and Mr. H. G. Cook. Ophthalmic Surgeon: Mr. J. T. Thompson. Assistant Ophthalmic Surgeon: Mr. H. C. Ensor. Dental Surgeon: Mr. J. C. Oliver.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—The following Scholarships and Prizes are awarded annually:—Four University of Durham Scholarships, value £25, tenable for four years, for proficiency in Arts, awarded to full students in their first year. The Dickinson Scholarship, value interest of £400, and a Gold Medal, for Medicine, Surgery, Midwifery, and Pathology. The Tulloch Scholarship, value the interest of £400, for Anatomy, Physiology, and Chemistry. The Charlton Scholarship, value the interest of £700, for Medicine. The Gibb Scholarship, value the interest *of £500, for Pathology. The Goyder Memorial Scholarship* (at the Infirmary), value the interest of £325, for Clinical Medicine and Clinical Surgery. The Luke Armstrong Memorial Scholarship, value the interest of £680 for Comparative Pathology. The Stephen Scott Scholarship in Surgery, value the interest of £1000. Heath Scholarship: The late George Yeoman Heath, M.D., D.C.L., F.R.C.S., President of the University of Durham College of Medicine, bequeathed the sum of £4000 to found a Scholarship in Surgery, the interest to be awarded every second year; the next award will be in 1902. The Gibson Prize, interest on £225, in the department of Midwifery and Diseases of Women and Children. At the end of each session Prizes of Books are awarded in each of the regular classes. Assistant Demonstrators of Anatomy, receiving each an honorarium of £5, Prosectors, and Assistant Demonstrators of Physiology and Pathology are elected yearly. Pathological Assistants, Assistants to the Dental Surgeon, Assistants in the Eye Department, Throat and Ear Department, and Skin Department, Clinical Clerks, and Dressers are appointed every three months.

NEWCASTLE-UPON-TYNE ROYAL INFIRMARY.—Physicians: Drs. Drummond, Oliver, Limont, and Murray. *Assistant Physicians: Drs. Beattie and Bolam. Surgeons:* Dr. Hume, Mr. Rutherford Morison, Mr. Ridley, and Mr. Martin. Assistant Surgeons: Mr. H. B. Angus, Mr. J. V. W. Rutherford, Mr. Richardson, and Mr. Leech. Pathologist: Dr. Beattie. Dental Surgeon: Mr. R. L. Markham. Skin Department: Dr. Limont. Eye Department: Mr. Wardale. Throat and Ear Department: Mr. Ridley. Anæsthetist: Dr. W. D. Arnison. Surgical Registrars: Mr. John Clay and Mr. G. G. Turner. Psychological Out-patients: Dr. McDowall. The infirmary contains 280 beds. Clinical Lectures are delivered by the Physicians and Surgeons in rotation. Pathological Demonstrations are given by the Pathologist as opportunity offers. Practical Midwifery can be studied at the Newcastle Lying-in Hospital. Instruction is given in Psychological Medicine at the Northumberland County Asylum, Morpeth. A Special Course of Instruction is given in the City Hospital for *Infectious Diseases* by the Superintendent, the City Officer of Health, Mr. H. E. Armstrong.

LEEDS GENERAL INFIRMARY AND MEDICAL DEPARTMENT OF THE YORKSHIRE COLLEGE.—The Leeds General Infirmary has accommodation for 482 in-patients, medical and surgical, including 46 beds at a "semi-convalescent home" in the country. During the last year 6375 in-patients and 37,688 out-patients were treated. Clinical teaching takes place daily in the wards, and Clinical Lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, and Electrical Departments, in each of which special instruction is imparted to students A Gynæcological and Extern Obstetric Department, together with Laryngeal and Skin Clinics, are in operation. The Public Dispensary, the Hospital for Women and Children, the Fever Hospital, and the West Riding Lunatic Asylum are other medical institutions which are made use of by the Leeds students Five years ago the new buildings of the Medical School were opened by their Royal Highnesses the Duke and Duchess of York. Erected on a commanding site, close to the Infirmary, the new School of Medicine contains complete accommodation for the training of medical students upon the most approved modern methods. A very fine dissecting-room, extensive *laboratories for Physiology and Pathology*, with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large Library, and separate Museums for Pathology and Anatomy—these are some of the most striking features of the new buildings. Careful provision for the convenience of students, in the shape of a common-room, a refectory, &c., has also been made a feature of the school. The classes in Systematic and Practical Chemistry, Physics and Biology, are held in the Science and Arts Department of the College, in College-road. Two Entrance Scholarships are offered: one, of the value of 64 guineas, covering admission to all requisite lectures; and the other, of the value of 40 guineas, covering the cost of admission to the medical and surgical practice of the infirmary. Several valuable prizes are given at the end of each session. The following appointments at the infirmary are annually open to students (for some of them, *however, a registered legal qualification is required*); senior and 5 junior anæsthetists, pathological curator, resident medical officer, resident surgical officer, resident casualty officer, resident ophthalmic officer, appointed for 12 months, and eligible for re-election; resident obstetric officer and 4 house surgeons, for 12 months; 3 house physicians, for six months; 30 physicians' clerks, for six months; 32 surgeons' dressers, for six months; 16 ophthalmic and aural surgeons' dressers, for three months; 12 gynæcological ward clerks, for three months; 16 gynæcological out-patient clerks, for three months; 24 assistant physicians' clerks, for three months; 24 assistant surgeons' dressers, for three months; 8 out-patient ophthalmic and aural dressers; 32 dressers in the casualty room, for three months; 32 post-mortem clerks, for three months.

There are appointments open to students in other medical institutions in the town and also in the West Riding Lunatic Asylum.

UNIVERSITY COLLEGE, LIVERPOOL (VICTORIA UNIVERSITY): MEDICAL FACULTY.—New medical buildings are at present in course of erection, comprising departments of Anatomy, Surgery, Anatomical Museum, and Laboratory and Lecture-room accommodation for the School of Dental Surgery, Materia Medica, Toxicology, &c. These adjoin the Physiological and Pathological Laboratories, which were recently built and equipped by the generosity of the Rev. S. A. Thompson-Yates at a cost of over £30,000. These laboratories include theatres for physiology and pathology, laboratories for Microscopic, Physical, and Chemical Physiology, for Morbid Anatomy, Bacteriology, and Chemical Pathology, special rooms for research, &c., private rooms, *students' common room, and lavatories. The Chemical* Laboratories have been extended so as to provide *inter alia* more complete accommodation for medical students and those engaged in laboratory work for diplomas in Public Health. The Chair of Hygiene has secured adequate permanent accommodation in Ashton Hall, an institute adjacent to the College which contains ample class-room and laboratory accommodation for study and research. The museums of Anatomy, Pathology, and Materia Medica are furnished with complete provision for the needs of students and have recently been reorganised and revised. The museum of Hygiene accommodated in Ashton Hall has been recently established on the lines of the Parkes Museum. It contains meteorological instruments and numerous models and specimens Under the supervision of the Professor of Hygiene a course of lectures on Sanitary Science is given during the winter suitable for candidates for sanitary inspectors' certificates.

Royal Infirmary.—The Royal Infirmary, which adjoins the School, contains 300 beds with 40 special beds for the treatment of Diseases of Women. The Lying-in, Eye and Ear, Women's, Children's, Dental, and Skin Hospitals are in the immediate vicinity and their practice is open to the students of the Medical Faculty.

Fees.—The composition fees are:—£24 15s. for Preliminary Scientific Classes; £60 for the Medical Classes *required for* the Victoria, London, and other University degrees; and £70 for all the classes required for the diplomas of the Conjoint Boards. The medical composition fees are payable in two instalments at intervals of 12 months. The fee for hospital attendance at the Royal Infirmary is 40 guineas, also payable in two annual instalments.

Appointments.—Four house surgeons, three house physicians, and one house surgeon to the Thornton Wards are appointed for six months after (if necessary) competitive examination. Candidates must have a legal qualification There are also one resident and one extra casualty officer. Clinical clerks for each physician, dressers for each surgeon, and clerks to the Thornton Wards for Diseases of Women are appointed every three months. Post-mortem clerks are appointed for six weeks; all students are required to perform this duty before the schedule for the Final Examination is signed.

Fellowships and Scholarships.—Fellowships, scholarship and prizes of over £600 are awarded annually. (*a*) A Holt Fellowship in Pathology and Surgery of the value of £100 for one year is awarded annually by the medical faculty to a senior student possessing a medical qualification. The successful candidate is required to devote a year to tutorial work and investigation in the pathological department. (*b*) A Holt Fellowship in Physiology is awarded under similar conditions of the value of £100 for one year. (*c*) A Robert Gee Fellowship in Anatomy, awarded under similar conditions, also of the value of £100 for one year. (*d*) An Alexander Fellowship for Research in Pathology of the annual value of £100, renewable. (*e*) A Johnston Colonial Fellowship in Pathology and Bacteriology (£100 a year, renewable). (*f*) A John W. Garrett International Fellowship in Physiology and Pathology (£100 a year, renewable). (*g*) Two Lyon-Jones Scholarships of the value of £21 each for two years are awarded annually—a junior scholarship, open at the end of the first year of study to Victoria University students, in the subjects of the First M.B. Examinations, and a senior scholarship, open to all students in the school at the end of the second or third year of study, on the subjects of Anatomy, Physiology, and Therapeutics. (*h*) The Derby Exhibition of £15 for one year is awarded in Clinical Medicine and Surgery in alternate years. Students may compete in their fourth and fifth years. In 1901 the subject will be Clinical Surgery. (*i*) The Torr Gold Medal in Anatomy and the George Holt medal in Physiology, the Fletcher prize in Physiology (£3 3*s*. in books), the Kanthack Medal in Pathology, the Robert Gee Book Prize, of the value of £5, for Children's Diseases, and numerous Class Prizes are awarded annually.

Entrance Scholarships.—Four Robert Gee Entrance Scholarships of the value each of £25 for one year are offered annually for competition. The holder is required to take out the Course for the University Degree in Medicine.

Communications should be addressed to the Dean, Professor Paterson, M.D., University College, Liverpool.

School of Dental Surgery.—A new mechanical laboratory has recently been erected at the Dental Hospital; it is adequately equipped with all modern appliances and is under the charge of a skilled mechanic. The fees for dental education are £50 (payable in two instalments) for the Medical School curriculum; £21 payable on entrance for two years' Dental Hospital practice; £10 10*s*. for General Hospital practice (two winters). A limited number of apprentices are taken at the hospital: fee (for three years), £105. Numerous scholarships and prizes are offered: (*a*) A Fletcher Scholarship of £21 in Mechanical Dentistry; (*b*) a Phillips Scholarship of £10 10*s*. in Dental Surgery; a Councell Prize for Dental Mechanics (£5 5*s*. in books); Ash's Essay Prize (£2 2*s*.), &c.

The School of Tropical Medicine, Liverpool.—The Liverpool School of Tropical Medicine, inaugurated in 1899, is managed by a committee of appointed representatives from University College, Liverpool, the Royal Southern Hospital, the Liverpool Chamber of Commerce, and the Steamship Owners' Association. Major Ronald Ross, F.R.S., late I.M.S., is the Superintendent and Lecturer in Tropical Medicine, and the school has already done excellent work in attempting to eradicate malaria in certain colonial stations.

Prospectuses and further information may be had on application to the Registrar, University College, Liverpool.

MEDICAL DEPARTMENT OF OWENS COLLEGE (VICTORIA UNIVERSITY).—This medical school is located in a large building, which forms a part of Owens College. It is provided with large dissecting-rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. In order to give the fullest possible opportunities for teaching and investigation in the departments of Anatomy, Physiology, Pathology, and Materia Medica, an extension of the school buildings has recently been made. The greater part of the new buildings is devoted to the departments of physiology, pathology, toxicology, anatomy, and public health. The physiological department occupies more than half of the new buildings, and includes a large lecture theatre, accommodating 350 students, with preparation and diagram rooms adjacent to it, and a research laboratory fitted with the necessary apparatus for the use of advanced students, research scholars, or practitioners of medicine undertaking the investigation of some special subject. In the new pathological laboratories ample provision is made for the teaching pathology and bacteriology and for the prosecution of original research. In the toxicological department there is a large laboratory, capable of accommodating 50 students, lighted from both sides and also from the roof, completely equipped with all that is necessary for the practical teaching of toxicology; also a small laboratory for private research, containing the apparatus and fittings necessary for investigations in toxicological chemistry. In the public health department suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology. A large room is provided in the new buildings for a museum of apparatus, models, plans, and other sanitary appliances for the practical instruction of the students, together with a special library of works on State medicine, hygiene, vital statistics, and sanitary engineering. In addition, a large lecture theatre for general purposes, accommodating 250 students, has been provided, and the existing accommodation for students is supplemented by the provision of a larger common room. The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary, as well as in a fever hospital, a lunatic asylum, and a convalescent home. Medical and Surgical Clinical Classes are conducted in the infirmary, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary. The following entrance scholarships are offered for award to persons of either sex proposing to enter a medical course of study at the College:—Seaton.—One of £40, tenable for two years. Subjects: Greek and Latin Translation at sight, and Prose Composition. Credit given for knowledge of Mathematics (Geometry and Algebra); Elements of English Language, Literature, and History; French and German. Rogers.—One of £40, tenable for two years. Subjects as in Seaton. Dalton.—Two of £40, tenabl for two years. Subjects: Geometry (Euclid I.—IV., and VI., or the subjects thereof); Algebra (as far as the Binomial Theorem, inclusive). Plane Trigonometry (to Solution of Triangles); Elementary Analytical Geometry; Conic Sections. Credit given for knowledge of Classics, Elements of English Language, Literature, and History; French and German. Cartwright.—£35 per annum, tenable for three years. Subjects as in Dalton. Hulme.—£35, tenable for three years. Subjects: English Language (Grammatical Structure and Outlines of its History); English Literature (an essay on some subject of English literature); and Modern History (Outlines of English History and Geography); with at least two of the following: Latin (Translation at sight, Grammar, and Easy Composition); Greek (ditto); French (ditto); German (ditto). Credit given for knowledge of Mathematics (Geometry and Algebra). James Gaskill.—£40, tenable for two years. Subjects: Mathematics, Geometry (the substance of Euclid I.—IV. and VI.), Algebra (as far as the Binomial Theorem, inclusive), Plane Trigonometry (to Solution of Triangles), Elementary Mechanics, Chemistry. Credit given for knowledge of Classics, Elements of English Language, Literature, and History, and French and German. Manchester Grammar School.—£18 per annum, tenable for three years. The examinations for all these scholarships are held in the month of June. Kay-Shuttleworth (Sir James Phillips).—£30 per annum, tenable for three years. Subjects: Mathematics, Elementary Mechanics, Chemistry. Dauntesey Medical Scholarships.—Two Scholarships of £35 each are open to all students preparing for a medical course who shall not have attended lectures or Laboratory courses on human anatomy or physiology, or a purely medical or surgical course in the Owens College or any other Medical School in the United Kingdom. Candidates will be examined in Zoology, Botany, and Chemistry. Medals are awarded on the results of the various class examinations at the end of each session. A Platt Physiological Scholarship of £50 a year for two years is offered annually to the competition of persons whether previously students of the College or not. Two Platt Exhibitions, of the value of £15 each, to be competed for by first and second year students in the class of Physiology, and a Sidney Renshaw Exhibition in Physiology of the value of £15 to be competed for by second year students in Physiology. A Professor Tom Jones Memorial Exhibition of the value of £25, a Dumville

Surgical Prize of £15 a Turner Medical Scholarship of £20, and a John Henry Agnew Scholarship in Diseases of Children of £30 are offered annually for competition. A Professor *Tom Jones Memorial Scholarship of £100* is awarded triennially, a Bradley Memorial Scholarship in Clinical Surgery of the value of £20 and Medical and Surgical Clinical Prizes, each of the value of 6 guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the infirmary. The session commences on Oct. 1st.

Manchester Royal Infirmary (291 beds).—*Consulting Physicians: Drs. Frank Renaud, H. Browne,* and Henry Simpson. Consulting Surgeons: Messrs. George Bowring, Walter Whitehead, and James Hardie. Physicians: Drs. J. Dreschfeld, Graham Steell, Thomas Harris, and J. S. Bary. Assistant Physicians: Drs. A. T. Wilkinson and Ernest S. Reynolds. Consulting Obstetric *Physician: Dr. Lloyd Roberts. Obstetric Physician:* Dr. Archibald Donald. Surgeons: Messrs. F. A. Southam, *G. A. Wright. William Thorburn, and Joseph Collier.* Assistant Surgeons: Messrs. J. E. Platt, W. P. Montgomery, and J. W. Smith. Consulting Ophthalmic Surgeon: Dr D. Little. Ophthalmic Surgeon: Dr. Hill Griffith. Aural *Surgeon: Dr. William Milligan Consulting Dental Surgeon:* Mr. G. W. Smith. Dental Surgeon: Mr. W. A. Hooton. Pathological Registrar: *Dr. F. C. Moore.* Medical Registrar: Dr. T. N Kelynack. Surgical Registrar: Mr T. Gregory. Director of the Clinical Laboratory: Dr. W. E. Fothergill. Assistant Director of the Clinical Laboratory: Dr. C H. *Melland. Administrators of Anæsthetics:* Mr. Alexander Wilson and Mr. J. T. Smith. Assistant Medical Officer for Out Patients: Dr. C. E. Preston. Assistant Surgical Officer for Out Patients: Mr. E. W. Floyd. Medical Officer for Home Patients: Dr. A C. Sturrock. General Superintendent and Secretary: Mr. W. L Saunder. The *Winter Session commences Oct. 1st.*

The Royal Hospital, Portsmouth (founded 1847)—The number of beds is 150 During the year 1900 there were 1303 in-patients and 9191 out-patients. Physicians: Dr. James Watson and Dr. John Phillips. Surgeons: Dr. J Ward-Cousins, Dr. A. Lloyd Owen, and Mr. Henry Rundle. Assistant Physicians: Dr. D. P. McEldowney, Dr. C. C. Claremont, and Dr. L Cole Baker. Assistant Surgeons: Mr C. P. Childs, Mr. A. B Wright, and Mr J. A. M. Forde House Surgeon: Mr. W. W. Deans. Assistant House Surgeon. Mr. N. O. Beaumont. The hospital is a preparatory School of Medicine and Surgery; the attendance of pupils at this Hospital is recognised by the Examining Boards.

University College, Sheffield—Department of Medicine.—The Medical School has been incorporated by Royal Charter with Firth College and the Sheffield Technical School, under the title of University College, Sheffield An entrance scholarship of the value of £110 is awarded annually to the best candidate (if of sufficient merit) in Mathematics, Elementary Physics, Inorganic Chemistry, Latin, and English. Prizes for Clinical Medicine and Surgery of 10 guineas are offered by the Clinical Committee. Kaye Scholarship *(being the interest on £900)* for second-year students native of Sheffield is awarded annually under certain regulations. Prizes in books and certificates are awarded annually. The medical school is provided with anatomy theatre, dissecting-room, physiological laboratory, museum, library, and class rooms. New premises have been acquired *near the College for the Pathological Museum* and Laboratory and a Bacteriological Laboratory which has been completely equipped through the generosity of "a Sheffield citizen." The courses of instruction for the D.P.H. Public Health are recognised by the Royal College of Surgeons and Cambridge University. The physiological department has been entirely reconstructed and equipped in memory of the late President of the school, Mr. Wm. F. Favell The department consists of a lecture and demonstration theatre, laboratory, preparing-room, and galvanometer room, all of which are equipped with the most modern apparatus. Each student has his own laboratory bench, with gas, water, electric light, and the requisite apparatus. The course of lectures and instruction is adapted to meet the requirements of the various examining bodies. The Sheffield Royal Infirmary contains 240 beds, including Ophthalmic and Dermatological departments and post-mortem theatre, with microscopes and all the appliances for clinical research. The Sheffield Royal Hospital contains 125 beds and Dental and Ophthalmic departments, and is recognised by the examining bodies. *Perpetual fee for hospital practice* £45 in one payment; or by two instalments: £26 on entering for hospital practice, and 22 guineas within twelve months afterwards. Composition fee for lectures and practical courses 60 guineas; or in two instalments: 35 guineas at commencement of medical study and 30 guineas at beginning of the second year. Students are also admitted to the practice of the Jessop Hospital for Diseases of Women, to the Borough Fever Hospitals, and the South Yorkshire Asylum. The completely *equipped dental department has been recognised by* the examining bodies. Dr. C J. Patten has been appointed Professor of Anatomy in place of Dr. Christopher Addison. Mr. J. W. Wilfred Stokes has been appointed Demonstrator of Anatomy. Dr. Burgess has been appointed Professor of Medicine in place of Dr. Dyson appointed Emeritus Professor. Mr. A. M. Connell appointed Assistant Lecturer and Demonstrator on Pathology. Dental Department: Mr. J. Lee Pike lecturer on *Dental Mechanics,* Mr. F. G. Mordaunt Dental Anatomy and Physiology, Mr. F. Harrison Dental Surgery and Pathology, Mr. A. McWilliam Dental Metallurgy. Dental Hospital Practice in the Sheffield *Royal Hospital. Clinical Surgery,* F. J. Birks. Clinical Medicine, F. J. Birks and C. W. Smith. Simon Prize in Pathology £10, F. J. *Birks.* Entrance Scholarship, —Finch. The Winter Session will commence on Tuesday, Oct 1st, when the Introductory Address will be delivered by Sir Thomas Barlow, Bart.

Jessop Hospital for Women, Gell street, Sheffield.—The hospital is devoted to Diseases Peculiar to Women. There is also an Obstetric Department for the admission of a small number of cases. A staff of midwives connected with the hospital attend lying-in women at their own homes, and, in case of need, are assisted by the members of the *medical staff. Out-patients are attended daily.* Students can attend the practice of the hospital and be supplied with cases of midwifery. Communications should be addressed to the Secretary, York Chambers, York-street, Sheffield

Royal Devon and Exeter Hospital, Exeter.—Medical *and Surgical Staff: Consulting Physician: Dr. Drake.* Physicians: Drs. H. Davy and William Gordon. Consulting Surgeons: Messrs. A. J Cumming, T. W. Caird, and James Bankart. Surgeons: Messrs J. D. Harris, E. J. Domville, Charles E. Bell, and A C Roper. House Surgeon: Mr. P. H. Stirk. Assistant House Surgeon: Mr. Ernest J. *Manning. Junior Assistant House Surgeon:* Mr. William E. Bird. *The hospital contains 218 beds (including special* children's wards) and has a good library, museum, dissecting room, and post-mortem room. Attendance on the practice of this hospital qualifies for all the examining boards. Arrangements can be made by which students can attend Midwifery *on application to the House Surgeon.* There is also a *Private Nursing Staff* attached to the Hospital. For particulars as to fees, &c, apply to the Matron. A new wing has recently been added.

West of England Eye Infirmary, Exeter.—Physician: Dr. William Gordon. Surgical Staff: Messrs. Bankart and Tosswill. Assistant Surgeon and Registrar: Mr. Roper. Secretary: Mr. Ernest W. Toby. The infirmary contains 50 beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary. Patients for the year ending Michaelmas, 1900 2469. Total number of patients since the opening of the Infirmary in 1808 100,169. Days of admission: *Mondays, Tuesdays, and Fridays,* at 11 A.M.

Kent and Canterbury General Hospital.—Opened for the reception of patients April 26th, 1793. 59,348 in-patients and 104,200 out-patients have been admitted since the hospital was opened. The hospital contains 108 beds. Pupils of the staff are admitted to the practice of the hospital and have the use *of the library* of the *East Kent* and Canterbury Medical Society for £7 7*s*. Operation day, Thursday, 11 A.M. Physician: Dr. Henry Alex. Gogarty. Consulting Surgeon: Mr James Reid. Surgeons: Messrs Frank Wacher, T. Whitehead Reid, J. Greasley, and Sydney Wacher. Dentist: Mr R S N. Faro. House Surgeon: Mr. W. Ewart. *Assistant House Surgeon:* vacant. *Secretary:* Mr. Arthur J Lancaster Over 700 in-patients, 2000 out-patients and casualties, and 500 dental cases are attended in a year.

Royal Infirmary, Liverpool —The buildings of the new Royal Infirmary were completed and occupied as recently as 1890. They stand on the old site, adjacent to the College, but enlarged by the purchase of a fine frontage in Pembroke-place and with the Nurses' Home spread over some four acres of ground. Externally, they form a handsome and imposing group of buildings. Every available open-air space has been taken advantage of to secure good airing grounds for the patients, and the beauty of the buildings has been not a little enhanced by the numerous balconies, colonnades, and flat roofs adapted to the same purpose for both patients and resident staff. Internally no point in modern sanitary science has been omitted There are 295 beds exclusive of the Lock Hospital. The wards—some parallelograms, some circular—have walls of glazed bricks and floors of waxed oak blocks laid on an iron and cement substratum. Three operating theatres and a clinical lecture theatre have been provided and important alterations are in progress which will add still another operation room and bring them all up to the most modern requirements of surgery. There is an electrical room and provision for special kinds of baths. The out-patient department comprises rooms for the treatment and study of minor medical and surgical maladies, for diseases of the eye skin, larynx, nose, and teeth, as well as a gynæcological department. There is also a Lock Hospital. A room has been allotted to the clinical tutors, in which bacteriological investigations are made, whilst each physician and surgeon has a private room in connexion with his wards, where his clerks and dressers may write up and tabulate cases and investigate morbid products. The pathological department, which is daily becoming of more importance in medical education, has had much pains expended upon it, so as to give proper facilities for the study of morbid anatomy. It is hoped that the facilities for clinical work will be such as not merely to enable the present students to learn the practical parts of their profession thoroughly, but to attract students from overcrowded institutions where the number of pupils is far in excess of the opportunities for the bedside study of disease. There are eight house physicians and surgeons and two casualty officers (one resident) who are selected every six months from amongst the qualified students of the school. In no hospital in the country is the resident staff so comfortably lodged. Each is provided with a bedroom and a private sitting-room in addition to the music-room and dining-room, where all meet in common; a Students' Club Room is also set aside for their exclusive use. Dr. James Barr, Secretary of Medical Board, 72, Rodney-street, Liverpool.

Staff.—Consulting Physician: Dr. Waters. Physicians: Dr. Glynn, Dr. Caton, and Dr. Barr. Assistant Physicians: Dr. Bradshaw and Dr. Abram Consulting Surgeons: Mr. Hakes and Mr. Bickersteth. Surgeons: Sir W. M. Banks, Mr. R Parker, and Mr. F. T. Paul. Gynæcological Surgeon: Dr. Grimsdale. Assistant Surgeons: Mr. R. A. Bickersteth, Mr. G. G Hamilton, and Mr. W. T. Thomas. Oculist: Mr Bickerton. Laryngologist: Dr. Hunt Dermatologist: Dr. L Roberts. Dental Surgeon: Mr. Phillips. Pathologist: Dr. Boyce. Chloroformists: Mr. Fingland and Mr. Bailey. Lock Department—Surgeon: Mr. Bernard.

Liverpool Royal Southern Hospital.—Within convenient distance of the School of Medicine and contains 200 beds. There are special wards for accidents and Diseases of Children, and there are also beds appropriated to the Diseases of Women. Clinical teaching is given in the hospital and arrangements have been made to render it both thorough and systematic The members of the staff visit the wards daily and clinical lectures are given every week. Tutorial classes are also held each day at which the junior students are instructed in the methods of diagnosis and the seniors are prepared for their final examinations. The pathological department has a good laboratory attached in which the students receive practical instruction. Recently a bacteriological laboratory has been added, where students are able to obtain a practical knowledge of bacteriology in relation to medicine. In addition to the usual clinical and post-mortem clerkships, which are open to all students, the resident post of Ambulance Officer is awarded every three months to the student whom the board may consider most suited to hold it. A Scholarship of £20 is competed for annually, which has attached to it some clinical and pathological duties; and three prizes of £5 each are yearly offered for the best series of clinical reports. Fees: Perpetual £26 5*s.*; one year £10 10*s.*; six months £7 7*s.*; three months £4 4*s.* A limited number of resident pupils can be received. Terms (exclusive of fees for Hospital Practice), £15 15*s.* per quarter. The practice of the hospital is recognised by all examining bodies. For further particulars apply to the Dean, Mr. George P. Newbolt, 42, Catharine-street, Liverpool.

Staff.—Honorary Consulting Physician: Dr. John Cameron. Honorary Consulting Surgeon: Mr. Robert Hamilton. Honorary Physicians: Dr. W. Carter, Dr. W. Williams, and Dr. C. J. Macalister. Honorary Surgeons: Mr. Wm. Alexander, Mr. Robert Jones, and Mr. Geo. P. Newbolt. Honorary Consulting Physician for Tropical Diseases: Major Ronald Ross. Honorary Dermatologist: Mr. F. H. Barendt. Honorary Consulting Ophthalmic Surgeon: Mr. R. Williams. Honorary Consulting Aural Surgeon: Mr. C G. Lee. Honorary Consulting Laryngologist: Mr. W. Permewan. Honorary Medical Officer x Rays Department: Mr. C. Thurstan Holland. Pathologist: Dr. Lyn Dimond. Honorary Anæsthetist: Dr. J. G Martin. Honorary Dental Surgeon: Mr J. Royston. House Surgeon: Mr J. Gerald Sheahan. Junior House Surgeons: Dr. W. E. Herbert and Dr. J. W. Wrightson.

Liverpool Northern Hospital.—The new hospital, under the title of the David Lewis Northern Hospital, is now open and accommodation provided for 180 patients. There is a special ward for the treatment of children. An x ray and photographic department has been established, and an installation of the light treatment for lupus is in course of erection. These departments are under the charge of Dr. Arthur Walker, by whom instruction will be given. Clinical instruction will be given by the physicians and surgeons during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fees. Consulting Physician: Dr. E. H. Dickinson, M.A. Consulting Surgeon: Dr. W. Macfie Campbell. Physicians: Dr. T. Bushby and Dr. W. B. Warrington. Surgeons: Mr. Chauncy Puzey, Mr. Damer Harrisson, and Mr. R. W. Murray. Fees for hospital attendance: Perpetual, £26 5*s.*; one year, £10 10*s*; six months, £7 7*s.*; three months, £4 4*s.*; Practical Pharmacy, £2 2*s.* Students can enter to the medical or the surgical practice separately on payment of half the above fees. Arrangements can be made for a limited number of resident pupils.

Norfolk and Norwich Hospital (220 beds).—Non-resident Pupils admitted. Fees: For three months, £3 3*s.*; for six months, £5 5*s.*; as permanent pupil, £8 8*s.* Consulting Physicians: Sir P. Eade, M.D., and Sir Frederic Bateman, M.D. Consulting Surgeons: Mr. W. Cadge and Dr. Beverley. Physicians: Dr. Barton, Dr. Burton-Fanning, and Dr. Long. Surgeons: Mr. Williams, Mr. H. S. Robinson, and Mr. S. H. Burton. Assistant Surgeons: Mr. D. D. Day and Mr. H. A. Ballance. Dental Surgeon: Mr. H. F. White, House Surgeon: Mr. A. L. Vaughan. House Physician: Mr. S. G. Champion. Secretary: Mr. F. G. Hazell.

Northampton General Infirmary (established 1743; rebuilt 1793).—The number of beds is 163. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in Anatomy and Materia Medica and Practical Pharmacy. Non-resident pupils are taken at a fee of £10 10*s.*

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-on-Trent.—The New Infirmary, opened in 1869 is built on the pavilion plan, has accommodation for over 200 patients, including Children's wards special Ovarian wards, and a special department for the treatment of Diseases of the Eye. In-patients last year, 1977; out-patients, 10,812. The attendance of pupils at this infirmary is duly recognised by all the examining boards; and there are unusual facilities for acquiring a practical knowledge of the profession. Physicians: Dr. A. M. McAldowie and Dr. S. King Alcock. Surgeons: Mr. W. D. Spanton and Dr. G. Stokes Hatton. Assistant Physicians: Dr. Hubert Nicholls and Mr. John Russell. Assistant Surgeons: Dr. Wheelton Hind and Mr. Reginald Alcock. Ophthalmic Surgeon: Mr. Herbert H. Folker. Assistant Ophthalmic Surgeon: Mr. J. F. Arlidge. Dental Surgeon: Mr. A. Baines House Surgeon: Mr. H. Hartley. House Physician: Mr. T. O'Neil. Secretary and House Governor: Mr. Albert E. Boyce, F.I.S.

Wolverhampton and Staffordshire General Hospital (founded 1845; beds, 230)—A preparatory school of Medicine and Surgery. The pupils have the advantage of seeing the whole of the practice of the physicians and surgeons and are trained in clinical work by the medical and surgical staff. The attendance of pupils at this hospital is recognised by all the examining boards.

Staff.—Consulting Physician: Dr W. Millington Consulting Surgeon: Mr C A. Newnham Physicians: Dr H. Malet and Dr. C A MacMunn Surgeons: Mr T. V Jackson, Mr J O'B Kough, and Mr W H T. Winter Assistant Surgeons: Mr A H Hunt and Mr. E Deanesly. Assistant Physician: Dr J A Codd.

SUSSEX COUNTY HOSPITAL (190 beds).—During the year [illegible] been treated. The total number [illegible] on the books during 1900 was [illegible] rds ample facilities for students, possessing a large out-patient department, a library, and a well-appointed museum The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years on payment in advance of such a fee, not exceeding 20 guineas, as the Committee of Management shall direct.

Staff.—Physicians: Dr W A Hollis, Dr H S Branfoot, and Dr E Mackey Assistant Physician: Dr J F G Dill, Dr. E Hobhouse, and Dr E F Maynard Consulting Surgeons Mr. F A Humphry and Mr H P Blaker Surgeons Mr W Turner, Mr T J Verrall, and Mr R Black Assistant Surgeons. Mr H F Jowers, Mr. F J Paley, and Mr A Buck

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury and Gartside street.—The hospital contains 140 beds The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. Out-patients are seen daily at 9 A.M. at the Dispensary, Gartside-street, Manchester. Physicians: Drs Ashby and Hutton Surgeons: Mr. G A. Wright and Mr [illegible] geon: Mr J. Howson Ray. [illegible] Honorary Aural Surgeon: [illegible] ry Dental Surgeon: Mr. C H Preston. Resident Medical Officers: Mr. M C Thackray and Mr E F. Hill Medical Officer at the Dispensary: Mr H. Osborne During 1900 there were 1283 in-patients, and 13,801 out-patients were under treatment at the Dispensary.

THE MANCHESTER CLINICAL HOSPITAL FOR WOMEN AND CHILDREN, Cheetham-hill road, Manchester.—The hospital is situated near the centre of the town and contains 70 beds Out-patients are seen daily at 9.30 A.M. and the wards are visited at 11 A.M. Secretary, Mr. H. Teague, 38, Barton arcade, Manchester

SCOTLAND.

MEDICAL SCHOOLS WITH FULL CURRICULUM [1]

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The number of students varies much in the classes and subjects It is within the limit to say that about 1300 students avail themselves each year of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards.

The anatomy rooms and laboratories will open on Tuesday, Oct 1st On Tuesday, Oct. 15th, the lectures will commence.

In accordance with the statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school, in addition to the class of Practical Materia Medica and the classes of Clinical Medicine and Clinical Surgery. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

The following Order of Study is recommended as a guide to the student for a five years' course, though not enjoined:—First Year: Biology, Physics, Anatomy, Practical Anatomy, Chemistry, and Practical or Analytical Chemistry. Second Year: Anatomy, Practical Anatomy, Physiology, Practical Physiology, Surgery, and Materia Medica—the last either in this or the Third Year—and Hospital. Third Year: Practice of Medicine, Clinical Surgery, Practical Pharmacy, Clinical Medicine, Pathology, and Hospital. Fourth Year: Surgery or Clinical Surgery, Midwifery and Diseases of Women and Children, Practice of Medicine or Clinical Medicine, Medical Jurisprudence, Practical Midwifery, Operative Surgery, and Hospital Fifth Year: Classes on Special Subjects, Hospital, and Dispensary Practice.

The appointment of Resident Physician to the wards in the Royal Infirmary under the care of the Ordinary Physicians is open to those members of their clinical class who have clerked in their wards for at least six months. Six Residentships are appointed during the year for a period of six months each. Resident Surgeons are also appointed by the Ordinary Surgeons to the Hospital. In all respects the students are taught under regulations similar to those at the University of Edinburgh and the other Universities of Scotland, and they receive similar certificates at the close of each session. Moreover, the University and College authorities in Edinburgh and the governing board of the school call upon each recognised lecturer to supply them at the close of each session with a statement giving the number of students attending the class, the number of lectures or prelections delivered during the session, the class examinations held, and the general mode of conducting the class. The courses on special non qualifying subjects have for the last quarter of a century formed a marked feature of the school. Indeed, such medical subjects could be studied in Edinburgh only in this school until lately, when the University of Edinburgh appointed from the school lecturers on Diseases of the Eye, Insanity, and Diseases of Children to take charge of classes intra-murally. A list of the classes and lecturers will be found below. Special courses of instruction for dental students and for women are also included in the curriculum of this school The classes of the school are conducted in several separate buildings, such as at Surgeons' Hall, Minto House, Nicolson-square, and the New School, Bristo-street.

Lecturers and fees.—Winter Session: Anatomy, Practical Anatomy, and Demonstrations, Drs Ryland Whitaker and R. J. A Berry (£3 5s and £4 4s); Chemistry (Practical, &c), Mr. King, Mr I. Macadam, and Mr Gemmell*; Physiology (Institutes of Medicine), Dr. Noël Paton (£3 5s); General Pathology, &c, Drs. Bruce, Russell, Shennan, and Stuart McDonald (£3 5s); Botany, Mr. R. Turnbull; † Biology, Mr. R. Turnbull and Mr. A. T. Masterman; Zoology, Mr Masterman; Bacteriology, Dr Taylor Grant; Practice of Physic. Drs. James, Affleck, Bramwell, Gibson, Philip, Graham Brown, R A. Fleming, and G Lovell Gulland (£3 5s.); Surgery Messrs Caird, Hodsdon, Shaw Maclaren, Thomson, Wallace, and Miles (£3 5s); Materia Medica, &c, Drs Craig,† and Lockhart Gillespie (£3 5s); Midwifery, &c, Drs. Hart, Murray, and Haultain (£3 5s); Medical Jurisprudence, &c, Dr. Littlejohn and Dr. Aitchison Robertson (£3 5s); Natural Philosophy, Dr. Turner (£3 5s); Hospital Practice (Edinburgh Royal Infirmary): Physicians, Drs Affleck, Smart, James, and Croom; Surgeons, Drs. Maclaren and MacGillivray, Mr. Cotterill and Mr Caird (perpetual ticket, £12 12s); Clinical Medicine, Drs Affleck, Smart, James, Byrom Bramwell, and Croom (Diseases of Women) (£3 5s); Clinical Surgery, Dr. Maclaren, Dr Macgillivray, Mr Cotterill, and Mr. Cathcart (£3 5s.); Diseases of Children, the staff of the Sick Children's Hospital (£2 2s); Diseases of the Skin, Dr. Stirling† (£2 2s), Diseases of the Chest, Dr. Philip† (£2 2s.); Vaccination, Drs. Husband,† Buist,† and Cadell (£1 1s); Diseases of Ear, Nose, and Throat, (£2 2s.); Diseases of the Eye, Dr. G. Mackay,† and Dr. Sym† (£2 2s); Gynæcology, Drs Croom (Systematic), Brewis (Clinical), and Berry Hart (Advanced), (£2 2s); Summer Session Practical Anatomy and Demonstrations, Drs. Ryland Whitaker and R J. A. Berry (£2 2s); Practical Physiology, Dr. Paton (£3 3s); Biology, Mr. Turnbull and Mr Masterman‡ (£3 3s); Botany, Mr. Turnbull; Practical Chemistry and Analytical Chemistry, Messrs King, I Macadam, and Gemmell§; Practical Bacteriology, Dr Shennan and Dr. Taylor Grant; Diseases of the Eye, Dr. Mackay‡ (£2 2s); Diseases of the Skin, Dr Stirling (£2 2s); Medical Psychology and Insanity, Sir J. Batty Tuke (£2 2s.); Medical Jurisprudence, Drs Littlejohn and Aitchison Robertson; Gynæcology, Drs. Brewis and Haultain (£2 2s); Midwifery, Drs. Croom, Hart, Barbour, and Ferguson (£3 5s); Operative Surgery, Messrs. Caird,

---

[1] For Scholarships see p. 703, et seq

Hodsdon, Shaw, McLaren, Alexis Thomson, and David Wallace (£3 3*s*); Practical Pathology, Drs. Bruce, Russell, and Shennan (£3 3*s*); Physics, Dr. Turner ‡ (£3 3*s*.); Practical Medicine and Physical Diagnosis, Drs. James, Gibson, Philip, Fleming, and Lovell Gulland (£3 3*s*.); Practice of Medicine, Drs. Bramwell, Gibson, and Philip (£3 3*s*.); Medical Electricity, &c., Dr. Turner (£2 2*s*.); Diseases of the Circulation, Dr. Gibson (£2 2*s*.). Neurology, Dr. Bruce; Diseases of the Nervous System, Dr. Graham Brown; Practical Bacteriology, Dr. Shennan and Dr. Taylor Grant.

Special Classes for Women, Winter Session: Practical Anatomy and Demonstrations, Dr. Ryland Whitaker (£4 4*s*.); Chemistry (Lectures and Practical), Mr. Ivison Macadam (£3 5*s* and £3 3*s*); Practice of Physic, Drs. Philip and Graham Brown (£3 5*s*.); Surgery, Mr. Thomson and Mr. McLaren (£3 5*s*); General Pathology, Dr. Russell (£3 5*s*); Physiology (Institutes of Medicine), Dr. Noël Paton (£3 5*s*.); Practical Pathology, Dr. Bruce, &c. (£3 5*s*.); Materia Medica, &c., Dr. Craig (£3 5*s*); Clinical Medicine, Dr. Bramwell, Royal Infirmary (£3 5*s*.); Clinical Surgery, Royal Infirmary (£3 5*s*.); Physics, Dr. Dawson Turner (£3 3*s*); Biology, Mr. Turnbull (£3 3*s*); Diseases of Children, the staff of the Sick Children's Hospital (£2 2*s*.); Vaccination Dr. Husband and Mr. Cadell (£1 1*s*); Practical Gynæcology, Dr. Brewis (£2 2*s*.). Summer Session: Practical Anatomy, Dr. Ryland Whitaker and Mr. Hardie (£2 2*s*); Practical Chemistry, Mr. Ivison Macadam (£3 3*s*); Materia Medica, &c., Dr. Craig (£3 3*s*); Operative Surgery and Surgical Anatomy, Mr. Alexis Thomson and Mr. McLaren (£3 3*s*.); Materia Medica and Therapeutics, vacant (£3 3*s*); Midwifery and Diseases of Women, Dr. R. Milne Murray (£3 5*s*.); Medical Jurisprudence and Public Health, Dr. Harvey Littlejohn (£3 5*s*.); Clinical Medicine and Clinical Surgery, Royal Infirmary (£3 5*s*.); Practical Physiology and Histology, Dr. Paton (£3 3*s*); Practical Pathology, Dr. Russell (£3 3*s*); Biology, Mr. Turnbull (£3 3*s*.); Physics, Dr. Dawson Turner (£3 3*s*); Diseases of Children, the Staff of the Sick Children's Hospital (£2 2*s*); Ophthalmology, Dr. Mackay (£2 2*s*.); Insanity, Sir J. Batty Tuke (£2 2*s*.); Practical Gynæcology, Dr. Brewis (£2 2*s*.).

The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £150, payment of which is distributed over the period of study.

Further particulars regarding the school, also its calendar, may be had on application to Mr. R. N. Ramsay, the Secretary, 24, Forrest-road, Edinburgh.

* Lectures, £3 5*s*.; Practical, £3 3*s*.; Analytical, £2 a month, or £5 for three months. † Also in Summer Session. ‡ Also in Winter Session. § Practical, £3 3*s*.; Analytical, £2 a month, or £5 for three months.

N.B.—Where two or more lecturers appear as teaching the same subjects their lectures are not conjoined, but each gives an independent course.

ANDERSON'S COLLEGE MEDICAL SCHOOL, Glasgow.—This medical school was founded in the year 1800. It has given thirteen professors to the University of Glasgow. The following courses are given, which qualify for all the licensing boards and for the Universities of London, Durham, Ireland, Edinburgh, and Glasgow (the latter two under certain conditions):—In winter: Anatomy, Professor A. M. Buchanan, M.A., M.D.; Chemistry, Professor J. Robertson Watson, M.A.; Physics, Professor Peter Bennett; Botany, Professor B. G. Cormack, M.A., B Sc.; Zoology, Professor Geo. Bell Todd, M.B.; Physiology, Professor W. Ernest Thomson, M.A., M.D.; Surgery, Professor T. Kennedy Dalziel, M.B.; Practice of Medicine, Professor R. S. Thomson, M.D., D.Sc. Diseases of Women, Professor John Edgar, M.A., B.Sc., M.D.; Materia Medica, Professor R. Barclay Ness, M.A., M.B.; Ophthalmic Medicine and Surgery, T. Spence Meighan, M.D.; Aural Surgery, J. Galbraith Connal, M.B.; Diseases of Throat and Nose, John Macintyre, M.B. In summer: Anatomy, Practical Anatomy and Osteology, Practical Chemistry, Physics, Zoology, Practical Materia Medica and Pharmacy, Practical Physiology, Operative Surgery, Botany, Ophthalmic Medicine and Surgery, also Medical Jurisprudence (Professor Carstairs Douglas, B.Sc., M D.), and Mental Diseases (Dr. Carswell), and Aural Surgery. The Chemical Laboratory is open daily from 10 to 6. The Dissecting-room is open in winter from 9 A.M. to 6 P.M., and in summer from 6 A.M. to 6 P.M. The students are assisted in their dissections by the Professor and Demonstrators, by whom frequent examinations and demonstrations on the parts dissected are conducted. The supply of subjects for dissection is ample, and students are consequently provided with parts as soon as they may be ready for them. The Dissecting-room is provided with a complete series of dissected specimens, mounted in plaster of Paris, illustrating the anatomy of the human body. Candidates for the licence in Dental Surgery can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are conducted at the Glasgow Dental Hospital and School.

The new buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, within two minutes' walk of it, and four minutes' walk of the University. Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Physiology, Practical Pharmacy, and Operative Surgery. There are also provided a large library and reading-room and a students' recreation-room.

Fees.—For each course of Lectures (Anatomy, Ophthalmic Medicine and Surgery, Aural Surgery, Diseases of Throat and Nose, and Mental Diseases excepted), first session, £2 2*s*.; second session (in Anderson's College), £1 1*s*.; afterwards free. For Practical Classes (except Anatomy)—viz., Chemistry, Botany, Zoology, Physiology, Pharmacy, and Operative Surgery—first session, £2 2*s*.; second session, £2 2*s*. Reduced joint fees in Zoology and in Botany, for Lectures and Practical Class when taken in same summer session, £3 3*s*.; for either course separately, £2 2*s*. Anatomy Class Fees: Winter, first session (including Practical Anatomy), £4 4*s*.; second session (including Practical Anatomy), £4 4*s*.; third session, £2 2*s*. To those who have had the necessary courses of Practical Anatomy the fee will be £1 1*s*. Summer, Lectures and Practical Anatomy, £2 12*s*. 6*d*.; Lectures alone, £1 11*s*. 6*d*.; Practical Anatomy alone, £1 1*s*.; Osteology and Practical Anatomy, £2 12*s*. 6*d*.; Osteology alone, £1 11*s*. 6*d*. Students who have attended classes at other schools, and who desire to pursue their studies at Anderson's College Medical School, will be admitted to such classes as they may have attended elsewhere at the reduced fees. Ophthalmic Medicine and Surgery (including Hospital Practice), Aural Surgery, Diseases of Throat and Nose, and Mental Diseases, £1 1*s*. Matriculation Fees: Winter, 10*s*. to those taking out two or more classes; 5*s*. to those taking out only one class. The fee of 10*s*. represents a combined fee for the winter and summer sessions. Summer, 5*s*., except to those who have paid a fee of 10*s*. for the Winter Session.

Royal Infirmary.—Fees: Hospital Practice and Clinical Instruction, first year, £10 10*s* ; second year, £10 10*s*.; afterwards free. Six months, £6 6*s*.; three months, £4 4*s*.; Pathology, both courses, £3 3*s*. Vaccination Fee, £1 1*s*.

Western Infirmary. — Fees: Hospital Practice and Clinical Instruction, first year, £10 10*s*.; second year, £10 10*s*.; afterwards free. Six months, £7 7*s* ; three months, £4 4*s*. Pathology, first course, £3 3*s*.; second course, £2 2*s*. Practical Pathology, first course, £3 3*s*., second course, £2 2*s*. Vaccination Fee, £1 1*s*.

Eye Infirmary.—Fee: Hospital Practice and Clinical instruction, six months, £1 1*s*.

Certificates of attendance on the lectures at Anderson's College Medical School are received by the Universities of London, Durham, Ireland, Edinburgh, and Glasgow (the latter two under certain conditions); by the Royal Colleges of Physicians of London and Edinburgh; by the Royal Colleges of Surgeons, England, Edinburgh, and Ireland; by the Royal College of Physicians of Ireland; by the Faculty of Physicians and Surgeons of Glasgow; by the Society of Apothecaries, London; and by the Army, Navy, and East India Boards. Communications relating to the Medical School to be addressed to the Secretary of the Medical Faculty, Anderson's College Medical School, Dumbarton-road, Partick, Glasgow. Communications relating to the Preliminary Examination in General Education to be addressed to Mr. Alexander Mackay, LL.D, Educational Institute Office, 40, Princes-street, Edinburgh. Communications relating to the Triple Qualification to be addressed to Mr. Alexander Duncan, LL.D., Faculty Hall 242, St. Vincent-street, Glasgow. Communications relating to the Dental School to be addressed to Mr. D. M. Alexander, 97, West Regent-street, Glasgow

The Kerr Bursary in Anatomy (value £10) is open to students of the Junior Anatomy Class during Winter Session 1901-1902.

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—This College was incorporated in 1889. The Glasgow Royal Infirmary was founded in 1791. The Faculty of Medicine of the College occupies new buildings erected for the purposes of a medical school, adjoining and communicating with the Royal Infirmary. The Laboratories, Museums, and Lecture-rooms are equipped and adapted to modern scientific requirements. Recent additions consist of Public Health, Practical Zoology, and Bacteriological Laboratories. The Royal Infirmary, which is at the service of the College for the purpose of clinical and practical instruction, is one of the largest general and special hospitals in the kingdom. It has nearly 600 beds, and will almost immediately have considerably over 600. It has special wards for Diseases Peculiar to Women, for Venereal Diseases, Erysipelas, Burns, and Diseases of the Throat and Nose. At the Dispensary special advice and treatment are given in diseases of the Eye, Ear, Teeth, and Skin, Women, Throat and Nose, in addition to the large and varied number of ordinary medical and surgical cases—over 46,000 per annum—which in a great industrial centre daily require attention. Students of the College and Hospital get the benefit of dispensary experience free of charge. All appointments are open There are five Physicians' and seven Surgeons' Assistants, who board in the hospital free of charge and act in the capacity of House Physicians and House Surgeons. These appointments are made for six months and are open to gentlemen who have a legal qualification in Medicine or Surgery, and preference is given to the students of this College and Hospital. Clerks and Dressers are appointed by the Physicians and Surgeons. From the large number of cases of acute disease and accidents of varied character received into this hospital these appointments are very valuable. In the Pathological Department assistants are also appointed. The session will open with an [illegible] Institution in West Regent-street having been amalgamated with the Royal Infirmary the usefulness of this department is very much increased, and greater opportunities are afforded to students for the practical study of Diseases of the Eye. Dr. Ramsay, the ophthalmic surgeon, attends the Royal Infirmary every Monday, Wednesday, and Friday at 12 noon, and daily at the Institution in West Regent-street from 1 to 2 o'clock. Students can attend both without payment of any additional fee. Lectures are delivered twice a week during the winter session. Fee for the course, £2 2*s*.

The fee for each class is £2 2*s*, except for Anatomy, Winter Session, which is £4 4*s*. Pathology £4 4*s*, Zoology £4 4*s*., Botany £3 3*s*. Practical Physiology, £3 3*s*., and for Physics, which is £2 4*s* 6*d*., and certain extra classes, for which the fee is £1 1*s*. The hospital fee (including clinical lectures) is £21 for a perpetual ticket. The classes in St. Mungo's College and in the Glasgow Royal Infirmary are for male students exclusively. The fees for all the lectures, including hospital attendance, necessary for candidates for the Diplomas of the English or Scotch Colleges of Physicians and Surgeons amount to £72. Further particulars can be obtained from a syllabus which can be obtained free on application to the Dean, 86, Castle-street, Glasgow.

GLASGOW WESTERN MEDICAL SCHOOL.—This School is situated in University-avenue, close to the University and Western Infirmary. Lectures and Demonstrations are given on Chemistry, on Physics, on Zoology, on Anatomy, on Surgery, on Physiology, on Midwifery and Gynæcology, on Pathology, on Medicine, and on the Eye.

Class Fees.—For each course of Lectures the fee is £2 2*s*. or in some cases £1 1*s*. There is no matriculation fee.'

QUEEN MARGARET COLLEGE, University of Glasgow.—Queen Margaret College was founded in 1883 by the Glasgow Association for the Higher Education of Women (instituted in 1877), and handsome buildings and grounds near the University were presented to the College in 1884 by Mrs. John Elder. In 1890 a School of Medicine for women was added to its Arts Faculty. In 1892, when the Universities Commissioners issued an ordinance empowering the Scottish University Courts to make provision for the instruction of women, the Council of the College and Mrs. Elder transferred to the University the College, its buildings, grounds, and endowments, on condition that these should be devoted to the maintenance of University classes for women only. The College then became the women's department of the University of Glasgow; its classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curriculum, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. They have access to the University Museum and can borrow books from the University Library, besides having a library of reference in Queen Margaret College. The number of students enrolled in session 1900-1901 was 350, of whom 73 were studying medicine and the rest arts or science. The School of Medicine is a special feature of the College and gives full preparation for the medical degrees of the University. In July, 1894, for the first time in the history of any Scottish university, women students graduated in medicine at the "capping" in Glasgow University. 63 women have now taken the degree of M.B., C.M. or M.B., Ch.B. of the University of Glasgow. Excellent facilities for clinical work are given in the Royal Infirmary and other hospitals. By a gift of £5000 granted for the purpose by the Bellahouston Trust the University Court was enabled to add to the College a large building for the study of Anatomy and Physiology, which was opened in October, 1895. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine; and by an ordinance of the Universities Commissioners women are admitted to certain University bursaries, scholarships, and fellowships. A house of residence for the students of the College coming from a distance was opened by the Queen Margaret Hall Co., Limited in October of 1894.

UNIVERSITY COLLEGE Dundee.—This College is one of the constituent colleges of the University of St. Andrews. The complete medical curriculum can be taken in Dundee. For classes, fees, &c, see under University of St Andrews.

ROYAL INFIRMARY.—The Infirmary contains 300 beds, including special wards for the Diseases of Women, Children, Eye, Ear and Throat, and Lock cases. There is also a Maternity Department, in- and out-door. There were during last year 10 517 out-patients and 6676 home patients. The Royal Infirmary offers exceptional facilities for practical work to students. Appointments: Four qualified Resident Medical Assistants are appointed every six months. Clinical Clerks and Dressers are attached to the Physicians and Surgeons, and students are appointed as assistants in the Pathological Department. There are in connexion with the clinical courses Tutorial Classes in Medicine and Surgery. Instruction is also given in Practical Pharmacy and Materia Medica and in Practical Dentistry. Full information can be obtained from Dr. Fraser, Medical Superintendent.

ROYAL ASYLUM.—Lectures on Mental Diseases and clinical instruction in connexion with University College, Dundee (University of St. Andrew's), are given at the University and at the Royal Asylum by Dr. Rorie. There are two paid qualified Resident Assistants and two unpaid Resident Clinical Assistants. The last Summer Session began on April 24th, 1901, and the course consisted of 12 Lectures at University College and 14 Clinical Lectures and Demonstrations at the Royal Asylum Geo. McNeill gained First Prize and L. D. Gairdner gained Second Prize. Present Medical Assistants: Wm Tuach M.B., Ch.B., and W. L. G. Anderson, M.B, Ch B Clinical Assistant: Mr. Leslie. The next session will begin on April 24th, 1901.

ABERDEEN ROYAL LUNATIC ASYLUM.—Contains, with hospital attached to main institution and Agricultural Branch, about 950 beds. Medical Superintendent: Dr. William Reid. Assistant Physicians: Dr. J H. Mackay, Dr. Arthur L. Sutherland, and Dr. L B Green. Clerk, Treasurer, and Factor. Mr. J. B. Findlay. Clinical instruction is given to students during three months in summer.

ABERDEEN ROYAL INFIRMARY.—Contains 240 beds. Consulting Physician: Dr. P. Blaikie Smith. Physicians: Dr. Angus Fraser, Professor Finlay, and Dr. George M. Edmond. Assistant Physicians: Drs. John Gordon, A. H. Lister, and Ashley W Mackintosh. Consulting Surgeons: Professor Alexander Ogston, Drs. J. C. O. Will and R. J. Garden. Surgeons: Drs. J. McK. Booth, J. S Riddell, and John Marnoch. Assistant Surgeons: Drs. W. Sinclair, H. M. W Gray, and John W. Milne Ophthalmic Surgeon: Dr. C. H. Usher. Gynæcologist: Professor W. Stephenson.

Pathologist: Professor David James Hamilton. Assistant Pathologist: Dr. G. M. Duncan. Dental Surgeon: Dr. J. M. P. Crombie. Anæsthetist: Dr. J. J. Y. Dalgarno. Assistant ditto: Dr. W. R. Pirie. Medical Electrician: Dr. J. R. Levack. Clinical Registrar and Lecturer on Diseases of the Skin: Dr. J. F. Christie. Medical Superintendent: Dr. Charles Angus. Clerk and Treasurer and Factor for the Hospital Lands: Mr. John B. Findlay.

HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

ROYAL INFIRMARY, Edinburgh.—Beds are set apart for clinical instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in the medical department on Diseases of Women, Physical Diagnosis, and on Diseases of the Skin; and in the surgical department on Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, and the Skin, and also to cases of Incidental Delirium or Insanity. Three wards are specially set apart for Clinical Instruction to Women Students. Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6*s.*; six months, £4 4*s.*; three months, £2 2*s.*; monthly, £1 1*s.* Separate payments amounting to £12 12*s.* entitle the student to a perpetual ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows:—1. Resident physicians and surgeons are appointed, and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident house physicians and surgeons are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department are appointed by the pathologist.

Staff: Medical Department.—Consulting Physicians: Dr. George W. Balfour, Dr. Claud Muirhead, and Dr. J. O. Affleck. Consulting Gynæcologist: Dr. J. Halliday Croom. Professors of Clinical Medicine: Dr. T. R. Fraser, Dr. W. S. Greenfield, and Dr. John Wyllie. Ordinary Physicians and Lecturers on Clinical Medicine: Dr. Andrew Smart, Dr. Alex. James, Dr. Byrom Bramwell, and Dr. Geo. Gibson. Gynæcologists: Professor A. R. Simpson and Dr. D. Berry Hart. Physician for Diseases of the Skin: Dr. Allan Jamieson. Medical Electrician: Dr. Dawson Turner. Assistant Physicians: Dr. Alex. Bruce, Dr. R. W. Philip, Dr. William Russell, Dr. Murdoch Brown, Dr. G. Lovell Gulland, Dr. J. J. Graham Brown, Dr. Francis D. Boyd, and Dr. A. Fleming. Assistant Gynæcologists: Dr. A. H. F. Barbour, Dr. Milne Murray, and Mr. N. T. Brewis. Assistant Physician for Diseases of the Skin: Dr. Norman Walker. Assistant Medical Electrician: Dr. Hope Fowler. Medical Registrar: Dr. A. Lockhart Gillespie.

Surgical Department.—Consulting Surgeons: Dr. P. H. Watson, Mr. Joseph Bell, Mr. A. G. Miller, and Dr. P. H. Maclaren. Consulting Dental Surgeon: Dr. John Smith. Consulting Ophthalmic Surgeon: Dr. Argyll Robertson. Regius Professor of Clinical Surgery: Mr. Annandale. Professor of Surgery: Mr. Chiene. Ordinary Surgeons: Dr. C. W. MacGillivray, Mr. J. M. Cotterill, and Mr. C. W. Cathcart. Ophthalmic Surgeons: Mr. George A. Berry and Dr. George Mackay. Surgeon to Ear and Throat Department: Dr. P. MacBride. Assistant Surgeons: Mr. F. M. Caird, Mr. Hodsdon, Mr. J. Shaw M'Laren, Mr. D. Wallace, Mr. Alexis Thomson, Mr. Alexander Miles and Mr. J. W. Dowden. Assistant Ophthalmic Surgeons: Dr. William George Sym and Dr. J. V. Paterson. Assistant Surgeon to the Ear and Throat Department: Dr. R. M'Kenzie Johnston. Dental Surgeon: Mr. William Guy. Pathologist: Dr. D. A. Welsh. Assistant Pathologists: Dr. Stuart M'Donald and Dr. Theodore Shennan. Surgical Registrar: Dr. Scott Carmichael. Superintendent: Colonel W. P. Warburton, M.D., C.S.I.

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh.—This hospital, which has been recently built, contains 120 beds, and is fitted with every modern improvement. A fully-equipped out-patient [illegible] (medical and surgical) is conducted [illegible] adjoining the hospital. Systematic co [illegible] which qualify for graduation in the E [illegible] and elsewhere, are given from time to time throughout the year by the staff. Students may enter at any time. Full particulars can be obtained from the Registrar at the hospital.

EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH, 6, Cambridge-street, Lothian-road.—The Infirmary has been entirely re-arranged and greatly improved by recent structural alterations and the electric light introduced; also the electric power is used for illumination and cauterising purposes in all departments. Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for outdoor patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 P.M. for outdoor Ear Nose and Throat Patients. Special Practical Ophthalmoscopic Classes by arrangement. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Consulting Surgeon: Dr. Joseph Bell. Surgeons: Dr. G. Hunter Mackenzie, Dr. William George Sym, Dr. Logan Turner, Dr. Malcolm Farquharson, Dr. John Cumming, and Dr. J. V. Paterson. Dental Surgeon: Mr. G. W. Watson. Treasurer and Secretary: Mr. J. P. Watson, W.S., 13, Hill-street.

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 420. Special wards are set apart for Diseases of Women and for Affections of the Skin. In the out-patient department there are special cliniques for Diseases of Women and for Diseases of the Throat, Ear, and Teeth. The Clinical Courses are given by the Physicians and Surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, also post-graduate courses, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Ten resident assistants are appointed annually, without salary, from those who have completed their course. The fee for the hospital practice, including the various courses of clinical instruction, is 20 guineas in one payment, or in two equal instalments for the first and second year; for six months, 7 guineas; and for three months, 4 guineas.

Staff.—Honorary Consulting Physicians: Dr. G. P. Tennant and Sir W. T. Gairdner, K.C.B. Visiting Physicians: Professor T. McCall Anderson, Dr. J. Finlayson, Dr. S. Gemmell, and Dr. R. Stockman. Physicians for Diseases of Women: Professor M. Cameron and Dr. W. L. Reid. Assistant Physicians: Dr. J. Alexander, Dr. W. G. Dun, Dr. R. S. Thomson, and Dr. G. Dickson. Dispensary Physicians: Dr. R. B. Ness, Dr. W. MacLennan, Dr. W. R. Jack, Dr. H. E. Jones, Dr. Hugh Galt, and Dr. Jas. Carslaw. Dispensary Physicians for Diseases of Women: Dr. R. Kirk, Dr. G. A. Turner, Dr. J. M. M. Kerr, and Dr. E. H. L. Oliphant. Honorary Consulting Ophthalmic Surgeon: Dr. T. Reid. Honorary Consulting Surgeon: Dr. Geo. Buchanan. Visiting Surgeons: Dr. A. Patterson, Sir Hector C. Cameron, Professor W. Macewen, Professor J. C. Renton, and Dr. T. T. Beatson. Assistant Surgeons: Dr. T. K. Dalziel, Dr. J. H. Nicoll, Dr. D. Macartney, Dr. R. Kennedy, and Dr. A. A. Young. Dispensary Surgeons: Dr. G. B. Buchanan, Dr. J. Morton, and Dr. G. H. Edington. Extra Dispensary Physicians: Dr. H. E. Jones, Dr. H. Galt, and Dr. J. Carslaw. Dispensary Aural Surgeon: Dr. T. Barr. Dispensary Throat Surgeon: Dr. J. W. Downie. Vaccinator: Dr. J. W. Nicol. Pathologist: Professor R. Muir. Assistant Pathologist: A. R. Ferguson. Dental Surgeon: W. D. Woodburn. Medical Superintendent: Dr. D. J. Mackintosh.

ROYAL HOSPITAL FOR SICK CHILDREN, Glasgow, situated at Garnethill.—This Hospital was opened in December, 1882, and is now available to medical students for clinical instruction in the diseases peculiar to childhood. The hospital includes 80 beds for non-infectious cases only. A specially designed Dispensary, or Out-patient Department, was opened in October, 1888 Classes are formed both at [illegible] beginning of the University [illegible] be enrolled at any time. [illegible] to both Hospital and [illegible] to the House Surgeon, [illegible] Surgeon: [illegible] Rowan, [illegible] Walker, [illegible] and John Gilchrist, M B, C M Pathologist: Hugh Walker, M B, C.M. Electrician: John Gilchrist, M B, C M, House Surgeons: Thomas Kirkwood, M B, C M., and Alexander Garrow, M B, Ch B This institution is the Ophthalmic Department of the Royal Infirmary. A post graduate course is given by Dr. [illegible] mber and December [illegible] mmer session to stude [illegible] d in winter to studen [illegible] who take the class.

GLASGOW EYE INFIRMARY, Berkeley street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824 The Infirmary now consists of two large buildings—that in Berkeley-street being occupied as the Infirmary proper, and that in Charlotte-street (new buildings opened June, 1894) as a dispensary The Infirmary is devoted exclusively to the treatment of Diseases of the Eye, and is intended primarily to provide treatment, and, when necessary, board and lodging, for those who are unable to do so for themselves The average number of new patients for the last ten years has been 16,103 8 and the total number of cases treated in 1900 was 20 802. The Medical Staff is as follows —Surgeons: Thomas S Meighan, M D., A. Freeland Fergus, M.D., William Robertson, M D, Andrew Wilson, M.B, C M, James Hinshelwood, M A, M.D, Leslie Buchanan, M D. Assistant Surgeons: A. Lewis M'Millan, M D; W. Ernest Thomson, M A, M.D.; Henry L G. Leask, M D; W. Cochrane Murray, M.B, C M.; Brownlow Riddell, M.D, James D. Cochran, M.B, Ch B. Pathologist: Leslie Buchanan, M.D House Surgeon: Arthur J. Ballantyne, M.B, Ch B. Assistant House Surgeon: John Strathern, M.B., Ch B.

Regulations as to Attendance of Students—(1) Gentlemen may attend as students on payment to the treasurer of the following fees:—For six months £1 1*s*, twelve months £2 2*s* (2) All students when duly entered in the Infirmary Register may attend the clinical instruction of any or every member of the medical staff on production of their tickets. The days on which the surgeons respectively attend to receive patients may be ascertained at the Infirmary. Students have the privilege of being present in the Dispensaries at such hours as are arranged. They may enter the wards along with the surgeon whose clinique they are attending when he visits his patients They may also be present at operations under the sanction of the surgeon operating, but no student may enter the wards or operating-room except under the aforesaid regulation Students may be allowed the use of the journals and case-books for examination on applying to the House Surgeon. The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine Secretary and acting Treasurer: William George Black, 88, West Regent street. Medical session begins April.

IRISH SCHOOLS OF MEDICINE.[1]

QUEEN'S COLLEGE SCHOOL OF MEDICINE Belfast.—Ten Junior Scholarships have been founded in the Faculty of Medicine of the annual value of £20 each. Two are tenable by matriculated students, of the first, second, third, fourth, and fifth years of their course respectively. The examinations for Scholarships take place at the commencement of the session. Class Prizes are awarded at examinations which take place at the close of the session. The Exhibitions, &c., of the Royal University of Ireland are also open to students. Lectures in Medicine at Queen's College, Belfast, will commence on Oct. 16th and end on March 22nd. The Summer Medical Classes will begin on May 1st, except Botany, which begins on April 2nd. The new Chemical Buildings contain, in addition to a large class room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes, balance room, &c, provided with all modern appliances. Special facilities are given to those who wish to pursue original research. The Anatomical Department contains a large and well-lighted, dissecting-room, a lecture room, a professor's and demonstrator's room, a bone room, and a laboratory for micros [illegible] medical museum is in [illegible] department (opened in [illegible] lighted class room for [illegible] fitted with motor and [illegible] lantern projection; (2) a laboratory for chemical physio- [illegible] (4) a dark-room; (5) private [illegible] trifuge room. The pathologi- [illegible] tment opportunity is afforded for research in pathology and bacteriology. The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the corporation in connexion with water supply, sewage disposal, meat and milk supply, the diagnosis of cases of infectious diseases, &c The certificate issued to members of the class in bacteriology qualifies for the D P H degree. The pharmaceutical laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines. Clinical instruction is given at the Royal Hospital, the medical staff of which is as follows:—Physicians: Professor Whitla, Professor Lindsay Dr H L McKisack, and Dr W Calwell Obstetrical Physician and Gynæcologist. Professor Byers Assistant Gynæcologist: Mr. H. Monypenny Surgeons: Dr J W. Browne, Dr T K. Wheeler, Mr A B Mitchell, and Professor Sinclair. Assistant Surgeons: Mr Robert Campbell and Dr T S Kirk Assistant Physician Dr W. B. McQuitty. Ophthalmic and Aural Surgeon: Dr J. Nelson Pathologist Dr J. L. Smith The Ulster Hospital for Diseases of Women and Children, the Maternity Hospital, the Ophthalmic Hospital, the Ulster Eye, Ear, and Throat Hospital, the Hospital for Sick Children, and the District Lunatic Asylum are open to students A pamphlet containing full information can be had free on application to the Registrar, Queen's College, Belfast.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Cork—The building is provided with a very large, well-ventilated dissecting-room, w[illegible] and pharmacent[illegible] and pathologica[illegible] and obstetrical [illegible] appointed physical, chemical, and biological laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden The plant houses are well filled with plants and are open to the students in the class of Botany.

Fees—For Practical Anatomy and for Practical Chemistry, £3 each course; for Anatomy and Physiology, £3 first course, and £2 for each subsequent course. Other medical classes, £2 first course, and £1 each subsequent course

Eight scholarships (value about £30 each), as well as several exhibitions and class prizes, are open to students in their first four years and the Blayney Scholarship, value £35, and a Senior Exhibition to students in their fifth year.

Students can attend the North and South Infirmaries, the Cork Union Hospital, the Cork Fever Hospital, the County and City of Cork Lying in Hospital, the Cork Maternity, the County and City of Cork Hospital for Diseases of Women and Children, the Cork Eye Ear, and Throat Hospital, and the Cork District Lunatic Asylum.

Staff—Physicians Dr. D D Donovan and Dr. E. Magner. Surgeons: Dr Cotter, Dr. C Y Pearson, Dr N. J. Hobart, and Dr D J O'Mahony Assistant Physician: Dr. R B.

Dalton. Assistant Surgeons: Dr. J. Dundon and Dr. R P. Byrne. Pathologist: Dr. R. B. Dalton. House Surgeon: Dr. D. Murphy. Surgeon Dentist: Mr. H. O'Keeffe.

The South Charitable Infirmary has the following medical staff.—Physicians: Dr. P. T. O'Sullivan and Dr. N. I. Townsend. Surgeons: Dr. H. R. Townsend, Dr. H. Corby, and Dr. T. G. Atkins. Ophthalmic Surgeon: Dr. A. W. Sandford. Extern Physician: Dr. D. J. O'Flynn. Extern Surgeon: Dr. R. P. Crosbie. House Surgeon: Dr. E. V. Cantillon. Dentist: Mr T. C Butterfield.

HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

ADELAIDE MEDICAL AND SURGICAL HOSPITALS, Peter-street. Dublin.—Fee for nine months' hospital attendance, £12 12*s*.; six months, £8 8*s*. Summer, three months, £5 5*s*.

Staff.—Physicians: James Little, M.D., M.R.I.A.; Wallace Beatty, M.D., F.R.C.P.I.; H. T. Bewley, M.D., F.R.C.P.I. Surgeons: F. T. Heuston, M.D., F.R.C.S.I.; T. E Gordon, M.B., F.R.C S.I. Obstetric Surgeon: W. J. Smyly, M.D., F.R.C.P I. Ophthalmic Surgeon: H. R. Swanzy, M.B., F.R C.S.I. Throat Surgeon: S Horace Law, M.D., F.R C.S.I. Pathologist and Bacteriologist: J. Alfred Scott, M.D. F R.C.S.I. Assistant Physician: G. Peacocke, M.D., F.R.C.P. Assistant Surgeon: K. E. Levison-Gower Gunn, M.D., F.R.C.S. House Surgeon: O. R Millar, M.B., B.Ch.

A resident surgeon is elected yearly and three resident pupils half yearly. At the termination of the session prizes in Clinical Medicine and Surgery and in Obstetric Medicine will be awarded.

Hudson Scholar, 1901, Ernest Henley.

Hudson Scholarship.—In addition to the junior prizes, the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in Clinical Medicine and Medical Pathology, Clinical Surgery and Surgical Pathology, Pathological Histology, Surgical Appliances, including instruments and bandaging, Ophthalmology and Gynæcology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Further particulars may be obtained from Mr. F. T. Heuston.

COOMBE LYING-IN HOSPITAL AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN, Dublin.—This hospital contains nearly 70 beds and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of the diseases peculiar to women. The maternity department is one of the largest in Ireland, 3000 cases being annually treated either as intern or extern patients. A regular course of lectures is delivered in the hospital, and clinical instruction is given daily at the bedside There are two large dispensaries connected with the institution, at one of which instruction is given on the General Diseases of Women and Children, and in the other on the Diseases Peculiar to Women. There is accommodation for a limited number of intern pupils, who enjoy exceptional advantages of acquiring a practical knowledge of this branch of their profession. Two Resident Pupil Midwifery Assistants and one Clinical Clerk are elected half-yearly from among the pupils of the hospital. Certificates of attendance at this hospital are accepted by all licensing bodies, and the diploma is recognised by the Local Government Board as a full legal midwifery qualification. Fees (six months' course): extern pupils, 8 guineas, half payable in advance; intern pupils, 18 guineas for six months' residence. If pupils enter as interns by the month the fees are £4 4*s*. for first month, and £3 3*s*. for each succeeding month. Intern pupils enjoy very special advantages, which can be learned on application. Registration fee on entrance, 10*s*. 6*d*. Students can enter for attendance at any time. Further particulars may be had on application to the Master or the Registrar at the hospital.

Staff.—Consulting Physicians: Sir John T. Banks, Sir John W. Moore, and Dr. J. M. Redmond. Consulting Surgeons: Dr. F. T. Heuston and Dr. F. W. Kidd. Pathologist: Dr. E. J. McWeeney. Pathological Analyst: Sir C. A. Cameron. Master: Dr. T. G. Stevens. Assistants to the Master: Dr. Thomas Neill and Dr. Trevor N. Smith. Registrar: Fred. A. Heney.

SIR PATRICK DUN'S HOSPITAL.—Fees for attendance of students—nine months, £12 12*s*; winter session, £8 8*s*.; summer session, £5 5*s*. The hospital is open to extern students as well as to the students of Trinity College, and the certificates are recognised by all the licensing bodies in the kingdom. Dr. Taylor, Secretary to the Medical Board, will give any further information.

Staff.—Consulting Physician: Sir John Banks. Physicians: Dr. John Mallet Purser, Dr. Walter George Smith, Dr. John Magee Finny, Dr. Arthur Vernon Macan. Assistant Physician: Dr. Henry C. Drury. Surgeons: Dr. Edward H. Bennett, Dr. Charles B. Ball, Dr. Edward H. Taylor. Pathologist: Dr. Alexander C. O'Sullivan. Assistant Surgeon: Dr. R. H. Kennan. House Surgeon: Dr. C. A. K. Ball.

MERCER'S HOSPITAL.—This hospital, founded in 1707, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and within five minutes' walk of Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of Resident Pupil, &c. There is a large out patient department and a special department for diseases peculiar to women. There are also special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements.

Appointments.—A House Surgeon is appointed annually. Five Resident Pupils, each for six months, and Clinical Clerks and Dressers are appointed monthly from amongst the most deserving members of the class.

Fees.—Winter, six months £8 8*s*; Summer, three months, £5 5*s*.; nine months, £12 12*s*.

For further particulars apply to R. Charles B. Maunsell, M.B., F.R.C.S., [illegible]2, Lower Baggot-street, Dublin.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.—Physicians: Sir John William Moore, Dr. James Craig, and Dr. Edward E. Lennon. Surgeons: Sir Philip Smyly (Surgeon to the King), Mr. L. H. Ormsby (Vice-President of the Royal College of Surgeons in Ireland), Mr. W. J. Hepburn, Mr. William Taylor, and Mr. Lane Joynt. This hospital was founded in 1753 and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers has recently been added. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Six Medical and Twelve Surgical Resident Pupils and Clinical Clerks and Dressers are appointed every six months, and a House Surgeon is elected annually. The session will open on Oct. 1st and the opening address will be delivered by Mr. William Taylor on Monday, Oct. 14th. A prospectus giving the complete arrangements for the Medical and Surgical classes for the coming session may be obtained from the Secretary of the Medical Board, R. Lane Joynt, F.R C S, 84, Harcourt-street, Dublin.

MATER MISERICORDIÆ HOSPITAL, Dublin. — Consulting Physician: Sir Francis R. Cruise Physicians: Sir Christopher Nixon, Dr. Joseph Redmond, Dr. John Murphy, and Dr. Martin Dempsey. Assistant Physician: Dr. John O'Donnell. Surgeons: Messrs. Patrick Hayes, Charles Coppinger, Arthur Chance, and John Lentaigne. Assistant Surgeon: Mr. Alexander Blayney. Obstetric Physician: Dr. Thomas More Madden. Ophthalmic Surgeon: Mr. Louis Werner. Dental Surgeon: Mr. Daniel Corbett, jun. Pathologist: Dr. Edmond McWeeney. Anæsthetist and Surgical Registrar: Dr Michael O'Sullivan. House Physicians: Dr. James Gorman and Dr. Michael Curran. House Surgeons: Mr. M. McDonough, Mr. A. Gill, Mr. A. J. Quirke, and Mr. Alexis J. Fitzgerald. This hospital, the largest in Dublin, at present containing 335 beds, is open at all hours for the reception of accidents and urgent cases. Fifty beds are specially reserved for the reception of patients suffering from fever and other contagious diseases. Instruction at the bedside will be given by the Physicians and Surgeons at 9 A.M. daily. Clinical Instruction will commence on Monday, Oct. 2nd, at 9 A.M. A course of Clinical Instruction on Fever will be given during the winter and summer sessions. A certificate of attendance upon this course, to meet the requirements of the licensing bodies may be obtained. Opportunities are afforded for the study of Diseases of Women in the ward under the care of the Obstetric Physician, and at the Dispensary held on Tuesdays and Saturdays. Ophthalmic Surgery will be taught in the Special Wards and Dispensary. Surgical Operations will be performed on Mondays, Tuesdays, Fridays, and Saturdays at 11 o'clock. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, Accidents, &c Instruction will be given on Pathology and Bacteriology. Junior Appointments: Four House Physicians and eight House Surgeons will be appointed annually. Ten resident pupils will be elected from the most attentive of the class to hold office for six months For the current session the elections will take place in November, 1899, and in May, 1900 Dressers and Clinical Clerks will be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes: One Gold and one Silver Medal will be offered for competition annually in the subject of Medicine, and one Gold and one Silver Medal in the subject of Surgery. Junior Leonard Prizes: One prize value £3 and one prize value £2 will be awarded in Medicine, and one prize value £3 and one prize value £2 will be awarded in Surgery. They will be awarded on the aggregate of marks gained for Reports of Cases and at a Clinical Examination to be held at the close of the summer session. For further particulars see prospectus. Certificates of attendance upon [illegible] the Universities and licen[illegible] Private Wards have been [illegible] and Surgical cases. A Training School and Home for Trained Nurses have been opened in connexion with the Hospital.

Terms of attendance—Nine months, £12 12*s*.; six winter months, £8 8*s*; three summer months, £5 5*s*. Entries can be made with any of the physicians or surgeons, or with the Registrar, Arthur Chance, F.R C S, 90 Merrion square. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes, &c., may be obtained from the Secretary, Dr. Joseph Redmond, 41, Merrion-square, E, Dublin.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, North Brunswick-street, Dublin.—These hospitals contain 312 beds—110 for Surgical cases, 82 for Medical cases, and 120 for Fever and other epidemic Diseases. A Resident Physician and a Resident Surgeon are appointed each year and are paid for their services. Clinical Clerks: Five Resident Clinical Clerks are appointed each half-year, and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced Students as formerly, but also to those who are qualified in Medicine or Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. For prospectuses apply to Sir W. Thomson, F R C S., Treasurer, 54, Stephen's-green East; or to J O'Carroll, M.D., Honorary Secretary, 43, Merrion square, Dublin.

ROTUNDA HOSPITAL, Rutland square, Dublin.—This institution consists of two distinct hospitals—namely, the Lying-in Hospital and the Auxiliary Hospital, the latter for the reception of patients suffering from Uterine and Ovarian Diseases There is a large extern maternity and also a Dispensary for Diseases Peculiar to Women, which is open daily Clinical instruction is given daily (Saturdays excepted) in Midwifery and the Diseases peculiar to Women, special attention being directed to the application of antiseptics in Midwifery. Accommodation is provided for a limited number of intern pupils. Consulting Physician. Dr James Little. Consulting Surgeon: Sir Philip C Smyly. Master: Dr. R. Dancer Purefoy. Assistant Physicians *Dr. H. C Lloyd* and *Dr. P. Carton*. Clinical Clerks: Dr. M. T Goldstine and Dr W. F. Colclough

DR. STEEVENS'S HOSPITAL.—This hospital, containing beds for 200 patients, is situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, occupying a position in the centre of one of the busiest manufacturing districts of the city, otherwise unprovided with medical institutions, and affords exceptional advantages for clinical instruction. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane. The hospital is easily accessible by two lines of tramways. There is a ward entirely devoted to Venereal Disease, a detached building for Fever Cases, and an extensive Out-patient Department, with separate Clinics for Diseases of the Skin, Throat, Eye, Ear, Teeth, and Women. The hospital is visited daily by the physicians and surgeons. The wards are also visited by the resident surgeon each evening. Clinical Lectures are given by the physicians and surgeons during the session. There is accommodation in the hospital for four medical, six surgical, and two special resident clinical assistants.

Fees—Hospital Practice: Nine months, £12 12*s*; six months, £8 8*s*; three months, £5 5*s* Dressership: £10 10*s*, each three months. Further information may be obtained from the Resident Surgeon or from R A. Hayes, M.D., Honorary Secretary, 82, Merrion square South.

PUBLIC HEALTH.

INSTRUCTION FOR DIPLOMAS IN STATE MEDICINE

ENGLAND.

THE following recommendations, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," were adopted by the General Medical Council in 1896.[1] The regulations require that—"(1) A period of not less than twelve months shall elapse between the attainment of a first registrable qualification in Medicine, Surgery, and Midwifery and the examination for a diploma in Sanitary Science, Public Health, or State Medicine; (2) every candidate shall have produced evidence of having attended, after obtaining a registrable qualification, during a period of six months, practical instruction in a laboratory approved of by the body granting the qualification; (3) every candidate shall have produced evidence of having for six months practically studied the duties of outdoor sanitary work either under a *medical officer* of health who is a teacher in public health in a recognised school, or under the medical officer of health of a county or of a single sanitary district of 50,000, or in one or more districts of 30,000 in Scotland or Ireland; (4) the examination shall have been conducted by examiners specially qualified, and shall comprise laboratory work as well as written and oral examination; (5) the rules as to study shall not apply to medical practitioners registered, or entitled to be registered, on or before Jan 1st, 1890." It was enacted by Section 18 (2) of the Local Government Act [England and Wales], 1888, that after Jan. 1st, 1892, no such appointment (that of medical officer of health) may be made in any county, or in any district or combination of districts with a population of 50,000 or upwards, unless the officer—having, of course, qualifications in Medicine, Surgery, and Midwifery—is registered as the holder of a diploma in Sanitary Science, Public Health, or State Medicine under Section 21 of the Medical Act, 1886 or has during any three consecutive years preceding 1892 been medical officer of a district or combination of districts with a population of 20,000 at least, or has for three years previously to August 13th, 1888, been a medical officer or inspector of the Local Government Board. With the sanction of the Local Government Board the same person may be appointed medical officer for two or more districts.

After Christmas, 1901, when the last examination under the above regulations will be held, the conditions will be considerably modified It will then be necessary that a candidate before admission to the examination shall, in addition to the other requirements, "have been for six months associated day by day in the duty, routine and special, of *public health administration under the supervision of a* medical officer of health" who must hold office of a specified nature. The candidate will also be called upon to produce evidence that he has attended for three months the practice of a fever hospital at which opportunities are afforded for the study of methods of administration.

The regulations in question as to study, which may be procured at the office of the General Medical Council in London, shall not apply to medical practitioners registered, or entitled to be *registered, on or before Jan. 1st, 1890.*"

---

[1] The regulations were last settled on June 9th, 1896, and came into operation on Jan 1st, 1897.

London University.—Sanitary Science is included under the head of State Medicine in the M.D. degree, and a certificate has to be produced showing that a course of practical instruction has been attended for the prescribed period, and that the course has included such chemical, microscopical, and meteorological work and exercises as more especially relate to sanitation. The attendance includes six months' practical instruction in a laboratory and six months' outdoor sanitary work. Certificates will be received from the holder of any public health office directly or indirectly subject to control by a Secretary of State or a Government Department. Candidates for the M.D. degree in State Medicine must have (1) studied State Medicine for two years or (2) have studied State Medicine for one year and have held for a period of two years the position of medical officer of health in any sanitary district, or (3) *without having studied State Medicine* have held for a period of three years the position of medical officer of health in any sanitary district.

Cambridge University.—Two examinations in so much of State Medicine as is comprised in the functions of medical officers of health will be held during the year 1900 in Cambridge. Each examination will consist of two parts. Part I. will begin on the first Tuesday in April and October respectively; Part II. will begin on the second Tuesday in April and October respectively; and each part will end on the following Thursday. Any person whose name is on the Medical Register is admissible as a candidate for this examination provided (1) a period of not less than twelve months shall have elapsed between the attainment of registrable qualification and the time when he presents himself for either part of the examination; (2) he produce evidence of having, *after obtaining a registrable qualification*, attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration; (3) he produce evidence of having, *after obtaining a registrable qualification*, attended during a period of six months on one or more courses, approved by the Syndicate, of practical laboratory instruction in Chemistry, Bacteriology, and the Pathology of those diseases of animals that are transmissible *to man*; (4) he produce evidence of having, after obtaining a registrable qualification, for six months (of which at least three months shall be distinct and separate from the period of laboratory instruction) been associated day by day in the duty, routine and special, of public health administration under the supervision of: (*a*) In England and Wales either the medical officer of health of a county or of a single sanitary district having at the date of the last census a population of not less than 50,000 or the medical officer of health of a combination of two or more sanitary districts having collectively at the date of the last census a population of not less than 35,000; or (*b*) in Scotland or Ireland the medical officer of health of a county or of one or more sanitary districts having at the date of the last census a population of not less than 30,000; or (*c*) a medical officer of health who is a teacher in the department of public health of a recognised medical school. A certificate of an assistant officer of health of a county or a large urban district may be accepted, provided the medical officer of health of a county or district consents to the assistant officer giving such instruction. Any candidate who shall produce evidence that he has himself held an appointment as medical officer of health under conditions not requiring the possession of a special sanitary diploma shall be exempt from this regulation. The provisions as to previous study shall not apply to medical practitioners registered, or entitled to be registered, on or before Jan. 1st, 1890. The first part of the examination will have reference to the general principles of sanitary science and will comprise the following subjects. The elements of chemistry and physics: methods of chemical analysis and in particular the analysis of air and water. The laws of heat and the elements of pneumatics, hydrostatics, and hydraulics in their application to warming, ventilation, water-supply, and drainage. The geological and other conditions determining the healthiness of sites for dwellings. Sources, storage, and purification of water-supply. The elements of meteorology in relation to health. Principles of building construction in their application to dwellings, hospitals, and schools. The disposal of sewage and refuse and the general principles of sanitary engineering. Disinfectants, their chemistry and use. The chemical and microscopical examination of foods and the detection of the commoner for [illegible]. The methods of bacteriological [illegible]. The bacteriology of air, water, [illegible] general pathology of infection, and of the diseases of animals that are transmissible to man. The second part of the examination will have reference to State Medicine and to the applications of Pathology and Sanitary Science, and will comprise the following subjects. Laws and Statutes relating to Public Health.[1] The model by-laws of the Local Government Board. Sanitation of dwellings, schools, factories, and workshops, and of villages and towns. Inspection of slaughter-houses, cowsheds, &c. Inspection of meat and other articles of food. General epidemiology, with special reference to the origin, pathology, symptoms, propagation, geographical distribution and prevention of the epidemic, endemic, and other infective diseases both of temperate and of tropical climates. The methods applicable to the medical investigation of epidemics. Effects on health of overcrowding, vitiated air, impure water, polluted soils, and bad or insufficient food. Unwholesome trades and occupations, and the diseases to which they have rise. Nuisances injurious or dangerous to health. The effects on health of season and climate. The principles and methods of vital statistics in relation to public health. (N.B.—The foregoing schedule is not to be understood as limiting the scope of the examination, which will include every branch of sanitary science. No candidate will be approved by the examiners who does not show a high proficiency in all the branches of study, scientific and practical, which bear upon the duties of medical officers of health.) The examination in both parts will be oral and practical, as well as in writing. One day at least will be devoted to practical laboratory work and one day to oral and practical examination in, and reporting on, subjects connected with outdoor sanitary work. Candidates may present themselves for either part separately or for both together at their option; but the result of the examination in the case of any candidate will not be published until he has passed to the satisfaction of the examiners in both parts. Every candidate will be required to pay a fee of £6 6*s.* before admission or re-admission to *either part* of the examination, but candidates who have presented themselves before the year 1896 will be re-admitted to either part on payment of a fee of £5 5*s.* Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a diploma testifying to his competent knowledge of what is required for the duties of a medical officer of health. All applications for information respecting this examination should be addressed to Dr. Anningson, Walt-ham-sal, Barton-road, Cambridge, Secretary to the Syndicate. Candidates who desire to present themselves for the examination must send in their applications on forms supplied for the purpose and transmit them with the fees to J. W. Clark, M.A., Registrary, University of Cambridge, for the April examination on or before March 17th and for the October examination on or before Sept. 15th. The prescribed certificates must be sent to the Registrary so as to reach him not later than 10 A.M. on March 29th and Sept 27th respectively. Cheques should be crossed "Barclay and Co., Ltd." The fee for either part of the examination cannot be returned to any candidate who fails to present himself; but he will be entitled, without an additional fee, to be a candidate on one subsequent occasion. Candidates must before admission to either part of the examination produce evidence of having satisfied provisions (1), (2), and (3), and before admission to Part II. having satisfied provisions (4), above mentioned. The following is a list of colleges and schools of medicine at which the courses of laboratory instruction have, for the purposes of this examination, been already approved by the State Medicine Syndicate: The Chemical and Pathological Laboratories, Cambridge; the London Hospital Medical College; St. Bartholomew's Hospital Medical College; King's College, London; University College, London; the Army Medical School, Netley; Owens College, Manchester; the University of Durham Medical School, Newcastle-on-Tyne; Mason College, Birmingham; University College and Southern Hospital School, Liverpool; St. Mary's Hospital Medical

---

[1] All candidates will be examined in the provisions of the English Statutes relating to public health, but any candidate will be given an opportunity of showing a special knowledge of other sanitary laws in operation within the British Empire, provided that, *when applying for admission to the examination, he give notice* of his desire and indicate the special law he proposes to offer.

College; Charing-cross Hospital College; Westminster Hospital Medical School; University College, Bristol; Yorkshire College, Leeds; Guy's Hospital Medical School; St. Mungo's College, Glasgow; Edinburgh University Public Health Laboratory; Middlesex Hospital Medical School; Royal Southern Hospital, Liverpool; Royal Colleges, Edinburgh; Surgeons' Hall, Edinburgh; British Institute of Preventive Medicine; Trinity College, Dublin; Queen's College, Belfast; St. Thomas's Hospital Medical School; University College, Cardiff; and University College, Sheffield.

University of Oxford (Diploma in Public Health).—An examination, open to all registered medical practitioners, conducted partly in writing, partly *vivâ voce*, and in each subject partly practical, is held in Michaelmas Term in the following subjects:—General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The fee for admission to the examination is £10. For further information application should be made to the Secretary to the Boards of Faculties.

University of Durham.—Sanitary Science is the special object of the degrees in Hygiene. Candidates for the degree of Bachelor in Hygiene (B. Hy.) must be at least twenty-two years of age and registered, and before presenting themselves for examination must have been for at least twelve months graduates in Medicine of a recognised university. They shall spend six months at Newcastle-upon-Tyne studying Public Health, Comparative Pathology, Practical Bacteriology, Outdoor Sanitary Work, Infectious Diseases, Sanitary Chemistry; and Physics. They have to pass an examination in Sanitary Chemistry, Physics, Comparative Pathology, Sanitary Legislation, Vital Statistics, Nosology, Climatology, Meteorology, Distribution of Health and Disease, Sanitary Medicine and Practical Hygiene. The fee for the examination for the degree of B.Hy. is 10 guineas, and for the degree £6 6s. The examination is divided into two parts and candidates may present themselves for either part or both together at their option. Candidates for the degree of Doctor in Hygiene (D.Hy.) must have acquired the degree of Bachelor in Hygiene, must for two years subsequently have been engaged in practice as a medical officer of health and must write an essay upon some practical hygienic subject. The fee for the examination for the degree of D.Hy. is £5, and for the degree £6 6s. The regulations for education and examination for the Diploma in Public Health (D.P.H.) are the same as those for the degree of Bachelor of Hygiene except that the candidate is not required to be a graduate in Medicine of a recognised University, and the course of study need not be passed at Newcastle-upon-Tyne. The fee for the examination and Diploma in Public Health is ten guineas.

Victoria University.—An examination in Public Health is held yearly under the following regulations: The examination is in two parts, and is written, oral, and practical. Candidates before entering for either part of the examination must have held for not less than twelve months a registrable qualification in Medicine, Surgery, and Midwifery, and must present satisfactory certificates of having attended courses of instruction in Public Health in a college of the University, or in a college or medical school recognised for this purpose by the University; of having attended, after obtaining a registrable [illegible] nstruc- [illegible] courses [illegible] cteriolo- [illegible] which [illegible] tended for three months the clinical practice of a hospital for infectious diseases; of having practically studied the duties of outdoor sanitary work for not less than six months under the medical officer of health of a county or of a large urban district. Candidates may present themselves for Parts I. and II. separately or at the same time, provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination. The fee for each part is £5 5s., and must be paid on or before July 1st in each year. For any subsequent examination in the same part the fee will be £3 3s. Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health. The examinations will begin on the third Monday in July each year.

Royal College of Physicians of London and the Royal College of Surgeons of England.—The following are the regulations for obtaining the Diploma in Public Health:—Section 1: Candidates must be registered under the Medical Act. The examination consists of two parts. The fee for each part is £5 5s. A candidate intending to present himself must give fourteen days' written notice to the Secretary, at the Examination Hall, Thames Embankment, W.C. A candidate registered under the Medical Act on or before Jan. 1st, 1890, will be admissible to Part I. of the examination on producing evidence of being at least twenty-three years of age, and to Part II. on producing evidence of being at least twenty-four years of age. A candidate registered under the Medical Act after Jan. 1st, 1890, will be admissible to examination in Part I. on producing evidence (1) of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery for at least twelve months; (2) of having attended, after obtaining such registrable qualification, practical instruction in a laboratory recognised by the Examining Board in England during a period of six months; and (3) of being at least twenty-three years of age. A candidate will be admitted to Part II. of the examination on producing evidence (1) of having been associated day by day in the duty, routine and special, of Public Health administration during six months (of which at least three months shall be distinct and separate from the period of laboratory instruction required under Para. 2 for Part I.) under the supervision of a medical officer of health who fulfils certain conditions which can be ascertained on application to the secretary; (2) of having attended the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England, after obtaining his registrable qualification in Medicine, Surgery, and Midwifery; and (3) of being at least twenty-four years of age.

King's College, London.—The necessary Laboratory Instruction to comply with the regulations of the various Universities and other Medical Licensing Bodies will be given by Professor William R. Smith, M.D., D.Sc., and Professor Hewlett, M.D. Lond. The syllabus includes Physics, Chemistry, Microscopy; Parasites and other Organisms Infesting Food-stuff or the Human Body; Bacteriology, including the Cultivation and Recognition of Micro-organisms. The course will last six months, four months of which will be spent in the Laboratories of Public Health, and two months in the Bacteriological Laboratory. Fee 20 guineas, payable in advance in the College office. Under the direction of Professor William R. Smith, M.D., D.Sc., and Demonstrator E. Russell, B.Sc., F.C.S., practical instruction will be given in the laboratories in the methods of Analysis of Air, Water, Foods, &c.; Detection of Poisons. Fees, one month, £4 4s.; three months, £10 10s. The laboratories are also available for original investigations and practical work in Public Health, and are open daily from 9 A.M. to 4 P.M. and on Saturdays to 1 P.M. In Public Health special classes will be held during the winter session by Professor W. R. Smith; fee, £12 12s. The Bacteriological Laboratory is open daily for original research under the direction of the professor and demonstrator of General Pathology and Bacteriology. For one month for original research, 5 guineas. For a longer period by arrangement. For one month for private study, with supervision, 5 guineas. For a longer period by arrangement. Practical course for a month, with attendance on lectures, 5 guineas. For a year, 30 guineas. Professor H. G. Seeley, F.R.S., will deliver a course of six lectures on Physiography.

University College, Bristol.—A course of lectures on the Principles and Practice of Hygiene is given at the College by D. S. Davies, M.D. Lond., D.P.H. Cantab., on Mondays and Fridays, 10-11 A.M., commencing on the first Monday in October. A six months' course of Practical Laboratory Instruction is given at the Western Counties' Laboratory, Park-street, by Mr. F. Wallis Stoddart, commencing on the first Wednesday in October, and including the subjects of Chemistry and Physics. Instruction in Bacteriology is given at the College by Professor A. F. Stanley Kent, M.A., F.L.S., F.G.S. Demonstrations on the provisions and practical working of the various Acts relating to Public Health and on the Orders, Circulars, and By-laws of the Local Government

Board are delivered by Mr. J C Heaven on Mondays and Fridays, commencing on the first Monday in October. Gentlemen taking out the course are admitted to practical outdoor sanitary work during the session, under the supervision of the medical officer of health for the city and port of Bristol. They are considered as pupil assistants and are required to carry out diligently such of the duties of medical officers of health as they may be directed to undertake. Facilities are afforded during the course for the study of those diseases of the lower animals which are communicable to man. Fee for the entire course, 30 guineas.

University of Birmingham.—The University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions: Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health, by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University and they must, in addition, have attended a three months' course of Geology in the University. The following are the regulations for Diploma in Public Health (general conditions):—1. All candidates must be registered under the Medical Act. 2. The examinations will be held in the months of January and June, and will consist of two parts. No candidate will be allowed to pass Part II. until he has passed Part I. 3. Candidates may enter for Parts I. and II. separately or at the same time. 4. The examination in each part will be written, oral and practical. 5. Candidates intending to present themselves for either part of the examination must give 14 days' notice in writing to the registrar of the University. 6. The fee for each part of the examination is £5. The conditions of admission to the examinations are as follows:—I.—For candidates registered under the Medical Act on or before Jan. 1st, 1890. Candidates so registered will be allowed to sit for examination on producing certificate of registration. II.—For candidates registered under the Medical Act after Jan. 1st, 1890. Candidates will be admitted to examination on producing evidence: (1) of being at least 23 years of age, and of having been possessed of a registrable qualification in Medicine, Surgery, and Midwifery, for a period of 12 months; (2) of having received, after obtaining a registrable qualification, during six months, practical instruction in a Laboratory or Laboratories, British or Foreign, approved by the University, in which Chemistry, Bacteriology, and the Pathology of the Diseases of Animals transmissible to Man are taught; (3) that, after obtaining a registrable qualification, he has, during six months (of which at least three months shall be distinct and separate from the period of laboratory instruction required under Rule 2) been associated day by day in the duty, routine and special, of public health administration under the supervision of: (*a*) in England and Wales, the medical officer of health of a county or of a single sanitary district having a population of not less than 50,000, or a medical officer of health devoting his whole time to public health work; or (*b*) in Scotland, a medical officer of health of a county or counties, or of one or more sanitary districts having a population of not less than 30 000; or (*c*) in Ireland, a medical superintendent officer of health of a district or districts having a population of not less than 30,000; or (*d*) a medical officer of health who is also a teacher in the department of Public Health of a recognised medical school (the certificate of an assistant medical officer of health of a county or of a single sanitary district having a population of not less than 50,000 may be accepted as evidence under Rule 3, provided the medical officer of health of the county or district in question permits the assistant officer to give the necessary instruction and to issue certificates); and (4) that after obtaining a registrable qualification he has attended during three months the practice of a hospital for infectious diseases, recognised by the University, at which opportunities are afforded for the study of method of administration.

SCOTLAND.

Edinburgh University.—Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh, viz., Bachelor of Science in Public Health and Doctor of Science in Public Health. Candidates for the degree of B.Sc. in Public Health must be graduates in Medicine of a University of the United Kingdom, or of some other University recognised for the purpose, and must pass two examinations, for the first of which they must, after graduation in Medicine, have worked for at least twenty hours per week during a period of not less than eight months, of which at least five consecutive months must be in the Public Health Laboratory of the University of Edinburgh and the remainder either there or in a laboratory recognised by that University; they must also have attended lectures on Physics and Geology in some Scottish University. Candidates are not admitted to the Second Examination sooner than six months after having passed the First Examination, nor sooner than eighteen months after having taken their degree in Medicine, and they must have attended two separate courses in Public Health in some University of the United Kingdom or in such medical school or Indian, Colonial, or Foreign University as may be approved for the purpose by Edinburgh University, each course consisting of forty lectures at least; one of these courses shall deal with medicine and the other with engineering, each in its relation to public health. They must also give evidence (1) that for six months they have practically studied sanitary work under the medical officer of health of a county or borough or district containing a population of not less than 25,000; (2) that they have had three months' clinical instruction regarding fevers and infectious diseases; and (3) that they have had three months' instruction in mensuration and drawing. The subjects of examination include Laboratory work, Physics, Geology, Medicine in its application to Public Health, Sanitation, Sanitary Law, and Vital Statistics. Graduates who have held the degree of B.Sc. in Public Health from the University of Edinburgh for a term of five years may offer themselves for the degree of D.Sc. in Public Health in that University. They must then present a Thesis and pass an examination in Public Health. The fees are £3 3*s.* for the First and £3 3*s.* for the Second B.Sc. Examinations, and £10 10*s* for the degree of D.Sc.

University of Aberdeen.—The Diploma in Public Health (D.P.H.) is conferred only on graduates in Medicine of a University in the United Kingdom; and a period of not less than twelve months must elapse between medical graduation and entrance to the examination for the diploma. Every candidate must produce evidence of having attended, after graduation in Medicine, during a period of six months, practical instruction in Hygiene and Bacteriology in laboratories approved of by the University, together with having for a like period after graduation practically and daily studied the duties of outdoor sanitary work under the medical officer of health of a county or large urban district, or of having himself held appointment as medical officer of health. He must also have regularly attended for six months the wards of a general fever hospital containing not less than fifty beds. Every candidate who is not a graduate in Medicine of this University must have attended a course of instruction in the University in one or more of the subjects embraced in the examination for the diploma. The diploma is conferred after an examination in Public Health held in March and July of each year. Candidates desiring to appear for examination at either of these periods must send in their names, with the necessary fee, to the Secretary of the Medical Faculty a fortnight before the examination. The fee is £5 5*s.* The examination is conducted by specially qualified examiners appointed by the University. Candidates may enter for the whole examination at one period or they may enter for Part I. at one period and for Part II. at another and subsequent period.

The Royal Colleges of Surgeons and Physicians of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow.—All candidates for the Diploma in Public Health must have been qualified for at least one year. Those qualified before 1890 and also those who have held the position of medical officer of health to a county or to an urban district of more than 20,000 inhabitants, or an entire rural sanitary district, do not require to produce evidence of attendance on any special courses. All other candidates must have attended, after qualifying, six months' practical instruction in a recognised public health laboratory or laboratories, and must have studied for six months the duties of outdoor sanitary work under the medical officer of health of a county or large urban district, or must themselves have held an appointment as medical officer of health under conditions not requiring the possession of a sanitary diploma. It is also recommended where possible to take out a course of instruction in the diseases of animals transmissible to man. There are two examinations, and candidates may enter for both at one period or for either separately. The First Examination includes (*a*) Laboratory Work (Chemistry and Bacteriology), (*b*) Physics, and (*c*) Meteorology; and the Second Examination embraces (*a*) Report on Premises visited, (*b*) Examination at Fever Hospital, (*c*) Examination at Public Abattoir, (*d*) Written and Oral Examinations on Epidemiology and Endemiology, (*e*) Vital Statistics and Sanitary Law, and (*f*) Practical Sanitation. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of £3 3*s*. is payable by rejected candidates for either examination. The examination is held twice yearly in May and October. The published regulations provide detailed synopses of the subjects of examination and give lists of books from which to select. The Registrar for Edinburgh is Mr. James Robertson, solicitor, 54, George-square, and for Glasgow Mr. Alexander Duncan, LL.D., 242, St. Vincent-street.

IRELAND.

Royal University of Ireland.—This University grants a Diploma in Sanitary Science. It is conferred only on graduates in Medicine of the University. Candidates are not admitted to this examination until the lapse of twelve months from the time of obtaining the first registrable qualification; they must give notice in writing to the Secretaries of their intention to present themselves and must pay the fee, £2 at least one month previously to the examination. Candidates are required to produce a certificate of having, *after obtaining the degree of M.B., B Ch., B.A.O.*, attended six months' practical instruction in a laboratory approved by the University, and also of having for six months practically studied the duties of outdoor sanitary work under the Medical Officer of Health of a county or large urban district. Candidates at this examination must answer in the following subjects. (1) Physics, (2) Climatology, (3) Chemistry, (4), Microscopy, (5) Bacteriology, (6) Geology, (7) Sanitary Engineering, and (8) Hygiene, Sanitary Law, and Vital Statistics.

University of Dublin.—The Diploma in Public Health is conferred, after examination, on the following conditions:—The candidate must be a Doctor in Medicine or a graduate in Medicine and Surgery of Dublin, Oxford, or Cambridge. The name of the candidate must have been on the Medical Register at least twelve months before the examination. The candidate must have completed (unless registered as a practitioner on or before Jan. 1st, 1890), subsequently to registration, six months' practical instruction in a laboratory approved by the University and also have studied practically outdoor sanitary work for six months, under an approved officer of health. The subjects of examination will be:—Part I: Chemistry, Bacteriology, and Hygiene, Pathology (including methods of post-mortem examinations), Physics, and Meteorology. Part II.: Hygiene and Epidemiology, Vital Statistics, Public Health Acts, Sanitary Engineering, and Reports.

Royal College of Physicians and Royal College of Surgeons in Ireland.—Stated examinations for the Diploma in Public Health are held in the months of February, May, and November. A special examination for the diploma can be (except during the months of August and September) obtained on payment of £10 10*s*., in addition to the ordinary fees mentioned below, and on giving notice at least one fortnight before the date of the proposed examination Every candidate for the Diploma in State Medicine must be a registered medical practitioner. (Candidates registered or entitled to be registered prior to January, 1890, are exempt from the rules as to study.) He must subsequently to qualification (1) receive six months' laboratory instruction in Chemistry, Bacteriology, and the Diseases of Animals transmissible to man; and (2) during six months either practically study outdoor sanitary work under a medical officer of health or himself hold an appointment of medical officer of health under conditions not requiring the possession of a special sanitary diploma and shall as an additional requirement attend a hospital for infectious diseases, unless this has been already done during his ordinary medical course. Candidates are examined on four days commencing on the first Tuesday of February, May, and November, Each candidate must return his name to the secretary of the Committee of Management under the Conjoint Scheme three weeks before the examination, and lodge with him a testimonial of character from a Fellow of either of the Colleges, or of the Royal Colleges of Physicians or Surgeons of London or Edinburgh. The fee for the examination is £10 10*s* The examination for the diploma in State Medicine comprises the following subjects:—State Medicine and Hygiene, Chemistry, Meteorology and Climatology, Engineering, Vital Statistics, Law and Bacteriology. For further particulars apply to the Secretary, Committee of Management; Office, Royal College of Physicians, Dublin.

DENTAL SURGERY.

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without the special licence; but it is of eminent advantage to take the L.D S., otherwise few dental appointments at general or special hospitals or dispensaries are available, and, what is still more important, the manual dexterity and knowledge of mechanics requisite for the successful practice of dentistry can only be gained by long and careful training at the dental operating chair and in the dental laboratory; and, this having been attained, it costs but little trouble to pass the special examinations. The subjects beyond those included in the general qualification are—Dental Anatomy and Physiology (Human and Comparative), one course; a separate course of Dental Histology, including the preparation of microscopical sections; Dental Surgery, one course; a separate course of Practical Dental Surgery; a course of not less than five lectures on the Surgery of the Mouth; Dental Mechanics, one course; a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns, Dental Metallurgy, one course; a course of Practical Dental Metallurgy; Practice of Dental Surgery at a recognised school, two years, and a certificate of having been engaged during a period of not less than three years in acquiring a knowledge of Dental Mechanics (this may be obtained by apprenticeship to a duly qualified dental practitioner or in the mechanical department of a recognised dental hospital). In the case of qualified surgeons two years will suffice. The Dental Schools in London are the Dental Hospital of London, the National Dental Hospital and College, and Guy's Hospital Dental School. Most of the large provincial towns have now dental hospitals A convenient arrangement by which, the M.R.C S., L.R C.P., and L.D.S. can be taken is as follows:—The Preliminary Examination in General Education having been passed the student should become apprenticed to a qualified dentist and register as a dental and medical student. (This instruction, however, may be taken prior to the date of registration as a dental student.) During his apprenticeship the student should receive instruction in Chemistry and Physics, Pharmacy and Elementary Biology, and pass in these subjects before entering the hospital. (The foregoing constitute the First Examination.) Having entered the hospital the student should attend the dental and general courses contemporaneously, and pass at the end of the second winter the Second Examination—namely, Anatomy and Physiology. At the completion of his second year of study the Dental Examination should be passed. The student should then devote his time to general studies and pass the Third Examination. When time permits it is advisable to attend the general hospital only until after the First and Second Examinations have been passed. At this point a break may be made to admit of the completion of the dental curriculum and the passing of the examinations for the L.D.S. diploma The best course, however, is to entirely finish the curriculum for the M.R.C.S. and L R.C.P. and then take the special Dental work. The regulations for the Dental Licence of the Royal Colleges of Ireland and Edinburgh and of the Faculty of Physicians and Surgeons of Glasgow are very similar to those of the English College. The L.D.S. can also be obtained alone.

REGISTRATION OF DENTAL STUDENTS.

The registration of dental students is carried on at the Medical Council Office in London in the same manner as the existing registration of medical students, and subject to the same regulations as regards Preliminary Examinations. Students who commenced their professional education by apprenticeship to dentists entitled to be registered or by attendance upon professional lectures before July 22nd, 1878 (when dental education became compulsory), are not required to produce evidence of having passed a Preliminary Examination. Candidates for a diploma in Dental Surgery must produce certificates of having been engaged during four years in professional studies and of having received three years' instruction in mechanical dentistry from a registered practitioner. One year's *bonâ fide* apprenticeship with a registered dental practitioner, after being registered as a dental student, may be counted as part of the four years of professional study. The three years of instruction in mechanical dentistry, or any part of them, may be taken by the dental student either before or after his registration as a student, but no year of such mechanical instruction will be counted as one of the four years of professional study unless taken after registration.

It is now necessary for anyone practising Dental Surgery in this country to register and no foreign qualifications are admitted. Formerly exception was made with regard to the Universities of Harvard and Michigan.

The Royal College of Surgeons of England grants a diploma in Dental Surgery under the following regulations, which apply to all candidates who have registered as dental students after Jan. 1st, 1897 Candidates are required to pass three examinations: the Preliminary Science Examination, the First Professional Examination, and the Second Professional Examination. I. Preliminary Science Examination.—Before admission to this examination the candidate must produce a certificate of having received instruction (which may be taken prior to the date of registration as a dental student) at a recognised institution in Chemistry, Physics, and Practical Chemistry. The examination consists of these subjects and is identical with Part I. of the First Examination of the Examining Board in England. II. The First Professional Examination.—The candidate must produce the following certificates: 1. Of having been engaged during a period of not less than three years in acquiring a practical familiarity with the details of mechanical dentistry, under the instruction (which may be taken prior to registration as a dental student) of a competent practitioner or under the direction of the superintendent of the mechanical department of a recognised dental hospital. In the case of qualified surgeons evidence of a period of not less than two, instead of three, years of such instruction will be sufficient. 2. Of registration as a dental student by the General Medical Council. 3 Of having attended at a recognised Dental Hospital and School (*a*) a course of lectures on Dental Metallurgy; (*b*) a course of Practical Dental Metallurgy; (*c*) a course of Lectures on Dental Mechanics; and (*d*) a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns. Candidates may present themselves for the First Professional Examination after the completion of six months' attendance at a recognised Dental Hospital and School. The Examination consists of Mechanical Dentistry and Dental Metallurgy; the examination in Dental Metallurgy will be by written paper. III. The Second Professional Examination.—The candidate must produce the following certificates: 1. Of having been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a dental student. 2. Of having attended at a recognised dental hospital and school (*a*) a course of Dental Anatomy and Physiology; (*b*) a separate course of Dental Histology, including the preparation of microscopical sections; (*c*) a course of Dental Surgery; (*d*) a separate course of Practical Dental Surgery; (*e*) a course of not less than five lectures on the Surgery of the Mouth, which lectures may be given at a dental hospital or at a recognised medical school; in the latter case they may form part of the course of lectures on Surgery; (*f*) a course of Dental Materia Medica; and (*g*) a course of Dental Bacteriology; (*f*) and (*g*) will only be required of candidates who enter at a Dental Hospital on or after May 1st, 1902. 3 Of having attended at a recognised dental hospital or in the dental department of a recogised general hospital the practice of Dental Surgery during two years. 4. Of having attended at a recognised medical school (*a*) a course of lectures on Anatomy, (*b*) a course of lectures on Physiology, (*c*) a separate Practical Course of Physiology, (*d*) a course of lectures on Surgery, and (*e*) a course of lectures on Medicine. 5. Of having performed Dissections at a recognised medical school during not less than twelve months. 6. Of having attended at a recognised hospital the practice of Surgery and Clinical Lectures on Surgery during two winter sessions. 7. Of being twenty-one years of age. The certificates of professional study will be required to show that students have attended the courses of professional study to the satisfaction of their teachers. Candidates may present themselves for the Second Professional Examination after the completion of four years' professional study from the date of registration as a dental student and after the lapse of not less than six months from the date of passing the First Professional Examination. The Second Professional Examination consists of: Part I., General Anatomy and Physiology, General Surgery and Pathology; Part II., Dental Anatomy and Physiology, Dental Pathology and Surgery, and Practical Dental Surgery. The written examination in Part I. comprises General Anatomy and Physiology, General Pathology and Surgery, and in Part II. Dental Anatomy and Physiology, and Dental Pathology and Surgery. At the Practical Examination candidates may be examined (*a*) on the treatment of Dental Caries, and may be required to prepare and fill cavities with gold or plastic filling or material, or to do any other operation in Dental Surgery (candidates must provide their own instruments); (*b*) on the Mechanical and Surgical Treatment of the various irregularities of Children's Teeth. There is also an Oral Examination. Candidates may take the two parts of the examination together or separately. Exemption from the Preliminary Science Examination is granted to candidates who have passed an Examination in Chemistry and Physics for a degree in Medicine at a University in the United Kingdom, in India, or in a British colony. Exemption from Examination in Anatomy and Physiology is granted to candidates who have passed the Second Examination of the Examining Board in England or the corresponding Examination of the Royal College of Surgeons of Edinburgh, of the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or of any University in the United Kingdom. Exemption from Examination in General Surgery and Pathology is granted to candidates who have passed the Examination in Surgery of the Examining Board in England or the corresponding Examinations of the Colleges and Universities above mentioned. The fee for the diploma is 20 guineas and is payable as follows:—Preliminary Science Examination, 3 guineas; First Professional Examination, 2 guineas; Second Professional examination, 5 guineas; the balance to be paid on the completion of the Examinations. The Preliminary Science Examination is held in January, March or April, July, and October in each year. The First and Second Professional Examinations are held in May and November in each year. Candidates must give twenty-one clear days' notice of their intention to present themselves for examination.

Royal College of Surgeons, Edinburgh.—For the Licence in Dental Surgery all candidates must pass a Preliminary Examination in General Knowledge and have their names inscribed in the Register of Dental Students of the General Medical Council. A copy of regulations, giving a list of Preliminary Examinations recognised for obtaining this Licence, as well as of the subjects of the Professional Examinations, may be obtained from Mr. James Robertson, Clerk to the Royal College of Surgeons, 54, George square, Edinburgh. Students who commenced their professional education by apprenticeship or attendance on lectures before July 22nd 1878 are exempt from the Preliminary Examinations. Candidates must produce certificates of having subsequently to the date of registration, been engaged for four years in professional studies and of three years instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient. Candidates who have commenced their studies *after* Oct. 1st, 1890, must have attended the following curriculum: Anatomy, one course of six months; Practical Anatomy, twelve months; Chemistry, one course of six months; Practical Chemistry, one course of th[illegible] Physiology, one course of six months; [illegible] course of three months; Surgery, one course of six months; Medicine, one course of six months; and attendance on the practice of a recognised general hospital, with Clinical Instruction, twelve months. (Candidates who commenced study in accordance with the regulations in force before July, 1895, shall not be required to attend more than six months' hospital work.) These courses must have been attended at a University or in an established school of medicine or in a provincial school specially recognised by the College as qualifying for the diploma in Surgery. In addition to these courses candidates will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, the following special courses of lectures and instruction: Dental Anatomy and Physiology

(Human and Comparative) (not less than 24 lectures), Dental Surgery and Pathology (not less than 20 lectures), Dental Mechanics (not less than 12 lectures)—one course each; two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College. Certificates of attendance on such of these courses of the new curriculum as may be respectively required will entitle candidates to appear either for the First Dental Examination or for the First and Second Examinations for the Triple Qualification, as they may select and subject to the existing regulations for each qualification. Candidates who have passed the First and Second Examinations for the Triple Qualification will be exempt from the First Dental Examination and will have the advantage of being admissible either to the Final Dental Examination or to the subsequent Examination for the Triple Qualification, or to both. But the First Dental Examination will not be held as equivalent to the First and Second Triple Examinations and will admit to the Final Dental Examination only. Candidates who are Licentiates of this College or who may be registered medical practitioners will be required to produce certificates of attendance on the special subjects only and will be examined in these only for the dental diploma. First Professional Examination: The candidate must have attended the courses on Anatomy, Chemistry, and Physiology. The examination embraces Anatomy, Chemistry and Physiology. The fee for those candidates who began study before Oct 1st, 1896, is £4 4s. Second Examination: The candidate must have attended the remaining courses of the curriculum, must produce certificates showing that he is twenty-one years of age, and must pay a fee of £6 6s. The examination embraces Surgery, Medicine, Therapeutics, and the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, and Dental Mechanics with Dental Metallurgy. Unsuccessful candidates will be repaid £2 2s. in the First and £3 3s. in the Second Examinations. Candidates who claim exemption from the First Dental Examination on the ground of having passed the First and Second Triple Qualification Examinations will, before being admitted to the Second Dental Examination, be required to pay the total fee of £10 10s. payable for the dental diploma, of which £3 3s will be returned in case of rejection. The fee payable by candidates who begun study after Oct. 1st, 1896, shall be £16 16s.

Faculty of Physicians and Surgeons of Glasgow.—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh. Special provision is made for candidates who intend to qualify both in Medicine and in Dentistry. There is a practical examination in Mechanical Dentistry and also an examination in Practical Dentistry conducted in a dental hospital.

Royal College of Surgeons in Ireland.—All information concerning the licence in Dentistry may be obtained from the Registrar of the College, who will receive the applications of candidates for permission to be examined. The bank receipt for fees, together with all certificates, &c., are to be lodged with him at least seven days prior to the day fixed for the commencement of the examination. The Primary Dental Examinations commence on the second Monday in the months of February, May, and November. The Final Dental Examinations commence on the Thursdays immediately following the Primary Dental Examinations. Candidates are required to pass three examinations—viz., Preliminary (in General Education), Primary Dental, and Final Dental. Preliminary Examination.—All examinations in general education recognised by the General Medical Council are accepted by the [illegible]
by th[illegible]
third [illegible]
Exam[illegible]
£5 5s [illegible]
to the Primary Dental Examination, to produce evidence—(1) of having passed a recognised preliminary examination and of having been registered as a medical or dental student by the General Medical Council; (2) of having, subsequently to registration as a dental or medical student, attended at a recognised medical school the following courses: Lectures on Practical Anatomy, including Dental Anatomy, six months; Demonstrations and Dissections two courses of six months each; Lectures on Chemistry six months; Lectures on Physiology, including Dental Physiology, six months; Practical Histology; and Practical Chemistry, including Metallurgy, three months; (3) of having attended Clinical *Instruction at a recognised general hospital for one year.* The subjects of this examination are: (1) Physics;[2] (2) Chemistry, including Metallurgy; (3) Anatomy; (4) Physiology and Histology; and (5) Surgery. Final Examination.—Candidates holding L.R.C.S.I. or students who have passed Primary Dental or Third Professional Examination of the College, £10 10s.; re-examination, £5 5s. Fees for Final Examination of all other candidates, £26 5s.; re-examination, £10 10s. Extra fee for Special Examination, £5 5s. Candidates must produce evidence of having passed the Primary Dental Examination of this College, or the Third Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College, and are required to produce certificates of having attended: (1) the following ([illegible]
Surgery a[illegible]
courses); [illegible]
recognised by the College or of the dental department of a general hospital so recognised; (3) of having been engaged during four years in professional studies; and (4) of having received three years' instruction in Mechanical Dentistry from a registered dentist. Candidates holding a diploma in Surgery shall be admissible to the Final Dental Examination on producing certificates of having attended: (1) one course of Lectures on Dental Surgery and Pathology; (2) one course of Lectures on Dental Mechanics; (3) for one year the practice of a dental hospital recognised by the College, or of the dental department of a general hospital so recognised, where such attendance has been subsequent to the date of diploma (this remission (3) has been made on the understanding that the surgeon devotes his whole time to dental work); and (4) of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist. The following are the subjects of examination: Dental Surgery, Theoretical (including Dental Pathology), Clinical, and Operative; Dental Mechanics, Theoretical, Clinical, and Practical (including the Metallurgy of the Workshop). Examinations for the Licence in Dentistry *sine curriculo:* The Council has power to admit to examination, *sine curriculo*, candidates whose names are on the Dental Register published under the direction of the General Medical Council, and who are unable to furnish the certificates required by the foregoing regulations, on *presentation of a special schedule of application.*

TEACHING INSTITUTIONS.

ENGLAND.

Dental Hospital of London and School of Dental Surgery, Leicester-square.—The school provides the special dental education required by the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 4 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the three years' mechanical training recognised by the curriculum. The demonstrators at the commencement of each session give a course of lectures on Operative Dental Surgery. The eight house surgeoncies are held for one year each, and are open to all qualified students. The lecturers in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the mechanical laboratory. Two scholarships of the value of £20 have been founded by Sir Edwin Saunders and Dr Joseph Walker. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses, at the end of the summer and winter sessions. A prize of the value of 5 guineas is given

---

[1] Candidates educated in England or Scotland are admitted to the Primary Dental Examination on the production of the certificates that would be necessary for both Primary and Final Examinations in their own countries.

[2] Candidates who have passed in Chemistry and Physics at a First Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College, are exempted from examination in these subjects at the Primary Dental Examination.

by Messrs. Ash and Sons for the best essay on some surgical subject connected with Dental Surgery. The conditions under which this prize is to be competed for are the same as those for the Saunders Scholarship, with this exception, that the papers are to be written in the hospital during the summer session. Consulting Physician: Sir Richard Douglas Powell, Bart., M.D. Consulting Surgeon: Mr. Christopher Heath, F R.C S Consulting Dental Surgeons: Mr. T. Arnold Rogers, M.R.C.S., L.D.S., and Mr. Smith Turner, M.R.C.S., L.D.S. Dental Surgeons: Leonard Matheson, L D.S.; E. Lloyd Williams, L.R.C.P., M.R C.S. L.D S., L.S.A.; W. B. Paterson, F R.C.S., L.D.S.; W. H. Woodruff, L.D S; J. F. Colyer, L R.C.P, M.R.C S, L.D.S.; and C F. Rilot, L.R.C.P., M.R.C.S., L.D S. Assistant Dental Surgeons: H Lloyd Williams, M.R.C S., L.D.S.; W. H. Dolamore, L R.C.P, M.R.C.S, L.D.S.; G. Hern, L.R.C.P., M.R C.S., L.D.S.; J. G. Turner, L.R.C.P., F.R.C.S., L.D S; Russell Barrett, L.R.C.P., M R C.S, L.D.S.; N. G. Bennett. M.A., M.B. B.C., L R.C P., M.R.C.S., L.D.S.; D. P. Gabell, L R.C.P., M.R.C.S., L.D.S; and W. J. May, L.R.C.P., M.R.C.S., L.D.S.; A. Hopewell Smith, L.R.C.P., M.R.C.S., L D.S.; W. S. Nowell, M A., L.R.C.P., M.R.C.S., L.D.S.; H. Austen, M.D., L.D.S. Anæsthetists: Dudley W. Buxton, M.D., B.S. Lond., M.R.C.P. Lond.; Carter Braine, F R C.S.; Henry Davis, M.R.C.S., L.S.A.; George Rowell, F R.C.S; and E A. Bridger. M.D. Assistant Anæsthetists: R. Turle Bakewell, M.B. Lond., L.R.C.P., M.R.C S; R. J. Probyn-Williams, M.D. Durh.; George Flux, M D Brux.; H. J. Paterson M.A., M.B, B.C. Cantab., F.R.C.S.; H. Hilliard, L.R C.P., M.R.C.S.; F. H Belfrage, M.D Lond., L.R C.P., M.R.C S. Demonstrators: W. J. Law, L.D.S; R. Pring, L.R.C.P., M.R.C.S., L.D.S.; R. McKay, L.R.C.P., M.R.C S., L.D.S Medical Tutor: Wharburton Brown, L R C P., M.R C.S. Curator of Mechanical Laboratory: W. J. Cave. Lecturers.—Dental Anatomy and Physiology (Human and Comparative): Charles Tomes, F.R.S, M A Oxon., F.R.C.S, L.D.S., assisted by Mr. Hopewell Smith in Dental Histology. Dental Surgery and Pathology: W. Hern, L.R.C.P., M.R.C.S., L.D.S. Mechanical Dentistry: E Lloyd Williams, L R C.P., M.R.C.S. L D.S., L.S A. Metallurgy in its Application to Dental Purposes: Dr. Forster Morley, M.A., F.I C., F C.S., assisted by Mr. H. Richards. During the sessions the surgeons of the day will give demonstrations at stated hours. The house surgeons attend daily while the hospital is open. Fee for two years' hospital practice required by the curriculum, including lectures, £50 in one payment, or 50 guineas in two yearly instalments. The curriculum requires two years to be passed at a General Hospital; the fee for this is about £55 Both hospitals can be attended simultaneously. The fee for three years Mechanical Dentistry is 150 guineas. The Dean, Mr. Morton Smale, attends at the hospital every Wednesday morning from 10 to 12, or he can be seen at other times by appointment. Letters to be addressed—The Dean, 40, Leicester-square, "to be forwarded."

National Dental Hospital and College.—Winter Session, 1901–1902 commences on Oct. 1st at the new building at the corner of Great Portland and Devonshire-streets, W.—Consulting Physician: Sir W. H. Broadbent. Consulting Surgeon: Mr. Christopher Heath. Consulting Dental Surgeon: Mr. S. J. Hutchinson. Visiting Physician: Dr James Maughan Visiting Surgeon: Mr. E. W. Roughton. Dental Surgeons: Mr. F. H Weiss, Mr. A. Smith, Mr. M. Davis, Mr. T. G. Read, Mr. Rushton, and Mr. C. W. Glassington. Assistant Dental Surgeons: Mr. W. Weiss, Mr. E Beverley. Mr. S. F Rose, Mr. A. E. Relph, Dr J. Sims Wallace, and Mr. H J. Relph. Anæsthetists: Mr. H. P. Noble, Mr. C E. A. Macleod, Mr. C J Ogle, Mr. G. E Norton, Dr. J. Maughan, and Mr. F. W. Collingwood. Lecturers (winter), Dental Anatomy and Physiology: Dr J. W. Pare, Tuesdays and Thursdays, 5 P.M., in October, November, and December. Dental Metallurgy: Mr. Hugh Candy. Tuesdays, 5 P M., in January, February, and March. Dental Mechanics: Mr. H. Rose, Wednesdays, 6 P M., in January, February, and March. Dental Materia Medica: Mr. Charles W. Glassington, Tuesdays, 6 P.M, October, November, and December. Summer—Dental Surgery and Pathology, Mr. H. J. Relph, Tuesdays and Fridays, 6 P.M., in May, June, and July. Practical courses to comply with the R.C.S. curriculum are also held. The hospital is lighted throughout by electricity and warmed and ventilated by approved methods. Clinical Lectures and Demonstrations are given from time to time, and each student on entering passes through a preliminary course under a demonstrator. The stopping rooms have accommodation for sixty chairs. Dresserships in the extraction and stopping rooms are re-arranged every three months. An Entrance Exhibition, of the value of £15, is open for competition at the commencement of each summer and winter session. Prizes in medals are open for competition at the end of each course of lectures. Certificates of honour are given in each class. The Rymer Medal for General Proficiency, value £5, is awarded annually to the most meritorious student; and the Ash Prize, value £3 3s., for a Thesis on a subject in Dental Surgery. Total fee for the Special Lectures and Hospital Practice required, 40 guineas. Single Courses: Dental Anatomy and Physiology, Dental Surgery and Pathology, Dental Mechanics, Dental Metallurgy, Dental Materia Medica, Demonstration of Dental Mechanics, £5 5s. each. Hospital Practice to registered practitioners by special permission of Committee, twelve months, £15 15s. The Committee also consider applications from medical men who may desire to attend the Anæsthetic Room for a course of instruction in Nitrous Oxide administration. Information respecting the Hospital Practice and the College may be obtained from the Dean, Mr. Sidney Spokes, who attends at the Hospital, Great Portland-street, on Tuesday mornings.

Guy's Hospital—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. *The Extraction Rooms:* Patients are admitted between 9 and 9.30 A.M., and are seen by the dental surgeon for the day, the dental house surgeon, the assistant dental house surgeon, and the dressers. Such cases as are suitable for conservative treatment are transferred to the conservation room, taking with them a dental chart to indicate the treatment required *The Conservation Room:* This room is open from 9 A M. till 5 P.M. There are 55 Morrison chairs for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. The members of the staff attend every morning and afternoon in the week to give demonstrations and otherwise assist students in their work in the Conservation Room and Mechanical Laboratory. Dental students have the opportunity of attending concurrently at this hospital the two courses of instruction required by the examining board for the L.D.S. Eng., viz., the special lectures and practice of the Dental Department and the general lectures and practice of the Medical School. The fees for these two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge. An Entrance Scholarship in Dental Mechanics of the value of £30 is offered for competition annually in September, and prizes of the aggregate value of £35 are awarded for general proficiency and skill in Practical Dentistry. Dental students are eligible for admission to the Residential College and enjoy the other social privileges of students in the Medical School.

London Hospital.—Mr. Dolamore and Mr. Farmer give practical instruction during the winter and summer sessions on Mondays, Tuesdays, Thursdays, and Fridays at 9 A M. In selecting from candidates for the office of Dental Assistant priority will be given to those who have attended the greatest number of lectures on Dental Pathology and Surgery, and have also been the most punctual in attendance in the dental department. A class for special instruction in filling teeth will be formed each term Candidates for Dressership must undertake to attend regularly on Mondays and Thursdays, or on Tuesdays and Fridays, for three months, and to follow the practical course of demonstrations.

University of Birmingham.—The teaching of Dentistry is undertaken by the University acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board, so that the students may fully qualify themselves for the Dental diploma of the Royal Colleges. There is a special and well-equipped Dental Museum and Laboratory. An Entrance Exhibition, value £37 10s, is awarded annually at the commencement of the winter session. The following are the regulations for Degrees in Dentistry:—1. The degrees conferred by the University are those of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.). 2. All candidates for these degrees must pass the same Matriculation Examination as that required from candidates for Medical Degrees. 3. The degree of Bachelor of Dental Surgery is not conferred upon any candidate who has not obtained a Licence in Dental Surgery from some body legally entitled to confer such qualification. The candidate is not eligible for the degree until a period of 12 months has elapsed from the passing of his examination for the Licence in Dental Surgery. Of this period at least six months must be spent in the dental department of a general hospital approved by the University. 4. *A*. In addition to the Licence in Dental Surgery the candidate must produce evidence that he has attended the Courses required by medical students of the University in the following subjects and passed the Examinations held in the same for Medical and Surgical Degrees: (*a*) Chemistry and Practical Chemistry, (*b*) Physics and Practical Physics, (*c*) Comparative Anatomy, (*d*) Anatomy and Practical Anatomy, and (*e*) Physiology and Practical Physiology. *B*. That he has attended the following Courses: (*f*) One Course of Lectures on Medicine, (*g*) One Course of Lectures on Surgery, (*h*) Special Courses of Lectures on the Surgery and Medicine of the Mouth, and (*i*) Pathology and Bacteriology, and has passed the examinations for candidates for Dental Degrees held in each of these subjects. *C*. That he has attended Courses in: (*k*) Dental Histology and Patho-Histology, (*l*) Comparative Dental Anatomy, and (*m*) Dental Surgery and Prosthetic Dentistry. *D*. That he has received instruction in the Clinical Examination of living cases at the dental department of a general hospital for a period not less than six months. 5. The Final Examination will deal with the subjects in Classes *C*. and *D*. 6. On the expiration of 12 months from the date of passing the Examination for the Degree of Bachelor of Dental Surgery, the candidate will be eligible for that of Master of Dental Surgery. 7. For this degree candidates will be required to submit a thesis containing original work and investigations in some subject connected with Dentistry, which thesis shall be submitted to examiners to be nominated by the Board of Dental Studies. The degree will be awarded or withheld according to the report of these examiners.

University College, Bristol. — Dental students can enter for the full curriculum at Bristol. The Lectures are delivered at the college. Practical instruction is given at the *Royal Infirmary* by Mr. Ackland and at the *General Hospital* by Mr. Genge, both [illegible] Dental Board of the [illegible] Full information may [illegible] Faculty, Professor E. Markham Skerritt, University College, Bristol.

Owens College, Manchester.—Arrangements have been made for dental students to attend the hospital practice at the Manchester Royal Infirmary and the practice at the Victoria Dental Hospital. Lectures on special subjects will be given in the College as follows:—Winter session: Dental Mechanics, Mr. Tanner, Thursday, 4 P.M. Dental Metallurgy, Mr. J. P. Headridge, Monday, at 3.30 P.M. Summer session: Dental Anatomy and Physiology, Dr. Preston, Tuesday at 2 P.M., Friday at 2 P.M. Dental Surgery, Mr. Campion, Tuesday and Friday, 3 P.M. Practical and Operative Dental Surgery, Mr. Whittaker, Wednesday: Lecture, 2.30 P.M.; Demonstration, 4 P.M. Lectures in Dental Histology, Mr. D. Headridge, Monday, at 2 P.M. Fee for each course £4 4*s*. for the Class in Practical Metallurgy, £2 2*s*. Dental practice for two years at the Manchester Royal Infirmary, £10 10*s*.; at the Victoria Dental Hospital at Manchester, £21, paid in advance, or £13 13*s*. for the first year and £8 8*s*. for the second year. At the Victoria Dental Hospital patients attend at 8.30 A.M. daily, and at 6.30 P.M. on Monday, Wednesday, and Friday. Consulting Surgeon: Mr. J. Hardie. Consulting Dental Surgeon: Mr. H. Campion. Dental Surgeons: Mr G. G. Campion, Mr. H H Dreschfeld, Mr. J. W. Dunkerley, Mr. W. Dykes, Mr. W. Headridge, Mr. W. A. Hooton, Mr. P. A. Linnell, Mr. F. W. Minshall, Mr. I. Renshaw, Mr. W. Simms, Mr. C. H. Smale, Mr. T. Tanner, and Mr. G. O. Whittaker. Assistant Dental Surgeons: Mr. J. P. Headridge, Mr. W. H. Norman, and Mr. T. E. Sherratt. Demonstrator: Mr. W. H. Jones. Tutor: Dr. C. H. Preston. Consulting Prosthetic Dental Surgeon: Mr. T. Tanner. House Dental Surgeons: Mr. W. Wright and Mr. H. Hopkinson. Curator of Museum: Mr. D. Headridge. Administrators of Anæsthetics: Dr. A. Wilson, Mr. F. H. Westmacott, and Dr. W. B. Pritchard. Dean: Mr. William Simms.

University College, Liverpool (*Liverpool Dental Hospital and School of Dental Surgery*).—The courses of systematic instruction are given in University College, five minutes from the Dental Hospital. The two institutions are now closely associated and the management of the curriculum is in the hands of a joint committee. At the Dental Hospital recent alterations have been made and as it now stands this school offers advantages to students which are not excelled anywhere. The ground floor of the building contains the following: Extraction-room, with all needful appliances; anæsthetic room, specially reserved with every convenience; and large waiting-room for patients. The first floor has a large board-room and a very comfortable students' room set apart exclusively for the use of students. The whole top floor of the building has been thrown into one fine, airy, and well-ventilated operating room. This room will accommodate upwards of 30 operating chairs, which are of the "Morrison pattern," and each of which has a special electric light (canting pendant) suspended before it. In the basement a very convenient workroom has been fitted up containing the necessary requirements, and there are commodious lavatories for students. A new Laboratory for practical mechanical work was constructed last year, so as to meet the requirements of the curriculum. It is adequately furnished with all the modern appliances of a dental workshop. A skilled Dental Mechanic has been engaged and students are able to undertake at the hospital the whole of their training in Mechanical Dentistry. The times of the lectures at University College are arranged to meet the convenience of students; thus allowing the maximum time for attendance upon Dental Hospital practice. The staff of the hospital includes seven honorary Dental Surgeons, a Demonstrator, two House Surgeons, and a Curator. Fees for two years' hospital practice £21. *Apprenticeship.*—A limited number number of apprentices are admitted annually. Fee for three years £105. Further information may be had from the Warden, Mr. W. H. Gilmour.

The various medical and dental lectures are given at University College. The Anatomical Department contains an excellent collection of skulls illustrative of human and comparative dental anatomy. The dissecting-room and theatre are lighted by electricity. The Physiological and Pathological Departments are housed in new and spacious laboratories erected by the Rev. S. A. Thompson Yates. Fees: The composition fee for all lectures is £50 in one payment on entrance, or in two equal instalments (one-half on entrance and the remainder within twelve months). The fee for general hospital practice is £10 10*s*. Further particulars can be obtained of A. M. Paterson, M.D., Dean.

Devon and Exeter Dental Hospital, Castle-street, Exeter.—Established 1880.—The hospital is open daily (Sundays excepted), and patients are admitted between the hours of 9 and 11 A.M. Students attending the practice of the hospital must consider themselves strictly under the control of the medical officers, and must not undertake any operation without the consent of the dental surgeon for the day. Hon. treasurer, Mr. J. M. Ackland; hon. secretary, Mr. Henry Yeo.

SCOTLAND.

The Incorporated Edinburgh Dental Hospital and School, 31, Chambers-street, Edinburgh.[1]—For the special classes, both theoretical and practical, required by dental students the directors have secured the services of an efficient staff of dental officers and lecturers. There will also be a course of demonstrations in Mechanical Dentistry. Students will receive instruction in Practical Dental Mechanics under the mechanician. The fee for clinics in gold filling is included in the Dental Hospital fee of £15 15*s*. The minimum cost of classes for the whole course of dental instruction amounts to £90 7*s*.

Dental Hospital and School, Glasgow.—The winter session will begin on Oct. 15th and the lectures will be delivered as follows. In Dental Mechanics on Monday evenings, at 7.30 P.M., by Mr. Hugh McKay, L.R.C.S., L.R.C.P. Edin., L.F.P.S., L.D.S., and in Dental Metallurgy on Wednesday evenings at 7.30 P.M., by Professor T. R. Marshall, D.Sc. Ed., F.C.S. Fee for each of the above courses of lectures, £3 3*s*. The lectures and instruction at the Glasgow

---

[1] No returns.

Dental Hospital and School are recognised by all the licensing bodies in the United Kingdom. The fees for two years' hospital practice are £15 15s. Intending students before commencing to attend the lectures or hospital practice must produce evidence of having passed the preliminary examination prescribed by the regulations of the General Medical Council for registration of dental students. The hospital is open daily from 5 to 7 P.M. (Saturdays excepted). Students may enrol either at the beginning of the winter or summer session. Summer session begins April 23rd, 1902.

Glasgow Royal Infirmary (Dental Department).—Mr. W. H. Gray, L.D.S., attends at the Royal Infirmary at 3 P.M. on Mondays, Wednesdays, and Saturdays, and gives a course of instruction in Dental Surgery on these days in summer. The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry with Metallurgy, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Clinical Surgery, six months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital. The attendance on the Dental Clinic is free to students of the hospital; to dental students, one year, £5 5s.; perpetual £10 10s. The winter session opens Thursday, Oct. 17th.

IRELAND.

Royal College of Surgeons in Ireland.—The schools of surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for nearly a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. A refreshment-room is now open where students can have luncheon. There are special rooms set apart for lady students. The entire building is heated by hot-water pipes and lighted throughout by the electric light.

COOKE'S SCHOOL OF ANATOMY, PHYSIOLOGY, AND OPERATIVE SURGERY, London.—The school is prepared to admit to its supplementary work all who may wish to join the same, but in regard to its curriculum work it does not receive more than half-a-dozen students in the course of the year; these have special advantages both as regards Anatomy and Physiology. Charges are but slightly in excess of current charges. Particulars forwarded on application. By decision of the various examining bodies gentlemen rejected at their Anatomical and Physiological Examinations (Second Conjoint, &c.) can get signed up for the supplementary work they are required to put in before re-examination. The school is also recognised for the special dissections for the Fellowship of the Royal College of Surgeons. The operations of surgery are performed on the dead body; such courses are recognised for army promotion and the Royal College of Surgeons. The school possesses a good collection of physiological and chemical apparatus, and gentlemen preparing for the higher examinations receive special instruction in the more difficult subjects.

VOLUNTEER MEDICAL STAFF CORPS (LONDON COMPANIES), Calthorpe-street, Gray's-inn-road, W.C.—Hon. Commandant: Surgeon-General Sir William Guyer Hunter, K.C.M.G., Q.H.S., V.D. Officer Commanding: Surgeon-Lieutenant-Colonel J. E. Squire, V.D. The Volunteer Medical Staff Corps bears the same relation to the Volunteer Army as the Royal Army Medical Corps bears to the regular Army. The course of training has the great advantage of affording, in addition to a knowledge of ordinary military duties, special ambulance instruction useful in all ranks of life. All who have gone through the ranks of this corps are capable of rendering valuable aid in any accident, and in cases of emergency may be the means of saving lives which would otherwise be lost. In addition to the Company and Battalion drills of an ordinary infantry corps, the special training includes stretcher and waggon and cacolet drill; the use of improvised seats and stretchers; the use and application of bandages, splints, &c.; lectures by the officers on first aid to the injured, and on the elements of anatomy, physiology hygiene, and nursing, which are so arranged as not to interfere with the lectures, &c., carried on at the various hospitals in London. There is also a Shooting Club in the corps, in which instruction in, and facilities for, the practice of rifle shooting are given. There is a Transport Section in connexion with the corps, the members of which go through a course of instruction in riding and driving and transport work with the regular troops. There are also sections of Cyclists and Signallers. A Gymnastic Class meets once a week at headquarters, under an instructor who teaches boxing and fencing. Lectures are delivered during the winter session. The headquarters contain a fine drill hall, mess-rooms, canteen, &c., where dinners, suppers, dances, and smoking concerts can be held at any time. The Adjutant, Captain L. Way, R.A.M.C., will give any information respecting the above on application to the headquarters, Calthorpe-street, Gray's-inn-road, W.C.

SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Chemistry and Physics: J. Norman Collie, Ph.D., F.R.S. Botany: Professor Reynolds Green, M.A., Sc.D., F.R.S., F.L.S. (Dean of the school). Pharmaceutics: Professor Greenish, F.I.C., F.L.S. The session commences on Tuesday, Oct. 1st. Medical students, or pupils intending to enter the medical profession, are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in this school are received by the Conjoint Board of the Royal Colleges. Application for admission to the school, or for further information, may be made to the Registrar, 17, Bloomsbury-square, London, W.C.

THE LONDON COLLEGE OF CHEMISTRY, PHARMACY, AND BOTANY, 323, Clapham-road, London, S.W.—Principal, Henry Wootton, B.Sc. Lond. This College, which is established for the purpose of providing thorough and practical instruction in all branches of science, especially for students preparing for Pharmaceutical, Medical, and University Examinations, includes large and completely fitted chemical, pharmaceutical, and physical laboratories, lecture-hall, museum, and class-rooms. Each student has a separate commodious bench, fitted with gas, water, and sink, with large locker for apparatus. There is a botanic garden attached to the school.

WESTMINSTER COLLEGE OF CHEMISTRY AND PHARMACY, LTD., Trinity-square, Borough, S.E.—Principal, G. S. V. Wills, F.L.S. Special instruction given to medical and dental students in chemistry, physics, and pharmacy. Fees and time by arrangement. Ladies are prepared for the Dispenser's Examination of the Apothecaries' Hall. For prospectus, fees, &c., apply to J. E. Walden, Secretary.

ROYAL COLLEGE OF SCIENCE, London (with which is incorporated the ROYAL SCHOOL OF MINES).—Mechanics and Mathematics: Professor J. Perry, F.R.S. Biology: Professor G. B. Howes, F.R.S. (Zoology), and Professor J. B. Farmer, M.A. (Botany). Chemistry: Professor W. A. Tilden, F.R.S., and Dr. W. P. Wynne, F.R.S. Physics: Professor A. W. Rücker, Sec. R.S., and Mr. W. Watson, B.Sc. Astronomical Physics: Professor Sir J. N. Lockyer, K.C.B., F.R.S. Geology: Professor J. W. Judd, C.B., F.R.S., and Dr. Cullis. Metallurgy: Professor Sir W. C. Roberts-Austen, K.C.B., F.R.S. Mining: Professor C. Le Neve Foster, F.R.S. The College re-opens on Wednesday, Oct. 2nd, 1901. Communications should be addressed to the Registrar, Royal College of Science, South Kensington, S.W.

ELECTRICAL STANDARDIZING, TESTING, AND TRAINING INSTITUTION. Faraday House 8 and 10, Charing-cross-road, W.C.—Principal, Hugh Erat Harrison, B.Sc. Lond., F.C.S., A.M.I.C.E., M.I.E.E. Instructor in Mathematics: Alexander Russell, M.A. Glasgow and Cambridge. Instructor in Chemistry: Chas. J. Wilson, F.I.C., F.C.S. Instructor in Mechanical Engineering: Walter H. Bell, A.M.I.C.E. This institution, in addition to its ordinary course of training in electrical engineering, which occupies two or three years, also arranges for special instruction in all branches of electricity either by private tuition or by a specially arranged course at the college or at the works of the companies with which it is associated. There are Entrance Scholarships of the value of 80 and 50 guineas, and Exhibitions of 40 guineas. Particulars may be obtained on application to the Secretary, Howard Foulds, Faraday House, Charing-cross-road, W.C. Session begins Sept. 16th.

OWENS COLLEGE, MANCHESTER	General Entrance Scholarships	—	—	—	Open to candidates above 16 and under 20 years of age.
	Rogers.	£40.	2 years.	Subjects: GREEK, LATIN TRANSLATIONS AT SIGHT, and PROSE COMPOSITION.	
	Seaton.	£40.	2 years.	Subjects: GREEK, LATIN TRANSLATIONS AT SIGHT, and PROSE COMPOSITION.	
	Dalton.	£40.	2 years.	Subjects: EUCLID, ALGEBRA, TRIGONOMETRY, GEOMETRY, and CONIC SECTIONS.	
	Cartwright.*	£35.	3 years.	Ditto	
	Hulme.	£35.	3 years.	Subjects: ENGLISH LANGUAGE and LITERATURE, HISTORY, GEOGRAPHY, and LATIN, GREEK, FRENCH, or GERMAN (any two subjects).	
	James Gaskill.	£40.	2 years.	MATHEMATICS, MECHANICS, and CHEMISTRY.	
	Dora Muir.†	£25.	3 years.	Ditto	
	Manchester Grammar School.*	£18.	3 years.	MATHEMATICS, ENGLISH ESSAY with CLASSICS and PHYSICAL SCIENCE in alternate years.	
	Kay-Shuttleworth.*	£30.	3 years.	Subjects as in James Gaskill Scholarships.	Pupils of Sedbergh, Giggleswick, or Burnley Grammar School.
	Theodores Exhibition.	£15.	1 year.	Subjects: FRENCH and GERMAN	Successful candidates are required to enter for a regular University course
	Robert Platt Physiological Scholarship.	£50.	2 years.	Subjects: PHYSIOLOGY and COMPARATIVE ANATOMY.	Open to Candidates whether or not previously students of the College.
	Dauntesey Medical Scholarships (two).	£35 each.	1 year.	Subjects: ZOOLOGY, BOTANY, and CHEMISTRY.	These Scholarships are open to all students preparing for a Medical Course who shall not have attended Lectures or Laboratory Courses on Human Anatomy or Physiology, or a purely Medical or Surgical Course in the Owens College or any other Medical School in the United Kingdom. Candidates must not be more than 25 years of age on October 1st of the year of competition. Scholars must immediately on election enter for a full course of medical studies.
	Robert Platt Exhibitions (two).	£15 each.	—	—	First and second year students in Physiology.
	Sidney Renshaw Exhibition.	£15	....	—	Second year students in Physiology.
	Professor Tom Jones Exhibition in Anatomy.	£25.	—	—	First year students in Anatomy.

* Open to men candidates only.

† Open to women candidates only.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
OWENS COLLEGE, MANCHESTER—*continued.*	Turner Scholarship.	£20.	— —	Subjects: MEDICINE, PATHOLOGY (written and practical), OBSTETRICS, PRACTICAL SURGERY, OPHTHALMOLOGY, FORENSIC MEDICINE, and PUBLIC HEALTH.	Students who have completed a full course of medical study in the College are eligible only.
	John Henry Agnew Scholarship.	£30.	— —	The Scholarship is awarded on the results of an Examination, partly written and partly clinical, on DISEASES OF CHILDREN, MEDICAL AND SURGICAL.	Open for competition annually to all students in the Medical Department who have pursued a regular course of medical study in the College extending over a period of not less than 4 years or more than 6, and who have attended the course of lectures on Diseases of Children.
	Professor Tom Jones Memorial Surgical Scholarship.	£100.	1 year.	The scholar will be elected on the result of evidence submitted by him.	Candidates must have either graduated in the Victoria University or have obtained the Diploma of the Conjoint Colleges.
	Dumville Surgical Prize.	£15.	— —	Subjects: SYSTEMATIC, PRACTICAL, and OPERATIVE SURGERY, SURGICAL ANATOMY, and SURGICAL PATHOLOGY.	
BRISTOL ROYAL INFIRMARY AND BRISTOL GENERAL HOSPITAL.	University College Bristol Entrance Scholarship	£50.	— —	Competitive Examination in Subjects of GENERAL EDUCATION.	Open to Perpetual Students of Faculty of Medicine, University College, Bristol.
	Lady Haberfield Entrance Scholarship.	Interest of £1000.	— —	Ditto.	
	Tibbitts Surgical Prize.	£9 9s.	— —	Proficiency in PRACTICAL SURGERY.	
	Martyn Memorial Pathological Prizes.	Two annually, of £10 each.	— —	Competitive Examination in PATHOLOGY and MORBID ANATOMY.	
	A Gold and a Silver Medal.	— —	— —	Given by the Committees of the two Institutions to most distinguished Students of Fifth Year.	
Bristol Royal Infirmary ..	Suple Medical Prize.	Gold Medal value £5 5s. and £7 7s. in money.	— —	Competitive Examination in MEDICINE to Students of Fourth and Fifth Years.	Restricted to Perpetual Students who have done the necessary qualifying work at the Bristol Royal Infirmary.
	Suple Surgical Prize.	Gold Medal value £5 5s. and £7 7s. in money.	— —	Competitive Examination in SURGERY of Students of Third and Fourth Years.	
	Clark Prize.	£11 11s.	— —	Class Work of Third-year Students.	Restricted to Perpetual Students who have done the necessary qualifying work at the Bristol Royal Infirmary.
	Crosby Leonard Prize.	£7 7s.	— —	Examination in CLINICAL SURGERY.	
	Augustin Prichard Prize.	£7 7s.	— —	Examination in SURGICAL ANATOMY.	
Bristol General Hospital ...	Sanders Scholarship.	£22 10s.	— —	Competitive Examination in MEDICINE, SURGERY, and MIDWIFERY of Fourth-year Students.	Restricted to Perpetual Students who have done the necessary qualifying work at the Bristol General Hospital.
	Clarke Scholarship.	£15.	— —	Competitive Examination in SURGERY among Students of Fourth Year.	
	Marshall Prize.	£9.	— —	To the best Surgical Dresser of the year.	
LEEDS SCHOOL OF MEDICINE (YORKSHIRE COLLEGE).	Entrance Scholarship.	£67 4s.	— —	Competitive Examination among Medical Students who have passed Preliminary Scientific Examination at London or Victoria University.	Complete Course of Lectures and Practical Classes at Leeds School.
	Infirmary Scholarship.	£42.	— —	Competitive Examination in ARTS among Students who have passed one of the Preliminary Examinations.	Complete Course of Hospital Practice and Clinical Lectures at Leeds Infirmary.
	Hardwick Prize.	£10.	— —	Competitive Examination among Clinical Clerk Students of two years' standing in CLINICAL MEDICINE.	
	McGill Prize.	£10.	— —	Competitive Examination among advanced Surgical Students in CLINICAL SURGERY.	
	Thorp Prizes.	£10 and £5.	— —	Examinations in Forensic Medicine and Hygiene.	
	Thorp Prize Essay.	£15.	— —	Essay or research on some subject connected with FORENSIC MEDICINE, TOXICOLOGY, or PUBLIC HEALTH.	Every three years to former student of the Leeds School.
	Scattergood Prize.	— —	— —	Examination in MIDWIFERY.	

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
UNIVERSITY COLLEGE, LIVERPOOL.	Robert Gee Entrance Scholarships (four annually).	£25 each.	1 year.	Special College Scholarship Examination held in May.	First M.B. Course.

Annotations.

"Ne quid nimis."

THE ROYAL COMMISSION ON TUBERCULOSIS.

A ROYAL Commission has been appointed having for its purpose to determine with respect to tuberculosis these points: (1) whether the disease in animals and man is one and the same; (2) whether animals and man can be reciprocally infected with it; and (3) under what conditions, if at all, the transmission of the disease from animals to man takes place, and what are the circumstances favourable or unfavourable to such transmission. The following are the Commissioners:—Sir Michael Foster, M.P., K.C.B., F.R.S., M.D., Professor of Physiology in the University of Cambridge; Dr. German Sims Woodhead, F.R.S. Edin., Professor of Pathology in the University of Cambridge; Dr. Sidney Martin, F.R.S., Professor of Pathology at University College, London; Professor John McFadyean, Principal and Professor of Comparative Pathology and Bacteriology at the Royal Veterinary College; and Professor Rubert William Boyce, Professor of Pathology at University College, Liverpool. This is a very strong Commission; scientific and practical knowledge will be combined at its councils to a remarkable extent.

LOOKING BACK: CHESS PROBLEMS.

THE following excerpt is taken from THE LANCET of Sunday, Nov. 9th, 1823:—

"In a former number (THE LANCET, Oct. 19th, 1823) we gave some account of the origin of the game of chess. This is perhaps the only game to which the medical student may profitably devote any portion of his time and attention. It is liable to none of the objections which apply to games of chance; it holds out no encouragement to cupidity; and while it affords an agreeable relaxation from more serious pursuits it strengthens the intellectual faculties by the unremitting attention which it demands, and may even have some influence on our moral habits by the lessons of foresight, patience, and perseverance which it inculcates. To avoid errors on the one hand by foresight and circumspection, and to endeavour to retrieve such as are committed on the other by patient industry and perseverance—these are maxims applicable to all professions and situations in life and which, as the American philosopher Dr. Franklin has observed, are constantly illustrated on the chess-board. The study of chess has, we believe, been recommended to medical students by the distinguished professor[1] whose lectures stand at the head of this publication and who unites to his great professional and general knowledge a very considerable degree of excellence in that scientific game. The recommendation was founded, not only on the superiority of this amusement to all others in an intellectual point of view, but upon a more benevolent motive, for circumstances might possibly occur in which the surgeon's acquaintance with chess might relieve the mind as much as his professional skill could mitigate the bodily sufferings of his patient. Sanctioned by such an authority we have no hesitation in recommending the study of chess to such younger members of the profession as are unacquainted with its principles, and for those who have already made some proficiency in the game we shall in this and every succeeding number insert a few problems as an exercise of their skill and ingenuity. Many original positions will be given and others will be selected from sources not generally accessible. The solutions will be given at the end of each volume of THE LANCET, but it cannot be too strongly impressed upon the student in chess that the whole benefit to be derived from the study of problems must depend on his solving them *proprio marte* and resolutely forbearing to consult solutions."

Everybody will agree for the most part with our remarks upon the subject of chess made nearly eighty years ago. But nowadays probably no one would say that chess is "perhaps the only game to which the medical student may profitably devote any portion of his time and attention." At the present time most persons would say that outdoor games, cricket, lawn-tennis, football, hockey, or fives, are far preferable to any indoor game. But in the "twenties" football and cricket were in their infancy, if we may judge from the account of the latter game as given in "Pickwick, although the game was played and the Founder of this journal was in his student days an enthusiastic cricketer. Almost the only other recreations open to the medical student of 80 years ago were boxing and billiards. Chess, of course, even apart from its intellectual value, has its advantages. It requires no outlay of money and but two players, while between two fairly equal antagonists one game lasts a long time. Of sedentary games it is the best, for the possible combinations and complications are more numerous than occur in any card games, while there appears to be no incentive to stake money on the result. The excitement of the game is sufficient by itself.

THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope, received at the Colonial Office on August 28th, states that for the week ending August 24th the cases of bubonic plague in the Cape Peninsula numbered 2, both being in Europeans. At Port Elizabeth the cases were: Europeans, 1; coloured persons, 1; Chinamen, 2; natives, 4; total, 8. All other places reported no cases. The deaths from plague in the Cape Peninsula numbered 1, the patient being a Malay. At Port Elizabeth the deaths were as follows: Europeans, 1; coloured persons, 1; Chinamen, 1; natives, 2; total, 5. All other places reported no deaths. The area of infection remains unchanged and no cases of plgue have occurred among persons under naval or military control. As regards Mauritius a telegram from the Governor, received at the Colonial Office on August 30th, states that for the week ending August 29th there were 5 cases of plague with 2 deaths. As regards plague in Egypt, during the week ending August 25th 3 cases of plague and 2 deaths from the disease have been reported throughout Egypt. Of these 2 cases and 2 deaths occurred at Port Said among natives and 1 case occurred among Europeans at Alexandria. The last case of plague notified from Zagazig occurred on August 9th.

PETROLEUM LAMP ACCIDENTS.

WE notice in the annual report of the chief officer of the Public Control Department of the London County Council, which has been recently published, that the Council's inspectors have investigated during the past year, 1900-1901, the causes of 204 lamp accidents, 25 of which were fatal and involved the loss of 26 lives. The number of accidents is only one more than the number investigated in the year 1899-1900, but there have been three more lives lost. It is most interesting to point out that according to this return only 6 out of a total number of 25 fatal accidents occurred during the hot months of summer, one in June, two in July, and three in August, and if we remember rightly the hot weather last year did not really commence till after the middle of June, and then at times the temperature in the shade reached again and again, and even exceeded, as it has done this year, the flashing-point of the lamp-oil mostly sold. On the other hand, six cases occurred in the cold month of December, three in November, two in January, two in February, two in March, two in September, one in May, and one in October—a total of 19 fatal cases in the winter and autumn months. Lamps are, of course, used for a longer period in the winter months and the chances of accidents are increased, whatever they may be due to, but it is remarkable that in the hot summer months, when the temperature is frequently over 80° F. in the shade (well above the usual flashing-point of the oil), accidents are decidedly few when compared with the winter months.

---

[1] Sir Astley Cooper.

THE REFORM OF THE ROYAL ARMY MEDICAL CORPS.

As we write the report of the commission at present sitting on Mr. Brodrick's scheme for the reform of the Royal Army Medical Corps is on the eve of being made public; in fact, before we go to press, the scheme may be in the hands of our readers, for we understand that it only requires the Royal sign-manual to be promulgated. We have reason to believe that the terms offered to the Royal Army Medical Corps under this scheme will be found to be liberal and that the desires of the profession will be met by conferring advantages on those who display professional zeal and ability.

DR. ALFRED EDWARD AUST LAWRENCE, consulting physician accoucheur at the Bristol General Hospital and professor of midwifery and diseases of women in University College, Bristol, died suddenly last week while on a holiday with his family at Bishopsteignton, Devon.

SURGEON-GENERAL H. SKEY MUIR, Deputy Director-General of the Royal Army Medical Corps, has been offered extension of service to Dec. 31st next, instead of retiring by age on Oct. 4th. This officer is now on leave of absence until about Sept. 25th, and officers of the Royal Army Medical Corps writing more or less officially for information are requested to note this. Such correspondence should be directed to the Deputy Director-General if a reply is desired.

OPENING OF THE MEDICAL SCHOOLS:

WINTER SESSION 1901-1902.

LONDON.

St. Bartholomew's Hospital.—The session will begin on Tuesday, Oct. 1st. The old students' dinner will be held on the same evening in the great hall of the hospital at 6 30 for 7 o'clock, Mr. W. J. Walsham, F.R.C.S., in the chair.

Charing-cross Hospital. — The session will begin on Wednesday, Oct. 2nd, when Mr. J. W. Taylor, F.R.C.S., Professor of Gynæcology in the University of Birmingham, will deliver an introductory address at 4 P.M. The old students' dinner will be held at the Hôtel Cecil on Tuesday, Oct. 22nd.

St. George's Hospital.—The session will begin on Tuesday, Oct. 1st, with an introductory address at 4 P.M. by Dr. P. W. Latham. The annual dinner will be held on the same evening at the Hôtel Métropole at 6.30 for 7 o'clock, when the chair will be taken by Mr. Warrington Haward.

Guy's Hospital.—The session will begin on Tuesday, Oct. 1st, on the evening of which day a house dinner of the Students' Club will take place in the college dining hall. Application for tickets to the dinner should be made to Mr. A. W. Ormond, the secretary of the Students' Club, Guy's Hospital, S.E The first meeting of the Physical Society will be held in the new Physiological Theatre at 8 P.M. on Saturday, Oct. 5th. Sir Samuel Wilks, Bart., F.R.S., will preside, and a paper will be read by Mr. S. W. Mac Ilwaine on Disease and its Causation. After the meeting a conversazione will be held in the new laboratories and class-rooms. All past and present students are cordially invited to the meeting.

King's College Hospital.—The session will begin on Tuesday, Oct. 1st. The old student's dinner will be held in the evening at the Hôtel Cecil, when Mr. Paul Swain, F.R.C.S., will take the chair.

London Hospital.—The session will begin on Tuesday, Oct. 1st. The old students' dinner will be held in the college library, Dr. F. J. P. Daly in the chair.

St. Mary's Hospital.—The session will begin on Tuesday, Oct. 1st, with an introductory lecture by Dr. G. William Hill, aural surgeon. The annual dinner of past and present students will take place on Wednesday, Oct. 3rd, at the Whitehall Rooms, Hôtel Métropole, Colonel A. B. R. Myers in the chair.

Middlesex Hospital—The session will begin on Tuesday, Oct. 1st, when Mr. T. H. Kellock, M.A., M.D., F.R.C.S., will give an introductory address, after which the prizes gained during the previous year will be distributed, by Lord Howard de Walden. The annual dinner of past and present students will take place the same evening at 7 o'clock at the Trocadéro Restaurant, under the presidency of Mr. J. Bland-Sutton, F.R.C.S.

St. Thomas's Hospital.—The session will begin on Wednesday, Oct. 2nd, when the prizes will be distributed by Major-General Sir Ian Hamilton, K.C.B., in the Governors' Hall, at 3 P.M. During the afternoon the various departments of the hospital and school will be open for the inspection of visitors. The annual dinner, in which all former and present students are invited to join, will take place the same evening at the Whitehall Rooms, Hôtel Métropole, at 6.30 for 7 o'clock, Mr. H. H. Clutton in the chair.

University College Hospital.—The session will begin on Tuesday, Oct. 1st, when an introductory lecture will be given at 4 P.M. by Professor J. Risien Russell. The Past and Present Students' Dinner will take place at 6.30 the same evening at the Hôtel Cecil; Sir Richard Douglas Powell, Bart., will preside.

Westminster Hospital.—The session will begin on Tuesday, Oct. 1st. The annual dinner will take place on Oct. 4th, Mr. Charles Stonham, F.R.C.S., in the chair. The secretaries of the dinner are Mr. E. Canny Ryall, F.R.C.S., and Mr. W. Turner, F.R.C.S.

London (Royal Free Hospital) School of Medicine for Women.—The school will reopen on Tuesday, Oct. 1st, when the introductory address will be given by Dr. F. W. Andrewes at 4 P.M.

London School of Tropical Medicine.—The session will begin on Tuesday, Oct. 1st.

Pharmaceutical Society of Great Britain.—The inaugural address will be given on Oct. 1st at 3 P.M., by Professor Ramsay, F.R.S.

Dental Hospital of London.—The session will commence on Oct. 1st.

National Dental Hospital and College.—The session will commence on Tuesday, Oct. 1st.

PROVINCIAL.

University of Birmingham.—The session will begin on Tuesday, Oct. 1st.

University College, Bristol.—The session will begin on Tuesday, Oct. 1st.

University College, Cardiff.—The session will begin on Monday, Oct. 7th.

Yorkshire College, Leeds.—The session will begin on Tuesday, Oct. 1st. Sir William S. Church will deliver the introductory address on the following day.

University of Durham.—The session in the Medical Faculty will begin on Tuesday, Oct. 1st.

University College, Liverpool.—The session will begin on Tuesday, Oct. 1st. The opening address will be delivered and the prizes distributed on Saturday, Oct. 12th, by Professor Lodge of Birmingham.

Owens College, Manchester.—The session will begin on Tuesday, Oct. 1st.

University College, Sheffield.—The session will begin on Tuesday, Oct. 1st, when Sir Thomas Barlow, Bart., K.C.V.O., will deliver an introductory address.

SCOTLAND.

University of Aberdeen.—The session will commence on Tuesday, Oct. 15th.

University of St. Andrews (United Colleges of St. Andrews and University College, Dundee).—The session will open on Wednesday, Oct. 9th.

University of Edinburgh.—The session will begin on Tuesday, Oct. 15th.

University of Glasgow.—The session will open on Thursday, Oct. 17th.

Anderson's College, Glasgow.—The session will begin on Thursday, Oct. 17th.

St. Mungo's College, Glasgow.—The session will begin on Thursday, Oct. 17th.

Queen Margaret College, Glasgow.—The session will begin on Thursday, Oct. 17th.

IRELAND.

Queen's College, Belfast.—The session will begin on Tuesday, Oct. 15th.

Queen's College, Cork.—The session will begin on Thursday, Oct. 17th. The lectures will commence on Monday, Oct. 21st.

University of Dublin.—The session will begin on Thursday, Oct. 10th.

Royal College of Surgeons in Ireland.—The session will commence on Tuesday, Oct. 1st.

MEDICAL TEACHERS

Mr. R. O B Kerin, B.A., London, first in First Class Honours in Classics, assisted by a staff of B A. and B Sc. Honour Graduates, prepares candidates in class and by private tuition for Medical Prelimi [illegible] Inter Science, [illegible] d, Oxon, and [illegible] tories For last [illegible] Hospital Science [illegible] lane, W C. Mrs. Emil Behnke gives instruction in Voice Training and treats Stammering and other Defects of Speech at 18, Earl's-court-square, S W

Correspondence.

"Audi alteram partem"

"HARVEST BUGS."

To the Editors of The Lancet.

Sirs,—Is your correspondent Mr A Maude quite correct in all that he writes in The Lancet of August 24th with regard to harvest bugs? I am a layman and I do not claim to have made careful observations, nor can I distinguish between varieties of insects of the same objectionable propensities all of which I have been in the habit of anathematising under the same name. I am, however, a little surprised to learn that they inhabit "dry grassy places or chalky soil and near the sea," a sentence apparently intended to imply that they are found exclusively in such localities, or that, at all events, they are not to be expected elsewhere, and also that "they comparatively seldom attack men, as very moderately thick stockings and drawers prevent them from biting I admit that I was attacked by them recently near the sea (but not on a chalky soil or in a grassy country), while my host, who wore thick stockings, not only escaped but had informed me that they were unknown in his district. I met, however, a gentleman farmer near here yesterday, who was suffering severely from them and I expect to suffer myself more or less when partridge shooting begins I should have thought they were fairly universal, that stubbles were at least as productive of them as grass, while men were particularly liable to their attacks because they go more in long grass and into cornfields than do women I have never heard, by the way, whether agricultural labourers suffer from them or not Men do not as a rule wear thick stockings or drawers in August or early in September, but I have been bitten, or burrowed into, by them through fairly thick stockings when wearing knickerbockers and certainly through, or under, elastic stockings worn for varicose veins I notice that Mr Maude speaks of their attacking women round the ankles and waist. I have usually myself had them at the ankles or in places where my elastic stockings were tight, or (so I thought, at any rate) under the garters, and I always imagined that they found the skin warm, moist, and easy to work in at such points as these, but they can hardly be said to be particular They are also, I believe, to be found in hops and attack ladies and children, who gather them in the hedges, in the upper parts of their bodies With regard to prophylactic measures I have seen the free use of carbolic soap recommended in the *Field* and also sponging with Jeyes' fluid diluted with water I have tried the latter, and also sanitas, with some success, but they are rather highly-scented remedies for anyone who is going to mix with his fellow creatures It will be noted that the measures I have mentioned were advised in a sporting newspaper for the benefit of men, and I believe that one of them was the suggestion of a gentleman living in this county. With regard to the cure I venture to suggest that something oleaginous is fairly effective Most people use carbolised oil if they can get it, but I fancy that vaseline or any oil or ointment that will soak into the skin will serve

I am, Sirs, yours faithfully,

Midgham near Reading August 26th, 1901 E A Armstrong

Births, Marriages, and Deaths.

BIRTH

Gale —On August 31st, at Norton Woodseats, Sheffield, the wife of Arthur Knight Gale, L R C P Lond, M R C S, of a son

MARRIAGES

MARRIAGE OF COUSINS

To the Editors of The Lancet

Sirs —I have been consulted as to the advisability of marriage in the case of two young people who are first cousins Can any of your readers assist me in giving an opinion?—I am Sirs, yours faithfully,

Sept 2nd 1901 D F

⁂ When cousins are healthy and have no proclivity to hereditary disease they may safely marry, but the existence of a strongly-marked predisposition to tuberculous or other taint should prevent such marriages Marriage with cousins exaggerates the influence of heredity —Ed L

◆

Salvator —There is no objection to a medical man limiting his dispensary practice to a speciality if he has made a study of that particular branch of medicine Medical men resent, and with reason, one *of their number setting up among them as say, an ophthalmic* or an aural surgeon who has had no greater opportunity than any of them for acquiring particular knowledge in either direction On the other hand medical men are often glad to have someone resident among them in the district who is devoting his attention to certain special lines of knowledge and are glad to consult him in his special capacity

A M O H S —The practice is a very young one and in ordinary circumstances we should have thought that a year's purchase would have been the proper price but only someone who has had access to the books, as well as an opportunity of seeing the kind of work done, can give an opinion of practical value We recommend our correspondent to have the books audited If the report is favourable, as a good introduction is offered the bargain may be worth considering

Open Air —We regret to say that there are at present no sanatoria open for the reception of poor patients Some of the counties but as yet only a few, have begun to take action towards providing accommodation for the open air treatment of tuberculosis

Surgeon.—The practitioner mentioned had evidently attended the child previously to conjointly with or at a later date than our correspondent attended In any of these cases he would be legally justified in giving a death certificate

OUR CURRENT NUMBER

Being almost exclusively devoted to information especially interesting to Students we are necessarily compelled to defer the publication of communications on other important subjects.

We tender our best thanks to those gentlemen who have at considerable personal trouble kindly supplied us with the returns and prospectuses upon which the information given in this Students' Number of THE LANCET *relative to the various medical examining bodies, hospitals, and medical schools of the United Kingdom is based. We regret that in some cases, however, owing to proofs having been either not returned at all or too late, certain inaccuracies may be found.*

TO ADVERTISERS.

Owing to the pressure on our advertisement columns this week some announcements have unavoidably been held over.

Communications, Letters, &c., have been received from—

An original and novel feature of 'THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

A Poſt-Graduate Lecture

ON

CHRONIC INVALIDISM IN WOMEN, ITS CAUSES AND CURE.

Delivered at the Medical Graduates' College and Polyclinic

BY W. S. PLAYFAIR, M.D., LL.D., F.R.C.P.,
EMERITUS PROFESSOR OF OBSTETRIC MEDICINE AT KING'S COLLEGE AND CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL.

GENTLEMEN,—The subject I have chosen on which to address you this afternoon may possibly strike you as too common-place for discussion before a post-graduate audience. There is no elaborate pathology connected with it. I shall not have to demonstrate to you any of the mysteries of modern bacteriology. I shall only have to discuss with you very common-place states of ill-health, their causes, and their treatment. But if the importance of morbid conditions is to be estimated not only by their structural alterations but also by their frequency in every-day practice and by the amount of suffering which they cause to the patients and to the other members of her family, then I think the topic of this lecture will be admitted to be of no slight importance from a practical point of view, and to be well worthy of the study of the practitioner. If you will carry your minds back to your acquaintances there is probably no one of you who will not recollect among the families you know some where there is an example of the type I am alluding to—some bed-ridden or sofa-ridden lady who is perpetually being "doctored," who is going from one health resort to another, who is swallowing bucketfuls of drugs, who is dragged about in bath-chairs, who is a centre of attraction to sympathising friends, earnest curates, Christian scientists, *et id genus omne*, who steadily make her worse, until her sick-chamber becomes a morbid centre the evil influence of which dominates all who come in contact with her, and makes too often a home which ought to be bright and cheerful a misery to all connected with it.

In studying this subject we are at first struck with the fact that the disease or group of morbid symptoms we are discussing has not until comparatively lately held a recognised place in our text-books or catalogues of diseases. It is common enough in all conscience, but its symptoms are so various, and often so indefinite, that they do not readily lend themselves to classification and description. There are no characteristic signs such as we have in definite structural diseases, as in pneumonia, apoplexy, peritonitis, and the like, by which it can be certainly diagnosed. The symptoms being altogether functional this can hardly be expected, since functions of all sorts and kinds, of all parts of the body, are concerned, and wide clinical experience is required to recognise and understand them properly. Even a name has been wanting until of late. Obviously, illnesses so common have not passed altogether unrecognised. Under the divisions, "Nervousness," "Hysteria," and "Hypochondria," Whytt published a remarkable essay in the middle of last century which clearly foreshadowed a knowledge far in advance of his time, and I am not sure that any better or more accurate classification of common types of the disease has even yet been given. Then "spinal irritation" was used as a descriptive term, and it was not a bad one, although I well remember when I was a student hearing it denounced as a thing that did not exist and the very mention of which we should be careful to avoid. Under the names of "nevroisme," "nevropathie," and "nervous exhaustion" the same form of disease was described, [illegible] that the term "neuras[illegible] the proper designation, [illegible] by all recent writers. I confess that I have never much liked it, but that is perhaps because I have unconsciously shared the prejudice that existed in the minds of many men against a term which it must be admitted was often enough associated with some forms of practice perilously near what we call "quackery," and yet, after all, it is a name which pretty accurately describes what is the real essence of the diseases and no one has suggested a better, so *faute de mieux* we must use it.

One reason why this type of disease has not been hitherto properly recognised and dealt with in our systematic treatises on medicine is that it is essentially a disease of the cultured and educated classes. It occurs in those whose nervous systems are of the mobile and emotional kind, the result of either heredity, defective education, training, or the like. It is rarely, if ever, met with in hard-working women of the so-called lower class who have to work for their living and for their families by the sweat of their brows and who have no time to give way to "nerves." Therefore, it is rarely met with in hospital wards or out-patient rooms where the authors of our text-books have gained their clinical experience. It is satisfactory, however, to know that of late years it is not only recognised as a distinct and most important type of disease, and described by Dr Weir Mitchell, Dr. T. Clifford Allbutt, Mr. Victor Horsley, and others, but that the principles which should guide us in its management have been fully recognised, and that types of illness formerly considered quite hopeless are now, in the majority of cases, amenable to treatment and very generally restored to health. When you reflect that until quite recently these cases were left rigidly alone as being the despair of the physician, that, as a matter of fact, from their very nature ordinary "doctoring" only added fuel to the flame and made them distinctly worse, then it must be admitted that to have thoroughly mastered their nature and to have devised a systematic method of treatment which recognises the essential nature of the disease, and in nine cases out of 10 enables us to restore the patient to perfect health, must be admitted to be a great clinical discovery—I do not think I am exaggerating in calling it one of the greatest clinical discoveries of the past century.

The subject is so large and may be considered from so many points of view that I do not propose to discuss at length the symptoms and general characteristics of neurasthenia. It would be impossible to compress into the limits of a single lecture what should be said on this topic. I shall therefore consider some aspects of it only—chiefly how best such nervous states are to be prevented, since it is a truism that that is even better than curing them; and next how they are best dealt with, since many absolutely curable cases are spoilt by imperfect and badly carried out methods of treatment, owing to lack of experience on the part of the medical men who undertake their management. In the latter topic I shall have to deal with the so-called "rest cure" or the "Weir-Mitchell treatment" which has of late years attracted a good deal of attention, and in the carrying out of which little practical experience can be gained by the practitioner in the course of his studies, since the form of illness to which it is appropriately applied is not met with in our hospital clinics. As I have paid a good deal of attention to this matter I hope it may not be altogether without profit to you if I detail to you some of the lessons which my work in this direction has taught me.

How I came to work at this subject is sufficiently curious. I daresay you know that gynæcologists have had in their day to submit to a good deal of criticism from their medical brethren. I daresay it was all very well meant and I am sure that it was useful. We were told that gynæcological treatment very often did a great deal more harm than good, that it concentrated the attention of patients on their own ailments, and that it very frequently led to a state of chronic illness of the most aggravated type. My good friend Dr. Clifford Allbutt told us in his excellent lectures at the Royal College of Physicians of London that when a woman fell "into the net of the gynæcologist" she was a lost woman indeed, and that her only hope of salvation was that the gynæcologist should take a holiday in the Upper Engadine or go salmon-fishing in Scotland. Now, I am not disposed to deny that there was some measure of truth in this. Gynæcologists are no more free from error than the rest of their medical brethren, and the tinkering style of gynæcology that some 20 years ago led to a very exaggerated belief in the importance of certain local conditions, now much more judiciously dealt with, such as cervical erosions and uterine malpositions, often led to much too frequent and injudicious local treatment that frequently had a disastrous effect on the patient. "For God's sake tell me, am I displaced?" was the despairing cry once made to me by a lady who had suffered many things from many pessaries and it indicated a frame of mind far from uncommon then and which led to much evil. At any rate, I took to heart

No. 4073.

the criticisms of our kind friends, and so it came to pass that I paid more and more attention to the chronic state of general ill-health so often associated with uterine disease and have had the opportunity of seeing many interesting examples of the effect of morbid nervous conditions in producing the illnesses described as "neurasthenic," or "chronic invalidism," on which I am now addressing you.

And first as to prevention. How are we to educate and bring up our young women of the middle and upper classes so as to minimise as far as possible the chance of neurotic break-down in after life? The true secret of this I believe to be found in the old adage, "*Mens sana in corpore sano.*" My belief is that the thoroughly strong-bodied, healthy girl very rarely lapses into the invalid woman, or perhaps it would be more accurate to say that a thoroughly healthy body is the best safeguard against her doing so. Unfortunately, the higher class of mental training now so prevalent amongst girls, against which I have nothing to say, often leads to conditions very much opposed to physical health. A great many of the mistresses of high-class schools start with the absolutely erroneous theory that there is practically no distinction between the sexes at and about the period of puberty, and little or no attention is ever paid to the all-important function of menstruation. The feeling of most school-mistresses seems to be antagonistic to admitting that any inquiries should be made on such an important subject. I have seen dozens of girls whose health has broken down at school, and in no single instance that I can recall was the mistress aware that long before symptoms of breakdown became prominent nature had thrown out danger-signals, such as amenorrhœa, menorrhagia, headaches, emaciation, and the like, which, if they had been attended to, would certainly have prevented much future evil. So long as school-mistresses go on the theory that men and women are alike and should be treated as being alike, and that the differences between them will disappear when women are not prevented by evil traditions from sharing with perfect equality the ambitions and occupations of the other sex, so long will evil certainly arise. Work, and hard work, need do no mischief *per se* if properly safeguarded. The successes of women in the higher examinations, the universities, the medical schools, and so on, are more than sufficient proof of this. But while the boy's health at school is safeguarded by outdoor exercise, cricket, football, and the like, which are not optional but compulsory, the schoolgirl's outdoor exercise is too often limited to a walk or possibly to a visit to the gymnasium, with a time-table of from seven to eight hours' hard indoor work. If the girl is languid and ailing even this is not insisted on, and she may spend her leisure time indoors in a hot and ill-ventilated room. Of course, the evils of the old type of girls' school have been pointed out, and I am happy to say that in many of the girls' high schools of to-day games thoroughly well suited to girls are actively encouraged and even insisted on, such as golf, hockey, and tennis, rowing where it is possible, and bicycling, which are better for the adolescent girl than the more violent type of games, such as cricket and football. The results, when such safeguards to education are systematically carried out, will be the production of a thoroughly representative type of the healthy-minded and healthy-bodied English girl, little prone to give way to morbid emotions, and thus fitted to bear the strain to which so many of them will certainly be subjected in after life by the trials of life and the worries of existence which cannot be avoided, which are the constant causes and precursors of the types of illness we are discussing.

The causes of developed neurasthenia are very multifarious, but my experience has taught me that two elements are rarely if ever absent, defective nutrition and some form of mental or emotional disturbance, which may perhaps be best described by the good old English word "worry." The one we might describe as the predisposing and the other as the exciting cause. Without the former the latter would probably have little effect. I have rarely, however, met with a pronounced case of neurasthenia in which some mental or emotional cause could not be traced. Amongst the most common I would mention grief of some kind or another, such as the death of a near relative, often ending in a prolonged strain affecting the body, with its sleepless nights and constant anxieties, or a disappointment in love, a cause of breakdown I have traced in very many cases of nervous illness; or, again, another cause, by no means infrequent, is monetary anxieties following sudden reverses in fortune. Here the nerve strain is often very great, for the patient may have had to take on herself responsibilities to which she had been totally unaccustomed in the endeavour to work for a living, the effort ending in complete collaps Excessive work, which is very generally considered a ferti cause of neurasthenia, is not, in my experience, by a means so important a factor as is generally believed, unle it is unwisely insisted on when the general health is defe tive. A healthy man or woman is capable of almost a amount of work—I should be inclined to say the more t better, provided the physical machinery of the body sound—but if the general health is bad, the appetite d fective, the nutrition below par, and the patient insists prolonged mental strain, anxiety in competitive examin tions, and the like, then of course the nerve irritation w tell and collapse ensue. The influence of heredity in pr disposing to neurasthenic conditions is certainly of gre importance. You will very often find in investigating t family history of a marked case of neurasthenia that the are cases of some other type of nervous disease amo relatives. I have frequently come across cases in which brother or sister, uncle or aunt, were insane. It might put into other words by saying that there is very general *a family tendency to mobile and emotional nervous system* The phlegmatic unemotional man or woman rarely becom neurasthenic.

It is not my intention to-day to direct your attention the symptoms of pronounced neurasthenia. Time wou entirely fail me, and I am rather desirous of giving you son practical hints as to treatment, especially as to the carryi out of the rest cure or systematic method of dealing wi properly selected cases, which we owe mainly to Dr. We Mitchell of Philadelphia, and which is very generally know by his name. Parts of this treatment were practised fro time to time, but a regular systematised method of deali with these difficult cases, based on an accurate conception their essential nature, was certainly never suggested anyone else. The results have been, in well-selected case often so miraculous that it is not astonishing that th should have attracted a good deal of attention and that th method of treatment should have been extensively tri Unfortunately, the proper carrying-out of the rest cu requires several conditions which are often wanting. O is a special aptitude and experience on the part of t medical man who conducts it; it is a little like playing t fiddle—unless the musician has some experience and practi in his instrument he will certainly fail to produce go music. So with this. Many men seem to think that th can play this instrument without any trouble. They fail realise that an emotional nervous woman is a very diffic subject to deal with. Either they adopt the totally erroneo method of bullying and scolding her as if she were a naugh child or they let her dominate and have her own way everything—an error quite as fatal. How either fault is be avoided it is not easy to tell. Some men carry out th treatment very easily and successfully. They are the me whose will and personality are strong, but in whom the ste gauntlet is very thickly coated with velvet, so that th patient fails to see that the steel is there. Certainly if th medical man is unable to gain the respect as well as th affection of his patient he is not likely to be very successfu

The selection of a proper nurse is almost as important a that of the medical man. It is my experience that thre nurses out of four, however experienced they may be in othe branches of their work, are absolutely useless in cases of th kind. There is an indefinable quality of tact which essential and which is very frequently wanting. Time aft time I have seen cases doing badly which have instantl begun to improve and have progressed steadily when th nurse has been changed. What is required are kindnes sympathy, intelligence, and firmness, and the possessor such a combination is a *rara avis* indeed. There a cases so simple to deal with that any nurse can manag them and others so difficult that only the most experience can properly deal with them.

The other error from which failure often arises is that th practitioner attempts to get over the real difficulties of th treatment by carrying it out in what he is pleased to call " modified way"—the modifications generally being such a necessarily preclude success. For example, one *sine qu non is complete removal of the patient from her hom* surroundings. This is necessarily costly and is certainl unpleasant. Strong pressure is invariably brought bear on the medical man to induce him to forego this to which the weak kneed man too often yields and attempts to treat the patient in her own house or admits the occasional visits of relatives and friends The result is almost invariably a disastrous failure, as the *attempt to play Hamlet with the part of* Hamlet left out is bound to be and so a really valuable treatment is discredited and a case which, properly treated, would certainly have been restored to health is little benefited

The rest cure may be described as based on two principles, one physical and the other psychological The former attempts the restoration to health of the body, the latter of the mental or nervous system, both of which are materially disordered. Here we have concisely the definition I have already given of a *mens sana in corpore sano* Let us now consider what we have to do in these directions, and first as to the physical parts of the treatment which aims at the restoration of the general health which is almost invariably at a very low ebb Probably for years the patient has been taking next to no food, often she is emaciated to an extraordinary degree Sometimes, especially in the case of hysterical women suffering from what has been called "apepsia nervosa," the extent to which this starvation is carried is quite astonishing Either from pure hysteria or as a consequence of dyspeptic symptoms one article of food after another has been dropped, until the patient has come to subsist on an almost starvation diet, barely enough to keep body and soul together All the body fat is absorbed, the muscles waste, and the patient often has the appearance of a living skeleton. These very emaciated cases are the exception They most frequently occur in hysterical girls, and, curiously enough, they are the easiest to treat and give the best results, and I have long come to the conclusion that the

his respect the better it is for treatment,
affords, as it were, a better leverage
say that I have never had to deal with
this type which I have failed to cure

Short of such cases, in the vast majority of neurasthenic and chronic invalids the general condition of the body is in a wretched state To get the body into good health we have to adopt some method which will effect this without calling on the will of the patient To tell such a wretched starved creature to eat rump steak or mutton chops would be as wise as to tell the tide to cease flowing, as Canute did. Doubtless she has been told to eat hundreds of times already, she can no more do it voluntarily than she can fly, nor can she do it by persuasion, bullying, or cajoling But, as you all know, when a man's or a woman's muscles are wasted by strong muscular exercises the muscle waste must be supplied by food, and even a healthy appetite becomes greatly stimulated when its owner is deer stalking cycling, or the like, and so "hungry as a hunter' exactly describes what takes place under such conditions. Now, in the "rest cure" this muscular waste is brought about vicariously and without any effort on the part of the patient by massage, shampooing, or whatever you choose to call it of her muscles by a skilled operator The patient is put to bed and is absolutely passive and inert, and by degrees her muscles are exerted for her by a competent masseuse for at least two hours twice daily Now on this therapeutic agent of massage—for it is simply a mechanical remedy, just as cod liver oil is a fluid one—I desire to say a word or two It is now nearly 25 years *since* I brought this method of dealing with a very important and

h case before the profession in this
e there was, so far as I knew, no such
be found I had to teach one or two
my own purposes from the few and
I could lay my hands on and I have
e else, although masseuses now exist
he thing has been the subject of quackery in
the very name of "massage" has become
Men have used quackery in its practice,

es have been written about it so as to turn a perfectly simple mechanical process into a mystery, and women have been humbugged into wasting their substance by paying large fees for learning it Worse still, it has been turned into a cloak for hideous pandering to vice, so that it has come to this, that so many abuses have grown up about it that it requires some moral courage to prescribe it at all. Many men have not that moral courage They talk of it as a thing no respectable practitioner would have anything to do with, and, since cases of the kind we are dealing with cannot possibly be cured without it, they leave them uncured Now this is a thing I cannot understand I loathe the abuses of massage as much as any man can the more so as I feel the responsibility of having *brought its use before the profession in this country* But my hands are perfectly clean and my conscience does not prick me I know that not to use it would be to deprive myself of a therapeutic agent which has been of infinite value to me, and I see no more reason why the quack should have the best remedies than Wesley saw why the devil should have all the best tunes The test of massage being well and effectively done is not the employment of useless and misleading names, such as "effleurage,' "pétrissage," and the like, about which I know nothing, which only serve to obscure a perfectly simple thing, but its effects in enabling the patient to consume and assimilate the enormous quantities of food required to build up the wasted tissues and to restore the bodily strength What it can do in this way is really astounding The patient being in bed and absolutely at rest she is given by the nurse first about five ounces of milk every third hour, which in a couple of days or so is increased to 10 ounces, so that she is soon taking about four pints in the course of 24 hours Then about the third day she has a breakfast consisting of a cup of cocoa, fish egg and bacon, or the like, and bread and butter, with which, like the milk, she should be fed by her nurse If the massage is being properly done by this time there is scarcely, if ever, any difficulty about this Then by degrees a light dinner is added, then a substantial meal in the middle of the day In 10 days at the most, in a case that is doing well, the patient is consuming an amount of food daily, and digesting it without difficulty, that no strong healthy man in good health could possibly take If you take, for example, this dietary that I extract at haphazard from the books I keep of the food taken by each patient you will see that this statement is not exaggerated —March 6th 8 A M, porridge and one gill of cream, 9 A M, breakfast, consisting of fish, boiled egg bread and butter, and cocoa, 10 A M, 14 ounces of milk 11 A M, raw meat soup and peptonoids, 12 noon, 2.30 P M, and 4 P M, 14 ounces of milk, 1.30 P M, lunch consisting of roast beef two vegetables bread, milk pudding and stewed fruit, 5 P M, raw meat soup and peptonoids, 7 30 P M, dinner, consisting of fish fowl two vegetables bread and sweets, 8 P M and 9 30 P M, 12 ounces of milk The milk, you will see totals up to 80 ounces or four pints I would defy any gentleman present to get through this if he tried It is really most interesting to watch a starved emaciated creature who possibly for years has been unable to take and digest anything beyond slops and beef tea, consume this enormous dietary with perfect ease and without repugnance, and to see how day by day she puts on weight gains colour, and gets the long lost appearance of good health I am accustomed to consider a gain in weight of eight pounds in the first fortnight after treatment has been commenced a fair average and subsequently a gain of two pounds a week. This I consider to be the best test of a case doing well and if in 10 days or a fortnight the patient is unable to consume all this food and is not putting on flesh at something like the rate I

thing wrong, either in the
be advisable to change the

whenever I have a case that is not doing well, and often *such a step is followed by the happiest results* Of course every now and again there is trouble with this exaggerated diet. Not infrequently there is an attack of bilious vomiting or diarrhoea but 24 hours' holiday from food, during which the patient takes milk only, almost invariably removes it and enables us to resume the former scale of feeding Others, on which I have no time to dwell, can only be dealt with by experience It is curious to see how with improved general health functions that have long been most imperfectly carried on become healthy For example, obstinate constipation which is exceedingly common disappears and without any special treatment the bowels act healthily and regularly So again with menstruation. Time after time I have seen this function which has been absolutely in abeyance for many years recur spontaneously within the six weeks or two months during which the patient is under treatment in a home or if not then at least within a few weeks later There are many other points in connexion with the physical aspect of the 'rest cure' on which I should like to speak to you but time makes it impossible You will observe that I have said nothing as to drugs. They are, indeed, of little consequence and the patient has doubtless already swallowed them in bulk. The only ones I ever give are some iron and arsenic, some aperient if required at first, and a tablespoonful of maltine two or three times daily.

The psychological aspect of the "rest cure" is as important as the physical and the one is necessarily interdependent on the other. You must bear in mind how all these chronic invalids have fallen into morbid grooves in the conduct of their lives. Almost always there is some injudicious relative and friend who, is, as it were, the slave of the patient, and who, generally from the highest motives of love and sympathy, unconsciously fosters all her evil habits. These motives, however, although right, are generally injudicious. To attempt to carry on the case under conditions in which the friends are in constant communication with the patient is to court failure. I am not prepared to say that a case can never be cured at home, but it is so seldom that the exception only proves the rule, and no wise man will run the risk. I have already hinted at some of the personal qualities which the medical man ought to possess if he is to conduct these cases successfully. Every case should be the subject of a careful psychological study. No two cases are the same, no two can be managed in the same way. Beyond any doubt I think there is a good deal of suggestion in this business. If the patient comes with the profound conviction that she is to be cured, whether she likes it or not, then the battle is half gained, but how that confidence and conviction are to be given to the patient it is not in my power to tell you. All I can say on this is that in nine cases out of 10 it can be done. But if you think that you can pull one way while you leave relatives, friends, and visitors to pull the other at their own sweet will by a word, a hint, or a look, then you will soon find out your mistake. Therefore I would insist most strongly that complete separation from ordinary surroundings, as in a suitable home or lodgings, should always be made an absolute *sine quâ non*. Even letters should be prohibited, at least at first. If after a week you find your patient doing well, then this rule may be safely relaxed. I generally keep my cases rigidly confined to bed for about six weeks; then I get them up for some hours and I set them to work with the nurse to go out daily, to walk an increasing amount, to go to theatres, churches, and concerts—in fact, to do whatever was impossible before and what is incompatible with the life of an invalid. Then, if the patient's means admit of it, I send her away with the nurse to travel abroad, to go on a sea voyage, or to the seaside, or to do whatever is most likely to suit the particular case, and when the patient has been got to walk five or six miles daily, to ride on horseback, to go out bicycling, and so on, then no one can say that she is an invalid; but I would not advise the patient in any bad case to go home to her former surroundings unless she has passed through some such tests as I have indicated. And when once she has done so the cure may be considered to be established. I have often heard objectors say that it is no use curing the patients in cases of this type—that the improvement will be only transient and that very soon they will be as bad as ever. Now, that is certainly not the case. Of course, it would be absurd and irrational to expect that no case ever relapses, but all I need say on this point is that my experience, which I can now claim to be very large, has convinced me that any real and permanent relapse is quite an exception and may be considered as a negligible quantity. Of course, every now and again it must happen, but its possibility should never be a ground for not trying to get the patient out of the slough in which she is lying Should a patient show any symptom of recurrence then the proper thing to do is to try to get her away from home for a week or two so as to nip the threatened danger in the bud. The one great objection that can be raised against this system of treatment is the very considerable expense that is necessarily associated with it and which I have never seen my way to get over. I once tried to treat cases in a private room at King's College Hospital, but they were found to be so costly to the institution, as well as troublesome, that the hospital authorities would not allow me to take in any more. I am afraid that any attempt to treat them cheaply will end in failure. All I can say on this is that there is nothing so expensive to a family as constant ill-health and that, therefore, the expenditure will generally be found to be a real economy in the long run.

THE OCCURRENCE OF GREEN OR BLUE URINE AND ITS MOST FREQUENT CAUSE

BY F. PARKES WEBER, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE GERMAN HOSPITAL, DALSTON.

So much has been written, especially in France, on the effects of the ingestion of methylene blue on the urine, that one would think that there was little more to be said on the subject. It happens occasionally, however, that apparently healthy subjects, mostly children, pass green or blue urine, though they are unaware of having swallowed methylene blue or any other similar anilin dye in any form. Medical men not familiar with the characteristic properties of methylene blue and the reactions of urine coloured with methylene blue are therefore very apt to seek some other explanation—for instance, such an unusual one as that indigo blue, derived by fermentation from indican, is present in the urine before it leaves the body. As a matter of fact, apart from the greenish urine resulting from the presence of biliverdin and apart from the somewhat greenish urine of carboluria, practically all cases in which green or blue urine is voided are due to the ingestion of methylene blue or a similar anilin dye, though some poisonous plants may make the urine green and Zülzer[1] recorded the case of a boy who became severely ill after eating the leaves of *Cytisus alpinus* and passed a large quantity of urine having a grass-green colour. I am even sceptical of the power of indigo, given medicinally or otherwise, to colour the urine green. At all events, whereas a capsule containing one decigramme of methylene blue will make the urine green or blue during the next three or four days, several doses of the same amount of indigo have no effect of this kind, the colour of the urine remaining unaltered or simply becoming yellower or more decidedly orange. I think that when apparently healthy persons in England pass green or blue urine without obvious cause the real explanation is *generally* that they have indulged in sweets coloured with methylene blue, particularly certain purple sweets. These latter contain a mixture of dyes and the urine passed after eating them is greenish. Thus, the supposed "unaccountable" secretion of green urine generally occurs in children and young women who like sweets. As a considerable quantity of sugar has to be swallowed for the urine to become deeply coloured (other kinds of sweets are likely to be eaten at the same time as those containing methylene blue) it is not surprising that some of those who secrete green urine should suffer from digestive troubles and a general metabolic disturbance, the latter showing itself by a sediment of uric acid or calcium oxalate[2] crystals in the urine. These disagreeable effects are certainly not so readily produced by swallowing pure methylene blue (medicinally) in considerably greater amount than that contained in the sweets.

Last April a practitioner gave me a specimen of green urine from a woman, aged 28 years, who had been passing similar urine for four days. The ordinary tests for methylene blue gave positive results, and though the patient was not aware of having taken methylene blue in any form she had, as she acknowledged, been eating sweets. The urine was of specific gravity 1023, acid, free from sugar and albumin, but loaded with small uric acid crystals. Perhaps some hepatic disturbance due to indulgence in sweets accounted for the uric acid sediment. Later, in June, through the kindness of Dr. A. E. Garrod, I obtained a specimen of bluish-green urine from a girl, aged nine years, together with a sample of sweets similar to those which she had been eating. The urine was of specific gravity 1022, acid, and free from albumin and sugar, but after standing it deposited a sediment of oxalate of calcium crystals. The ordinary tests showed that the colour was due to methylene blue. The sweets in question were violet or purple coloured, becoming opaque and more reddish on keeping. Three or four pieces swallowed experimentally sufficed to impart a green colour to the urine passed two or three hours afterwards, this green colour was shown by the ordinary tests to be due to methylene blue. In July a woman who attended as an out-patient at the North London Hospital for Consumption told me that her daughter, six years old, had recently had a peculiar affection. During about eight weeks the child from time to time passed greenish urine. The green colour used to be observed for two or three days consecutively every week, and only in the urine passed in the morning. I ascertained that the child had been occasionally eating purple coloured sweets though she preferred others when she had the choice. In this case I succeeded in getting some of the purple sweets from the maker. They were similar to those mentioned in the previous case, and after experimentally eating some of them greenish acid urine was excreted, giving the ordinary proofs of the presence of methylene blue.

---

[1] Harn-Analyse, p. 54, quoted by Dr. H. Morley Fletcher, Transactions of the Clinical Society of London, 1899, vol. xxxii., p. 49.

[2] There is no doubt that oxaluria may sometimes be regarded as a forerunner of alimentary glycosuria—that is, as being due to the same kind of metabolic disturbance which when more pronounced reveals itself by the presence of sugar in the urine. See Dr. Paul Mayer's excellent paper, "Ueber unvollkommene Zuckeroxydation im Organismus," *Deutsche Medicinische Wochenschrift*, 1901, Nos. 16 and 17. It is possible, however, that a dose of pure methylene blue without sugar may in some individuals produce or increase oxaluria.

I have taken considerable trouble to test the accuracy of various accounts of the characters by which a green or blue colouration of the urine may be recognised as due to methylene blue. Some mistakes in this connexion have been published, but I believe the following summary to be correct.

1. When a capsule containing one decigramme of methylene blue has been swallowed by a fairly healthy adult the urine passed an hour or so afterwards is already found to have a greenish tint. The urine voided later is deeper green, and still later it is blue. The colour is observed in the urine of the next three or four days, but becomes less intense and finally intermittent, the earliest morning urine being the best coloured. In some individuals a green tint may even be observed in the morning urine after five days, though the midday urine of the two preceding days has only the ordinary yellow appearance. This accounts for the history sometimes given that the green colour has been observed chiefly, or exclusively, in the morning urine—that is, in the urine secreted during the night's sleep. Thus when relatively small doses of methylene blue in the form of sweets are taken at intervals during several weeks, as in the third case which I have alluded to, it is not surprising to hear that during eight weeks the green was noticed only in the morning urine.

2. The colour of the urine varies from faint greenish-yellow to deep blue and depends, of course, on the amount of methylene blue and of the ordinary yellowish pigment present in the specimen. The urine quickly stains ordinary white writing- or blotting-paper blue.

3. The colour of the urine may sometimes be increased by boiling. This is because some of the methylene blue is excreted as a colourless "chromogen." The colour is brought back by heating the urine with acetic acid, as Achard and Castaigne[3] say, or, in acid urine at all events, as I have noted, merely by boiling it. The amount of methylene blue secreted as a colourless chromogen is very much greater in some animals (the dog, the rabbit, and the guinea-pig) than in man, and is increased by the presence of certain pathological conditions in man.

4. The colour of the urine is slightly lessened by filtering it. This is because part of the methylene blue is absorbed in staining the filter paper, and sometimes also because the urine contains suspended uric acid crystals stained with the blue which cannot pass through the filter paper.

5. The urine is decolourised by adding a solution of caustic potash without heating. A few drops of nitric acid will not effect this, but decolourisation can generally be effected by boiling with strong nitric or hydrochloric acid. The green or blue can be brought back by neutralisation.

6. Ether, when shaken up with the urine, does not become coloured, but chloroform takes up much of the dye and rapidly becomes blue. This it will *not* do with an ordinary aqueous solution of methylene blue. Generally, when shaken up with the latter, chloroform gradually becomes mauve, and afterwards purple or red, causing some diffuse absorption in the green of the spectrum.[4] It is probable, however, that the anilin dyes which after passing through the body appear in the urine as methylene blue are not all quite identical with each other—in other words, that there are different varieties of anilin dyes[5] resembling methylene blue which when absorbed from the alimentary canal are excreted in the urine as methylene blue. The blue colouration of chloroform by the methylene blue in the urine does not absolutely prove that the anilin dye has passed through the body, for outside the body ordinary methylene blue if dissolved in any urine, whether freshly passed or otherwise, becomes rapidly capable of giving the characteristic blue colour to chloroform.

7. On examining the green or blue urine with a good pocket spectroscope an absorption band can sometimes, but not always, be made out identical with that yielded by an aqueous solution of methylene blue. The absorption band can, however, be best examined in a pale blue chloroform solution derived from the urine. It is a clearly defined band in the red of the spectrum separated by a considerable space from the sodium band (Fraunhofer D), whereas the characteristic band from a chloroform solution of indigo (and of artificial indigo) is further from the red end of the spectrum and quite close to the sodium band. In more deeply coloured solutions of methylene blue there is a second band in about the position of the indigo band, and in still stronger solutions the two bands united spread out from the red into the yellow and green of the spectrum. If a greenish colour in urine is due to indigo blue the chloroform should take on a bluish tint somewhat different from that due to the presence of methylene blue and if the chloroform becomes sufficiently coloured the characteristic absorption band of indigo should be detected whilst that of methylene blue should be absent; moreover, when indigo is present the urine is likely to be decomposing and alkaline and by microscopical examination of the sediment the blue granules of the pigment will probably be seen.[6]

8. Methylene blue is reduced and decolourised by the vital action of living organisms. Consequently when urine containing methylene blue begins to ferment the lower portion of the liquid, owing to the action of the reducing microbes, loses its colour and only the upper surface retains it. There the anilin dye forms a thin blue or green film which cannot be decolourised because it is directly exposed to the oxygen of the air. On gently shaking up the liquid and thus mixing it with oxygen the colour may be seen rapidly spreading downwards from the surface until the original appearance of the whole is regained. If the decomposing urine is in a tightly corked bottle, but does not quite fill it, this beautiful experiment may be repeated several times, but at last all the oxygen in the bottle is used up by the reducing microbes and the urine by reduction entirely *loses its colour. Then* no amount of shaking will bring back the colour until the cork be withdrawn so as to let out the carbonic acid and admit oxygen. On taking such a bottle of decolourised fermenting urine out of a cupboard and withdrawing the cork and pouring out the liquid into a glass the colour rapidly returns and the erroneous conclusion may be arrived at that it is exposure to light instead of oxygenation which causes the colour to return. Such a mistake has been made, but Achard and Castaigne[7] drew attention to this decolourising effect of living organisms on methylene blue as far back as in 1897. The same action of living tissues explains why the ingestion of a considerable dose of methylene blue scarcely alters the colour of the living human blood and tissues. The methylene blue until it is excreted by the kidneys is present in the body as a

---

[3] Sur la Décoloration du Bleu de Methylène par les Éléments Vivants. Comptes rendus de la Société de Biologie, Paris, 1897, p. 1091.

[4] By spectroscopic examination of the reddish chloroform a methylene-blue absorption band can sometimes also be made out.

[5] At all events I find that chloroform when added to an aqueous solution of the purple sweets (from the third case mentioned previously) remains uncoloured, though it takes on a mauve or purple colour when shaken up with an aqueous [illegible] of ordinary methylene blue. Yet the green urine obtained by eating these sweets gives the characteristic blue colour to chloroform just as does any green urine from the medicinal use of methylene blue. However, on dissolving some of these sweets in a glass of urine and adding chloroform the latter at once becomes blue.

[6] I am indebted to Mr J. Good of Stockport for an example of such urine. It was from an old lady aged [illegible] years who said that it was bright green when voided and that she had never noticed her urine of that colour before [illegible] wards it still had [illegible] decomposing and [illegible] could be seen under the microscope [illegible] crystals. A [illegible] Chloroform shaken up with the sediment took on a faint blue colouration. This was best seen after heating and evaporating off part of the chloroform and then by spectroscopic examination the characteristic absorption band of indigo blue was observed. This case is of course not the one described by Mr Good in THE LANCET of June 1st (p. 1535) and August 31st (p. [illegible]), in which he found after all that the colour of the urine was due to methylene blue.

[7] Achard and Castaigne, loc. cit.

colourless chromogen—that is to say, in its reduced form. Dr. L. Hill has made use of the dye to show how oxygen is used up by cerebral work, the methylene blue being reduced and decolourised by the activity of the brain substance.

Naturally the decolourisation of green urine beginning to ferment may be delayed or prevented by boiling it or adding glacial acetic acid, or chloroform, or any antiseptic preservative substances. The following experiment well illustrates the action of living organisms on methylene blue. If to a weak solution of sugar coloured by methylene blue a little yeast is added the blue colour gradually disappears from the lower layers of the liquid as fermentation progresses. When the sugar is used up fermentation ceases and the blue colour returns, because the yeast cells though still alive have nothing to do. When, however, fresh sugar is added the yeast cells regain their activity and reduce the methylene blue to the state of a colourless chromogen.

The question of green urine from eating coloured sweets is not without its practical importance, for a suspicion of the true cause may save a good deal of time and possibly some anxiety. A medical man when he prescribes methylene blue should not forget, for obvious reasons, to warn the patient of the effect of the drug on the urine, and vendors of sweets, as they can hardly converse with their customers on urinary topics, ought certainly never to sell any sweets containing the colouring matter in question.

Though fuchsin, when given as medicine—as it frequently was some years back for renal affections—quickly reddens the urine I have never heard of a case in which the urine has been thus coloured from eating red sweets. Probably, therefore, fuchsin is not employed as one of the substitutes for cochineal. An eosin-like anilin dye is, however, sometimes employed for sweets. In 1898 the urine of a child just admitted to the German Hospital was found to be markedly fluorescent, somewhat like a weak solution of eosin, appearing pink by transmitted light and golden green when viewed against a black background. About three days after admission the urine was slightly acid and of specific gravity 1020 and still looked greenish-yellow against a black background, though the pink colour by transmitted light had disappeared. Dr. A. E. Garrod kindly told me of a similar case from eating anilin-dyed sweets and I obtained samples of coloured sweets which the child had partaken of just before admission to the hospital. Amongst them were pink discs like "musk-drops" or "rose-drops," and these when dissolved in water yielded a solution fluorescent like the child's urine. The child had doubtless eaten very many of the sweets, for a few only seem not to colour the urine. This is probably why similar urine is seldom observed.

Harley-street, W.

TWO CASES OF BLACKWATER FEVER.

By FREDERICK SMITH, L.R.C.P. & S. IREL.,
CAPTAIN, R.A.M.C.

With Pathological Notes by

M. LOGAN TAYLOR, M.B., CH.B. GLASG.,
OF THE LIVERPOOL MALARIAL COMMISSION; LATE ASSISTANT TO PROFESSOR OF PATHOLOGY, GLASGOW UNIVERSITY.

THE paucity of complete post-mortem records of cases of the little-understood disease, blackwater fever, clinically observed from beginning to end, justifies, it is thought, the publication of this paper.

CASE 1.—The patient was a European who had been for over a year in Sierra Leone doing duty as a non-commissioned officer. He was an exceptionally robust and energetic man. He had not been on the sick-list during his tour, but said that he had "had a couple of hours' fever" occasionally. However, he was seen on the morning of the first day of his illness looking well, smoking, and getting about his work. At 3 P.M. he felt ill, shivered a little, vomited, had a pain in his back, and by tea-time he was passing hæmoglobinuric urine of the usual character. He stated that he had taken five grains of quinine three or four times a week. Next morning he passed about a pint of similar urine. The backache was now agonising and green bilious vomit was frequent. No more urine of any kind was passed for three days. Then he passed in two instalments five ounces containing albumin and none for another three days. The day before his death 12 ounces were removed by catheter in the morning and two ounces in the evening. It contained very little albumin. No hæmoglobin was apparent in the urine after the second day of illness. Jaundice was noticeable within a few hours of the onset of the disease and was intense by the third day. Repeated examinations failed to demonstrate malarial organisms in the blood. Treatment was with boric acid and arsenic—also, of course, symptomatically. During the last four days of illness I (F. S.) made intravenous injections of normal salt solution ranging from half a pint to one and a half pints twice a day by means of an irrigator and an aspirating needle, with a slight temporary good effect on the skin and perhaps the pulse. Life was sustained mainly by nutrient enemata, almost everything given by the mouth being ejected. Vomiting, in spite of all treatment, remained persistent, the matter brought up being progressively darker until it attained a deep mahogany colour. Meantime, the jaundice became less marked and had almost gone before death. The mind was confused about the fourth day, but more or less mental clearness remained to the last, and the patient conversed intelligibly the night preceding his death. Hiccough was troublesome from time to time and there were twitchings of the fingers. The mouth during the last few days was much inflamed and there were hæmorrhages from the buccal mucous membrane. The saliva was blood-tinged and mingled with material of the same mahogany colour as the vomit. Sleeplessness was troublesome only for the first three days. The stools were scanty and loose, naturally bile-stained in colour, but containing no blood. The recorded temperature was never above 101° F., but the temperature commonly dropped with the appearance of the hæmoglobinous urine and it was in this case not taken before owing to the sudden onset. Death took place on the tenth day.

Dr. Taylor made daily blood counts with the following results. On July 24th, the first day of illness, no count was made. On the following dates the number of the red and white blood corpuscles per cubic millimetre was as follows: 25th, red 1,900,000 (24 hours after onset), white 10,000; 26th, red 1,700,000, white 10,000; 27th, red 1,000,000; 28th, red 900,000; 29th, red 1,100,000, white 18,000 (increase chiefly polynuclear); 30th, red 1,000,000; and 31st, red 1,200,000, white 10,000. On August 1st no count was made. On the 2nd death occurred.

Necropsy.—At the post-mortem examination the body was found to be that of a fairly muscular man. The skin and conjunctivæ were of a pale lemon-yellow tint. The lips and teeth were covered with sordes. On examination of the thorax the heart was found to be of normal size and weight. There was marked fatty infiltration of the wall of the right ventricle The heart muscle was pale in colour and was very soft and friable, and beneath the endocardium of both ventricles there was a yellowish mottling which was most distinctly seen on the papillary muscles and was due to fatty degeneration of the muscle. The cavities of the heart were of normal size and with the exception of slight dilatation of the mitral and tricuspid orifices the valvular apparatus was healthy. The aorta was also quite healthy. The lungs were free from adhesions and showed only slight hypostatic congestion and œdema at their bases. The peritoneum was normal in appearance and there was no fluid in the abdominal cavity. The spleen was firm and was considerably enlarged, weighing nine ounces, and the capsule was adherent to the surrounding parts. It was very much congested, but the pulp was not at all diffluent and it was more of a walnut colour than is usually found in a simple congested spleen. The Malpighian bodies were slightly swollen and the trabeculæ were thickened. Microscopical examination of films made from the pulp showed that this walnut colour was due to a large amount of blood pigment. Great numbers of degenerated red corpuscles were also seen. The liver was enlarged, weighing 4 pounds 13 ounces, and was very soft. It was much congested and on section it presented a colour similar to that of the spleen pulp; there was also a yellowish mottling throughout which was due to fatty degeneration. The gall-bladder was distended with coagulated bile. The weight of the kidneys without their intimate capsules was—right nine ounces, left eight and a half ounces. Both presented a similar appearance, so that the one description will do for both. The cortex was enlarged and swollen, measuring fully three-quarters of an inch. Both cortex and inter-pyramidal cortex were of the same walnut colour as that of the spleen and liver but with yellow markings throughout, more especially in the region of the convoluted tubules. The cortical vessels were much congested and there were numerous hæmorrhages around them. The pyramids were of a purple colour and were similarly congested. The larger vessels of the kidneys appeared to be healthy. There were no hæmorrhages in the pelves of the kidneys. The pathological condition was apparently that of an acute catarrhal nephritis. The stomach contained a quantity of bile-stained fluid and some curdled milk. The entire mucous membrane was of a deep red colour which was partly due to extreme congestion and partly to numerous sub-mucous hæmorrhages. The duodenum presented an exactly similar condition with also a certain amount of granularity of the surface, but there was no ulceration. Throughout the small intestine sub-mucous hæmorrhages were present with intervals of six or seven inches between the right down to the ileo-cæcal valve. The mucous membrane of the large intestine, however, appeared to be normal, there being no hæmorrhages present. The mesenteric glands were not enlarged. The bladder was quite collapsed and contained no urine. The head was not opened.

Apart from the standing question as to whether "blackwater" fever is a disease of itself it is desired to be known if the condition of the kidneys in these cases is such as to cause a mechanical suppression, especially in view of the fact that such urine as may be passed is sometimes only slightly albuminous. Steps have been taken for the further investigation of the histo-pathological condition of the organs.

CASE 2.—The second case—that of a West Indian negro soldier—occurred about the same time in the same barracks and the symptoms were much the same throughout except that jaundice was not appreciable and there was not any hæmoglobinuria. There was, however, intense albuminuria and for two days suppression with vomiting and hiccough. Ring parasites in small numbers were found in the blood on the third day of illness and after the man had been taking quinine, but they were not seen on any other day. From the first to the seventh day the temperature varied between 103·2° and 98°F. On the seventh, eighth, and ninth days it was normal, but on the evening of the tenth day it rose to 100·4°, from which point, with intermissions, it rose to 103°, when death occurred on the seventeenth day.

The patient made an apparent recovery; urine was passed in full amount and was, especially towards the end, only faintly albuminous. He was, however, depressed and hysterical and was therefore transferred to the hills—half an hour's journey in a hammock—for change. But the improvement was temporary only, the man complained of great weakness, the temperature rose, slight hypostatic congestion of the bases of both lungs was noticed, and death took place on the seventeenth day of illness. Towards the end this patient had diarrhœa—a symptom which has been present early or late in the course of two or three other cases which have come under my notice. The post-mortem examination made the cause of this diarrhœa clear.

Necropsy.—The post-mortem appearances were almost identical in this case, which (as far as could be judged with the naked eye, at any rate) was not hæmoglobinuric, with those in the first case, which was markedly hæmoglobinuric, only that they were more advanced, especially in the alimentary tract. The condition of the last-mentioned is the most striking feature of the cases and, so far as recent literature goes, at all events, seems to have been taken little or no notice of by other observers. The body was that of a well-built man, but was now much emaciated. There were thrombosis of the left femoral vein with œdema of the leg. The lungs showed only slight hypostatic congestion and œdema at their bases. The heart was of normal size. There was fatty infiltration of the wall of the right ventricle. The heart muscle was very soft and was of a pale yellow colour, this being specially noticeable beneath the endocardium of the ventricles and on the papillary muscle and was due to fatty degeneration of the muscle. Both mitral and tricuspid orifices were slightly dilated, otherwise the valvular apparatus was normal. The aorta also was quite healthy in appearance. The spleen was of normal size, weighing five and a half ounces; it was firmly bound down to the surrounding parts by adhesions. On section numerous abscesses were found in it, altogether about 12 in number, and they varied from about the size of a millet seed to as large as a hazel-nut. Several of the abscesses were just beneath the capsule and at these points the adhesions were very firm. On examining the pus large numbers of bacilli coli were found in it. The spleen pulp was very congested but was quite firm. The Malpighian bodies were rather swollen and the trabeculæ were thickened and prominent. The liver was enlarged, weighing 4 pounds 11 ounces, the enlargement being chiefly of the left lobe. The whole organ was soft and was much congested; on section it presented a deep walnut colour with yellowish markings due to fatty degeneration of the hepatic cells. Each kidney weighed six and a half ounces without its intimate capsules. They were sim[illegible] The whole of the cortex [illegible] of a walnut colour with a [illegible] to fatty degeneration of the renal epithelium. The cortical vessels were much congested and there were numerous [illegible] stomach contained about six ounces of the fluid mixed with bright red blood. The entire mucous membrane was of a dark red colour, being extremely congested, and there were numerous submucous hæmorrhages. The duodenum was in a similar condition to that of the stomach, the mucous membrane being of the same deep red colour, and submucous hæmorrhages were frequent. Some blood was also present in the lumen. Throughout the whole of the small intestine patches of submucous hæmorrhages occurred every few inches. The mucous membrane of the large intestine right down to the rectum was of a uniform bright red colour, being intensely congested. No ulceration was found at all in the alimentary tract. There was no blood in the small intestine beyond the duodenum, the contents being simply bile-stained. The mesenteric glands were considerably enlarged. The bladder contained no urine.

Remarks by DR TAYLOR.—In comparing the post-mortem appearances in these two cases the great similarity between them is at once apparent—in fact, the one description might almost serve for both. As far as one could tell from naked-eye examination the state of the liver and kidneys was the same in both cases. The presence of abscesses in the spleen in Case 2 must have been caused by absorption of organisms from the intestine. Both spleens contained blood pigment and many degenerated red corpuscles, though these were most marked in Case 1. The great disturbance of the alimentary tract during life in blackwater fever is easily accounted for by the condition of the stomach and intestine found after death, and a similar condition may in all probability be found in some of the other tropical fevers where gastric and intestinal disturbances are of such frequent occurrence. The various tissues have been sent home to get sections made and a report on their histological appearances will be made at a future date.

Both of these cases were under my personal care, but I (F.S.) am indebted to Lieutenant S. B Smith, R A.M.C., of Mount Aureol Hospital, for clinical notes of the latter days in the second case, and he performed the post-mortem examination with Dr. Taylor and myself.

Sierra Leone.

THE PHARMACOLOGY OF PYRACONITINE AND METHYLBENZACONINE CONSIDERED IN RELATION TO THEIR CHEMICAL CONSTITUTION.[1]

BY J. THEODORE CASH, M D. EDIN., F.R.S.,
REGIUS PROFESSOR OF MATERIA MEDICA IN THE UNIVERSITY OF ABERDEEN;

AND

WYNDHAM R. DUNSTAN, M.A., F.R.S.,
DIRECTOR OF THE SCIENTIFIC DEPARTMENT OF THE IMPERIAL INSTITUTE.

IN a previous paper[2] we have shown that an entire change in the physiological action ensues on the withdrawal of the acetyl group from aconitine as is seen in the action of benzaconine, the first hydrolytic product of aconitine, from which it differs in containing an atom of hydrogen in the place of one acetyl group. This alkaloid is devoid of the characteristic physiological action and extraordinary toxicity of aconitine, whilst in respect of its action on the heart it is in the main antagonistic to that of the parent alkaloid. In order to study further the remarkable dependence of the physiological action on the presence of the acetyl group we have examined the action of two derivatives of aconitine which we have obtained in this research—viz., pyraconitine and methylbenzaconine.

---

[1] Abstract of a paper read before the Royal Society on June 20th, 1901.

[2] Philosophical Transactions, 1898, pp. 190, 239.

Pyraconitine was first prepared by one of us[3] by heating aconitine at its melting point, when the acetyl group is expelled as one molecule of acetic acid and the alkaloid pyraconitine remains. This compound therefore differs in composition from aconitine by the loss of one molecule of acetic acid and from benzaconine by one molecule of water.

Methylbenzaconine was obtained from aconitine by heating it with methyl alcohol in a closed tube.[4] A remarkable reaction takes place, in which the acetyl group is ejected as acetic acid, a methyl group taking its place. This alkaloid therefore differs from aconitine in containing a methyl group in the place of the acetyl group, and from benzaconine in containing a methyl group in the place of one atom of hydrogen. *The examination of its physiological action would therefore* be the means of studying the result of replacing in aconitine the negative radical acetyl by the positive methyl group and also of studying the effect of the introduction of methyl in modifying the physiological action of benzaconine.

The acetyl group of aconitine evidently occupies an exceptional position in the molecule of aconitine. So far as we are aware it is the only acetyl compound at present known which exchanges this group for methyl when it is heated with methyl alcohol. We have examined the behaviour of numbers of different types of acetyl derivatives from this point of view and can find none analogous to aconitine. For the study of their physiological action these alkaloids have been specially purified and employed as hydrobromides in aqueous solution.

Contrasting the physiological action of pyraconitine with that of aconitine, as described in the present paper, we find, as might be anticipated from our previous results, that through the removal of the acetyl group the great toxicity of aconitine is nearly entirely abolished and the characteristic features of aconitine poisoning are no longer produced by pyraconitine.

Contrasting the physiological actions of benzaconine and pyraconitine which differ from each other empirically by one molecule of water, pyraconitine, the anhydride, is the more active compound. Both these alkaloids, divested of the acetyl group of aconitine, are relatively weak and feebly toxic when compared with the parent alkaloid.

Although benzaconine and pyraconine exhibit a strong similarity in the physiological effects which they produce, there are differences between them which are probably more considerable than they would be if pyraconitine were merely the anhydride of benzaconine.

The substitution in aconitine of methyl for acetyl which occurs in the formation of methyl benzaconine has led to a very considerable reduction in toxicity and has introduced a curare-like effect similar to that first observed by Crum Brown and Fraser[5] to result from the introduction of methyl into the molecule of an alkaloid. Methyl benzaconine is however more toxic and generally more powerful than benzaconine, owing to the presence of the methyl group.

Action of pyraconitine.—The main effects of pyraconitine may be thus summarised. Its local application is devoid of the effects characteristic of the aconitines. Its chief action upon the heart is to cause slowing, partly from vagus irritation, partly from depression in function of intrinsic rhythmical and motor mechanisms. There is less tendency to want of sequence in the cardiac chamber walls than is observed *after the aconitines and benzaconine.* The vagus apparatus remains active in degree after doses somewhat in excess of the lethal, the slowed heart of pyraconitine being accelerated both by vagotomy and by atropine. Activity of respiration is reduced (by central depression) to a degree incompatible with life, as is the case after aconitine and benzaconine. The peripheral motor nerves and muscular tissues are not at this time markedly affected. Artificial respiration prolongs life, but the slowed heart and greatly reduced blood-pressure tend to a fatal issue. The spinal cord is impaired in its reflex function, apparently secondarily to reduced circulation in its structure. A tendency to tonic spasm in frogs is late in appearing and of moderate degree. It has not been seen after destruction of brain and medulla. It is further associated with a curious condition of exaggerated motility. Neither muscular nor intra-muscular nervous tissue is strongly influenced by pyraconitine in lethal or somewhat hyper-lethal doses. The lethal dose per kilogramme frog's weight is practically about 12 times tha which is lethal per kilogramme rabbit's weight.

Contrasted effects of pyraconitine and benzaconine.—O these two alkaloids pyraconitine is approximately six t seven times more toxic towards mammals (rabbits an *guinea-pigs)* than is benzaconine, *and* five to *six* times mor so towards frogs. They are alike in their action upo mammals, in so far as they are non-irritant, that they slo the respiration without preliminary acceleration, that the slow the heart and reduce the blood-pressure to a very lo level, that they cause paresis and in guinea-pigs clonic movements, and that respiratory failure is the immediate cause o death. They differ in so far that pyraconitine acts mor rapidly, but for a shorter period, whilst the fatal terminatio *of poisoning is preceded by convulsions, which are very rar* after benzaconine. Benzaconine alters the sequence of th ventricles upon the auricles much more usually and to a greate extent than pyraconitine, though if a sequence is develope it has the same general character (the auricular second bea being blocked from the ventricle). Whilst pyraconitin stimulates the cardiac vagus both centrally and within th heart (section and atropine causing acceleration), and finall occasions only a limited reduction in its activity, benzaconin produces but little stimulation and ultimately suspends th vagus inhibitory action. Under these conditions atropine is of course, inoperative. Both accelerate the heart in small but slow it in large, dose, and both may disorder the sequence but vagus inhibition is much more interfered with by benzaconine. Frogs poisoned by benzaconine lose the power o voluntary movement, then reflex disappears, and finally th circulation is arrested; but after pyraconitine reflex outlast the heart's action. Late spasm occurs after the latter, no after the former. Whilst in lethal doses pyraconitine has n effect beyond somewhat favouring fatigue and reducin excitability of motor nerves, benzaconine greatly impair their function and in thorough poisoning may suspend i entirely.

Action of methylbenzaconine.—The action of methylbenzaconine may be summed up as follows. It is very feebl in its toxicity when contrasted with aconitine, but is somewhat stronger than benzaconine. Small and medium doses, whilst slowing the heart, do not cause any failure in sequence, but larger doses have this effect. They act upon the rhythm of the organ, involving the movement of the auricle and ventricle whilst ultimately the sequence of the latter upon the former is impaired, so that it follows only a certain proportion of the auricular "leads." This block is not removed by atropine. Whilst the passage of the ventricle into diastole is at first retarded, the contractile power of the myocardium is ultimately reduced by methylbenzaconine. The cardiac vagus is depressed in action and its inhibitory function is ultimately suspended by large doses, neither section of the vagus nor atropine administration relieving the slow and faulty action of the organ. There is evidence of slight primary stimulation of reflex cord centres when ligature of vessels prevents the masking of this condition by the peripheral action of the poison. The subsequent impairment in cord reflexes is later in occurring and of much shorter duration than the action of methylbenzaconine upon intra muscular motor nerves. In mammals the paralytic symptoms are predominant; the fall of temperature is in part attributable to this cause as well as to changes in the circulation. The clonic movement *and salivation (observed in* a certain stage of the action of methylbenzaconine, especially upon guinea-pigs) are suggestive of the action of a near ally of aconitine In frogs, however, there is no semblance to an aconitine effect, unless its very feeble action towards sensory nerves or its much more powerful action upon motor nerves be thus viewed. Motor nerves are greatly affected by doses which are distinctly below the lethal for cold-blooded animals, the action being curare-like in character. Muscular tissue is, after the action of large doses, more susceptible of fatiguing influences. Fibrillation in muscles to which the poison has access is more common than after aconitine or any other derivative examined. These observations support in the main the contention of

Dunstan and Carr: Transactions of the Chemical Society, 1894, vol. lxv., p. 176.

[4] Proceedings of the Chemical Society, 1896, p. 159.

Transactions of the Royal Society of Edinburgh, 1869, vol. xxv., p. 192.

Crum Brown with Fraser that the introduction of methyl into the molecule of certain spasm-producing alkaloids masks the effect of these by occasioning a curare-like action at the periphery

Contrasted effects of methylbenzaconine and aconitine —The toxicity of aconitine is, roughly, from 80 to 100 times that of methylbenzaconine towards rabbits and guinea-pigs and much the same proportion holds for summer and winter frogs respectively Whilst slight tendency to salivation and retching movements are produced by methylbenzaconine, and are in so far suggestive of a slight aconitine action, the absence of initial acceleration of respiration, of local irritation, and dyspnœal convulsions and the predominance of paralytic symptoms, are points of difference The action upon the heart is entirely distinct for the pulse is slowed by methylbenzaconine, the auricles eventually beating more rapidly than the ventricles, the action of the poison proceeds uniformly and without the intermissions which characterise aconitine, whilst the early phenomena of vagus stimulation have little in common The general symptoms of poisoning in frogs have scarcely a point of similarity, quiescence, rapid failure of reflex and voluntary movement without impairment of the cardiac action, being distinctive of methyl benzaconine, whilst excitement with great motility and persistence of voluntary movement follow aconitine Fibrillation is much more pronounced after the former, though it is only a transitory phenomenon. The action on the heart differs widely in frogs as it does in mammals whilst the curare like action of the derivative on motor nerves is not produced by aconitine in doses which just suffice to arrest the heart It is true that large but sub lethal doses of aconitine are followed by a condition of almost complete paralysis which lasts for several days, but during this time there is slight voluntary and reflex movement the nerve endings are not put out of action and the circulation is usually of the feeblest character, all conditions which are not found in the period of quiescence following methyl benzaconine

Contrasted effects of methylbenzaconine and benzaconine —Methylbenzaconine is from three to four times more toxic towards rabbits and guinea pigs than benzaconine and from twice to thrice as toxic towards frogs (*Rana temporaria* and *Rana esculentus*) In mammals, slight salivation, retching movements, and muscular tremor are characteristic effects of the former, but dyspnœa ataxia, and paresis are also seen after benzaconine Of the two, methylbenzaconine is distinctly less depressant towards the heart. Slowing of the pulse and want of sequence of ventricular upon auricular action occurs after both, but is a much earlier symptom after benzaconine, which causes more disorder in the motor mechanism On the other hand the intra cardiac vagus is put out of function more readily by methylbenzaconine Death after either poison is rarely preceded by spasm Neither of the two compounds causes any local irritation in frogs, but methylbenzaconine produces active fibrillation in the muscles, to which it gains access and develops a complete curare-like action much more prominently than does benzaconine, the heart continuing to beat strongly Benzaconine, in dose sufficient to cause such an effect at the periphery, acts disastrously upon the circulation In partial poisoning by methylbenzaconine the characteristic rapid failure of the intra muscular motor nerves on stimulation is well marked, but the subsequent recovery on resting so characteristic of benzaconine, has not been observed

CONGENITAL SPONTANEOUS GANGRENE

BY C E RICHMOND, F R C S Eng ,

HONORARY SURGEON TO THE WARRINGTON INFIRMARY

THE report of Dr Armstrong Bowes's case of spontaneous gangrene in an infant in THE LANCET of August 31st 1901, p 686, leads me to publish the following case

In May, 1898 I saw in consultation with my friend Mr D C M Hunt of Lymm a case of which I herewith give a *verbatim* rescript from my case book

"Girl baby One week old Nature of case acute inflammatory gangrene (congenital) Date, May 3rd 1898 Mother had one previous confinement (premature) This one at full term Labour natural with slight delay after delivery of head *When born* child showed two areas of acute dusky inflammatory redness, one just below occiput, the other over and around the seventh cervical vertebra Redness also on scalp Three days after birth upper area sloughed (without any black patch) Black patch—i e , gangrenous slough—formed in centre of lower inflamed area When seen by me (May 3rd) black slough was separating and dull dusky redness extended down back and across neck. On site of upper area of redness was simple 'atonic' ulceration the size of a florin and some superficial 'weeping' sloughs on scalp (atonic ulcerations) May 5th Area of redness extended round scalp and chest still duskily and passively congested. Condition worse Black slough separated over back of neck, leaving somewhat brawny, dry looking surface Same appearance on occiput Superficial skin necrosis extending on scalp General dulness and tendency towards torpor Internal strabismus has supervened (query indication of central cerebral mischief of which superficial gangrene is trophic evidence? or pseudo-ptomaine infection of nerve-centres due to septic absorption from sloughs &c ?) Prognosis as bad as possible May 8th Patient died No p m No evidence or history of syphilis

The foregoing is a literal transcript of my notes of the case taken in my case book at the time I may say that at the first visit I unhesitatingly gave a fatal prognosis to the parents which was only too soon verified though the child at the time seemed to be in fair health On thinking the matter over I am entirely of opinion that the lesion was trophic from nerve central mischief and not from any septic lesion absorption That this central mischief preceded birth is evidenced by the peculiar nature of the diseased areas and the fact that they existed at birth I think I used the correct term when I described the process as acute inflammatory gangrene The pathology of such a condition must necessarily be obscure I confess to not being well acquainted with the literature of such cases but whether they occur intra uterine or at some period subsequently to birth they point I think to a community of origin and that a central nerve one in the onset The strabismus would favour this view as also would the grave constitutional effects out of all proportion with the local lesions These lesions I think from their character to be distinctive evidence of trophic deficiency for which no local cause can be adequately assigned If a local cause plays any part it is that of injury—slight probably—to an area of already deficient trophic vitality

I have never practised midwifery and therefore my opportunities of observing the newly-born are not very extensive My memory holds two similar cases though I have only notes of this one The parents in this case were well to-do but I am of opinion that amongst the poorer classes such cases will be found to be of much more frequent occurrence as probably experienced obstetric practitioners can testify

Warrington

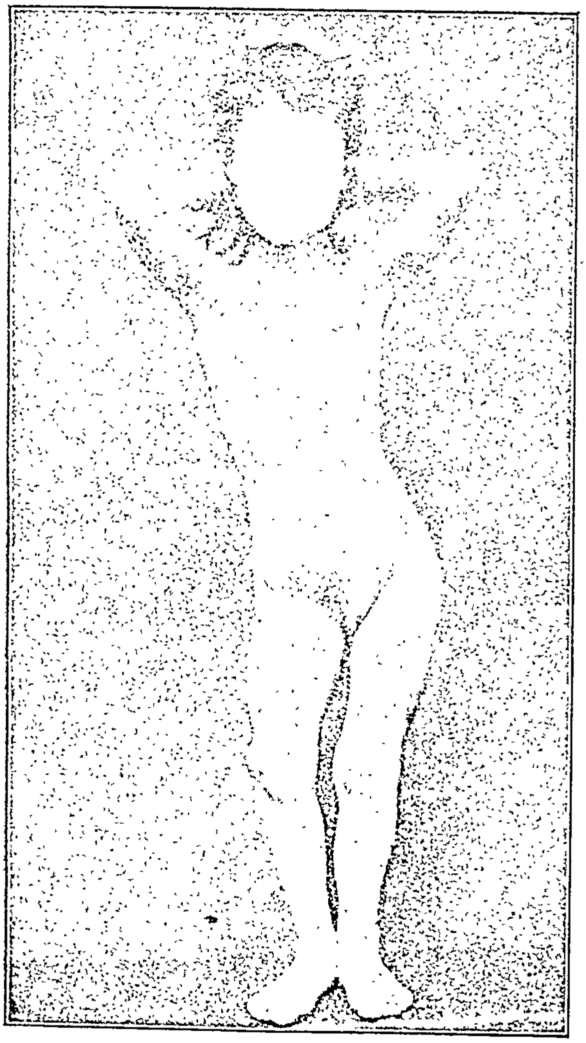
ADDED MILK IN BUTTER —At the South-Western Police-court London, on Sept 12th Messrs Pearks, Gunston and Tee grocers were summoned at the instance of the Wandsworth Borough Council for selling butter which contained an amount of moisture 6 5 per cent above the accepted standard of 16 per cent The basis of this butter was colonial butter—a particularly dry article which the defendants first softened and then incorporated in a mixer with a certain proportion of added milk It was said that about 500 tons of this butter were produced weekly and it was sold with a label which contained the words, "This choicest butter, blended with pure English full cream milk by new and improved machinery whereby it retains about 20 to 23 per cent. of moisture and acquires that delicacy of flavour which has made Pearks's butter so famous" Counsel for the defence submitted that by the label the purchaser was informed of the nature of what he was buying and therefore was in no way deceived The magistrate in giving judgment found firstly that the object of the defendants was to introduce additional moisture and so increase the bulk weight or measure of the butter and secondly that the addition was made fraudulently He inflicted a penalty of £10 with £5 5s costs and gave permission to have a case stated. The same defendants were for a precisely similar offence fined £20 at Peterborough on Sept 10th and £20 and £5 5s costs at Wellingborough on Sept 13th at the instance of the Northamptonshire County Council

A CASE OF DEFORMITY ARISING FROM ARRESTED GROWTH IN ONE LIMB REMEDIED BY EXSECTION OF BONE FROM THE OTHER.

BY G. P. NEWBOLT, M.B. DURH., F.R.C.S. ENG.,
HONORARY SURGEON TO THE ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

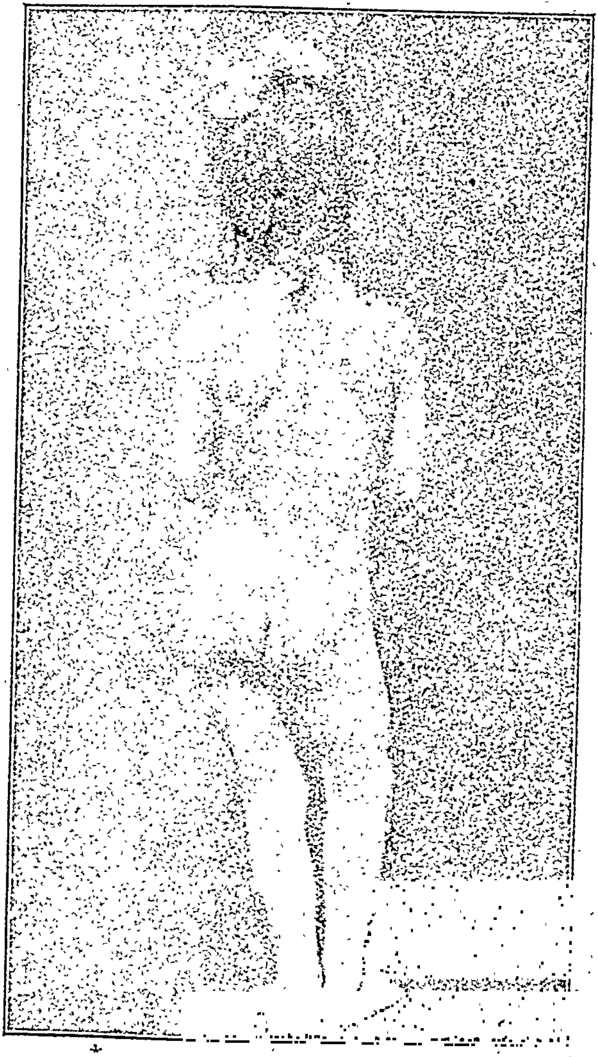
A GIRL, aged 11 years, was admitted to the Royal Southern Hospital under my care on May 15th, 1900, suffering from deformity probably the result of rickets. She was an orphan and it was difficult to get a very reliable history, but she was born with a cleft palate which had been closed by operation, and near each knee was the mark of what I took to be an osteotomy wound. On examination there was flexion deformity of both hips. The left leg was two and a quarter inches longer than the right and the limb was adducted very considerably. There was genu varum affecting the right knee and this limb was somewhat abducted. A scar was visible on the inner side of this knee about the level of the upper end of the tibia. The contracted state of the adductors of the left thigh prevented any abduction of this limb without using force. There was lateral curvature of the spine with the convexity to the right most marked in the lumbar region. The right shoulder was higher than the left; the left loin angle was marked; the angle of the left scapula was close to the spine and the right some way from it. There was also a prominent left hip, so that altogether the child was much deformed, as Fig. 1 and Fig. 2 show. In order to walk she adducted the left thigh and flexed both hip and knee; she also abducted the right leg and flexed the right hip.

FIG. 1.



Before operation. Front view.

FIG. 2.



Before operation. Back view.

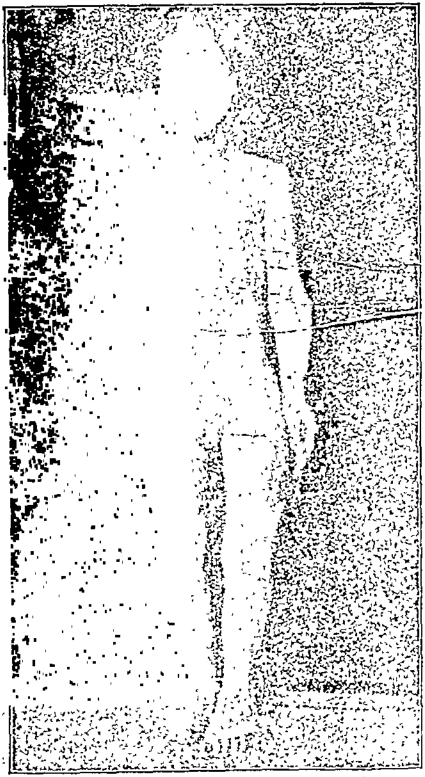
The measurements were as follows. Height: three feet six inches; normally it should have been four feet five and a half inches. Right limb, real length, 18¼ inches; left limb, 20½ inches; difference, two and a quarter inches. Right limb, apparent length, 21 inches; left limb, 22½ inches; difference, one and a half inches. The right femur measured nine inches and the left 11¼ inches, so that the difference occurred in this bone. There were about 15° of flexion deformity in the left hip and a little less in the right.

On May 29th, 1900, I sawed through the right femur above the condyles and corrected the deformity, putting good extension on the limb. At the same time I forcibly corrected the flexion at the hips and overcame the adduction. When she had recovered from the operation I found that by putting a couple of inches under the right foot the child was fairly straight.

On July 24th, 1900, I cut down on the left femur from the outer side, making a four-inch incision; having exposed the periosteum I separated it from the bone and tied all bleeding points. Next I measured off one and three-quarter inches with a wire gauge and bored holes above and below the part I intended to remove. With a chain saw passed round the bone I cut out the portion required and then wired the two ends together. The periosteum was sewn over the wire, the separated muscles were sutured, and the wound was closed.

The limb was put up on a Thomas's bed-splint and firmly fixed. The wound had healed and the stitches were removed at the first dressing, two weeks after operation. On Oct. 3rd, about 10 weeks after operation, I allowed the patient to walk, and Fig. 3 and Fig. 4 show her condition in December.

FIG. 3.



After operation. Front view.

On Jan. 5th, 1901, the measurements were as follows. Apparent right, 22 inches; left, 22½ inches; real right, 19½ inches; real left, 20 inches—a difference of half an inch. That is to say, the right limb had grown one and a quarter inches during the last eight months, which is a fair average taking the normal rate as two and a quarter inches per annum for the whole body. Mr. C. T. Holland kindly took an x-ray photograph of the wired bone.

My reasons for not removing the full amount of bone were the following. I feared that the muscles of the thigh might not contract sufficiently and that the knee-joint would be left in a weak and flail-like condition, a thing which I have seen occur occasionally in cases of fracture of the shaft of the femur with much shortening, and I thought that by letting the patient get about fairly early there would be some absorption of the newly-joined ends of the bone, and that this would diminish the superfluous half-inch. Apparently this has not happened, and it points to the fact that patients may get about early on an accurately-adjusted transverse fracture without shortening resulting. It is easy to prove that if in oblique fractures patients walk too soon shortening occurs by measuring the limb some months later.

Some may criticis [illegible] operation and say, Why did you not use a thick boot? [illegible] by the right leg not growing ap [illegible] first place, a surgical boot with two and a quarter inches of cork in it is an expensive luxury, and if once supplied would never have been replaced. If the shortening had gone on it is probable that at least four inches of thickening would have been necessary. Now, if the shortening continues a slight thickening of the heel each year is all that will be needed until the girl is old enough to look after herself and her shoe-leather. As to whether the deformity will recur I am not sure. The shortening is either due to an osteotomy damaging the epiphysis or to arrested growth from rickets. There is a beautiful specimen of the latter condition in St. Bartholomew's Hospital Museum, of which Mr. Keetley gives an illustration in his recent work on Orthopædic Surgery.[1] I am inclined to think that the deformity in my case was due to this condition. Free use of both limbs now that they are fairly equal may end in their remaining so, and up to the present the measurements continue to be satisfactory. One thing is certain, that if no treatment had been adopted the eventual result would have been very marked deformity—i.e., great shortening, incurable adduction of the left limb, deformity of the pelvis, and very marked lateral curvature with rotatory changes in the vertebræ, such as no treatment would have overcome. It seems to me that this operation is applicable to many cases in which one leg is much shorter than the other, such as in cases of old fracture, old excision of the knee with shortening, hip disease with short leg, &c.; in many of these there would not be the objection that subsequent shortening might occur. Judging from the small amount of discomfort which this girl endured, the operation if carefully done is not a severe one and does not compare with that done for a mal-united or un-united fracture of the femur.

SIX CASES OF EXCISION OF THE LARYNX.

By F. G. HARVEY, F.R.C.S. Edin.,
SURGEON TO THE HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN-SQUARE, W.C.

As the recorded cases of complete excision of the larynx are comparatively few, and the details of the method, as far as I know, have not been fully described, I think it may be of interest to publish these cases.

The complete removal of the larynx by the method which aims at cutting the trachea and lungs off completely from the pharyngeal cavity, and obtaining primary union of the parts divided when severing the larynx from its connexions, was, I believe, first described by Rötter, and to him I am mainly indebted. I have not seen his paper, but merely an abstract of it, and I propose now to offer somewhat fuller details of the method, in the hope that it may be of use to those who have not seen the operation or to those who, like myself, have seen no detailed account. I shall follow in the main Rötter's description. I claim no originality, but shall speak a little in detail on some points which have appeared to me to offer practical difficulty.

The operation may be performed by separating the trachea and cricoid cartilage from the œsophagus, commencing from above and working downwards or commencing from below and working upwards. I will describe the latter method. I assume the proper preparation of the patient for a long and serious operation, strict antiseptic precautions, and the proper warming and ventilation of the operating room, with as little exposure of the body as possible.

The first step, after administering chloroform to the patient, is to make a vertical incision extending from the hyoid bone to a point as low as the fourth or fifth ring of the trachea. A transverse cut should be made along the whole length of the under surface of the hyoid bone through skin and fascia, dividing the anterior jugular veins which must be tied. The sterno-hyoid, the omo-hyoid, and the thyro-hyoid muscles are divided at their insertion into the hyoid close to the bone, and the flaps thus formed are reflected downwards and outwards to either side. The thyroid isthmus should then be divided between two ligatures and the lobes of the thyroid separated from the trachea. When the trachea is completely bared it may be divided from before backwards and the lower portion separated from its attachments to the œsophagus and stitched to the skin. A Hahn's cannula will now be introduced, all bleeding will be arrested, and the parts immediately around the lower portion of the severed trachea will be packed with gauze. It will be found necessary to remove the Hahn's cannula from time to time and to clear the trachea of any blood which may have found its way into it. The patient at this point must not be deeply under the influence of the chloroform, as we shall then have warning of any blood trickling into the lungs by his coughing; if this occurs it will be well to sponge out the trachea by introducing for some distance a swab or sponge on a holder. The next step will be to dissect off the upper portion of the trachea from the œsophagus and the muscles from the lateral surface of the cricoid. The inferior cornu of the thyroid is next bared by detaching and reflecting the crico-thyroid and inferior constrictor muscles. The muscles and perichondrium in front of the thyroid will now be separated and reflected as far back as the superior cornu, which latter will next be freed by dividing the periosteum on its surface, and pushing it along with the lateral wall of the pharynx and the loose areolar tissue backwards until the posterior lateral border of the cricoid is reached The outer two-thirds of the lateral portion of the thyro hyoid membrane, which is attached to the superior border of the thyroid cartilage, will then be divided transversely and cautiously at the point of junction of its upper and middle thirds; and when the adjacent mucous membrane is reached this must be picked up with forceps and divided, whereby the upper portion of the epiglottis can be seized and drawn forwards. The anterior wall of the pharynx is thus opened, and by pulling the epiglottis strongly forward and with it the whole larynx the knife can be placed on the posterior surface of the cricoid, and by cutting downwards the anterior wall of the œsophagus will be opened. Care must be taken at this point to limit the cut to the parts which are covered in front by the posterior surface of the cricoid; if this is not done the lateral wall of the pharynx and the œsophagus will be unnecessarily encroached upon and too much of their anterior walls will be removed, thus rendering it difficult to approximate their edges. The whole larynx is thus completely detached, and the defect in the pharyngeal mucous membrane must now be made good by inserting sutures quite close to the cut edges and so preventing in-turning of the epithelial surfaces. The sewing up must be water-tight with fine catgut sutures so as to form a Y-shaped stitched line, then a row of Lembert's sutures must be added transfixing the muscular and cellular coats of the œsophagus and pharynx. The third layer unites the stumps of the pharyngeal constrictors, and the fourth layer brings together the divided sterno-hyoid and thyro-hyoid muscles. Finally the T-shaped skin incision will be united, leaving only a three-cornered cavity above, which may be packed with iodoform gauze; thus, only the above cavity and the tracheotomy will remain unclosed. The Hann's cannula may be removed in 24 hours. Nutriment will be administered by the rectum for from 24 to 48 hours, after which milk may be given by the mouth. Rötter suggests that the trachea should be divided from behind forwards, but it is far more easy, expeditious, and safe to divide it as I have described. I need hardly emphasise the importance of keeping blood out of the lungs, the whole success turning on this point and the accurate suturing of the pharynx and œsophagus. Of the six cases here noted it will be seen that three were treated by this method. Of the remaining three, one was treated by the older method with a preliminary tracheotomy and stitching the pharynx to the skin; the second can hardly be classed as an excision, inasmuch as the whole of the larynx, when the soft parts covering it were reflected, was capable of being lifted off.

Case 1.—A man, aged 49 years, came to the Hospital for Diseases of the Throat on July 17th, 1894. He had been a patient 12 months previously and he was then advised to have his larynx removed but would not consent. When he was admitted on the second occasion the disease was thought to be too far advanced for operative interference and it was only at his urgent solicitation that I consented to make the attempt, after having explained to him that I did not hold out any hope of success. The diagnosis, which was verified by subsequent examination, was that of squamous epithelioma, and the prognosis was one of early asphyxia if the patient were unrelieved by tracheotomy. The method of operating was as follows. A preliminary low tracheotomy was performed some fortnight before the major operation, which latter was done on August 14th. Chloroform was first administered and then the tracheotomy tube was removed and the wound was slightly enlarged. A Hahn's cannula was inserted into the trachea, an incision was made down the front of the neck from the hyoid level to the upper part of the tracheotomy wound, and another incision was made transversely along the under surface of the hyoid bone. The tissues were then dissected off the thyroid and cricoid cartilages. There was a small piece of growth coming through the crico-thyroid membrane. The larynx was removed, leaving a portion of the left thyroid cartilage; the edges of the mucous membrane were stitched to the skin and the transverse incision was closed by sutures. Bleeding was slight and the patient bore the operation well. A soft rubber feeding-tube was put in the œsophagus and fixed. With regard to the after-history the general condition remained good after the operation, the temperature ranging between 98·8° and 99·6° F., the pulse and respiration being about 80 and 19 respectively. A plastic operation was subsequently undertaken to cure the opening in the gullet. The patient has since remained in excellent health, carrying on his duties uninterruptedly, and when seen a few weeks ago his condition was in every way satisfactory. He has an artificial larynx whereby he can speak quite well by closing with his finger the outer opening of the tracheal tube.

Case 2.—The patient was a female, aged 29 years. The diagnosis was that of carcinoma of the larynx. The prognosis was one of early asphyxia if the patient were unrelieved by tracheotomy. The operation was performed on August 22nd, 1894, the method adopted being as follows. A vertical incision in the middle line of the neck from the hyoid to just above the sternal notch and a horizontal incision along the lower border of the hyoid bone were made; the flaps thus formed were reflected downwards and upwards, together with the whole of the soft structures covering the front of the larynx When this was done it was found that the whole of the cartilages of the larynx were so thinned and brittle that the larynx did not admit of being removed in its entirety, but crumbled away piecemeal, even on gentle manipulation When thus removed it was found that the disease had involved, and in a great measure destroyed the anterior wall of the pharynx and upper portion of the œsophagus No vestige of the larynx remained and it was not possible to restore any part of the pharynx by suturing It was with difficulty that the distal end of the œsophagus was reached and secured to the edges of the wound above and behind the trachea. A tracheotomy tube was placed in the trachea at a rather lower level With regard to the after history the patient remained in the hospital for several months and was then transferred to the cancer wards of the Middlesex Hospital where I understand that after a sojourn of some weeks she died the immediate cause being hæmorrhage in the vicinity of the wound

CASE 3 —The patient was a man, aged 64 years Carcinoma of the larynx was diagnosed A few days prior to the operation a tracheotomy had to be hurriedly performed owing to a sudden attack of dyspnœa At the operation which was done on August 22nd 1895, a Hahn's cannula was inserted, the thyroid cartilage was split in the middle line, and *the growth was found to be localised to the right* side The right half of the larynx was entirely removed The operation presented no difficulty With regard to the after history the patient progressed favourably until *the 29th, when during the morning he was somewhat restless* In the evening of the same day, whilst sitting up and without any premonitory symptoms his breathing became embarrassed, he quickly lost consciousness and died *in a few minutes No post mortem examination* was allowed and I am quite unable to account for his death as up to the morning of the day he died no untoward symptoms had manifested themselves

CASE 4 —The patient was a man aged 52 years He was a stout but flabby man who had indulged somewhat freely in alcohol He consulted me in July 1896 He was then suffering from hoarseness, but his breathing at this time was free As regards laryngoscopic appearances the right ventricular band was much swollen and there was an ulcer on the posterior part of the right vocal cord A portion of the growth was removed and was found to be malignant. A few days later his breathing became embarrassed, necessitating tracheotomy As the growth was so extensive I advised him to have the larynx removed but to this he would not consent though not averse to a thyrotomy On August 13th the larynx was split and an extensive growth on both sides was found The ventricular band and nearly the whole of the mucous membrane were removed, the crico thyroid membrane was divided and pure carbolic acid was applied especially to the lower angle of the right ala and cricoid The patient made a good recovery I saw him again in October, when there was a large fungating mass projecting from the interior of the larynx and involving the tracheotomy wound Nothing short of complete excision offered any chance of recovery, so I proceeded on Oct 22nd to remove the larynx commencing from above downwards and finally severing the trachea below the insertion of the tracheotomy tube The skin and muscles some inch and a half around the tracheotomy wound were completely cut away and the cervical glands were removed from the sheath of the jugular vein in the lower part of the neck He made an uninterrupted recovery, *taking milk by the mouth in 36 hours* Six weeks later it was found necessary to remove another gland on the opposite side of the neck. In January 1897 there was a recurrence of the growth in the neck involving *the sterno mastoid muscle on the right which was deemed* too extensive for removal The patient gradually sank and died from asthenia, the growth having involved the neck and thorax, but the trachea remained free and there was no dyspnœa. This case appeared to be of an unusually malignant nature and it is much to be regretted that the patient did not submit in the first instance to a complete excision of the parts

CASE 5 —The patient was a man aged 61 years Tracheotomy was performed in May 1897, for the relief of dyspnœa On Oct 8th he was found to be almost voiceless and unable to rest at night owing to frequent blocking of the tube with thick and blood stained phlegm The laryngoscopic appearances were as follows There was a large swelling on the left side of the epiglottis The ary-epiglottic fold ventricular band and adjoining parts were involved in the infiltration There were marked irregular isolated nodules on the epiglottis the right arytenoid was red and [illegible] to sight and touch, and the [illegible] One gland was enlarged [illegible] side At the operation, on the 12th the growth was found to have perforated the crico thyroid membrane on the left side and the sterno-hyoid muscle was found to be infiltrated as far up as the hyoid. The excision was commenced from the upper end and the tracheotomy wound was not interfered with until the final severance of the larynx from its connexions The piece of the hyoid to which the muscle was attached was cut away with bone forceps The wound was dressed with boric lint kept constantly wet At the expiration of 24 hours the patient was able to take milk by the mouth On the 23rd there was a slight leakage of milk through the wound It was deemed [illegible] gical tube for a fe[illegible] taking food [illegible] recovery As regards his after history, he gained some 2 stones in weight and remained in excellent health for a twelvemonth when he had an attack of acute pneumonia and died in a few days There was no sign of any recurrence of the disease

CASE 6 *The patient was a man aged 48 years* On admission to the hospital he was seen to be a big man but not in good condition The heart was slightly enlarged the pulse was regular the lungs had moist sounds at *their bases and the liver was not enlarged* The urine was acid its specific gravity being 1030 with no albumin or sugar He could only take fluids but had no pain As regards the laryngoscopic appearances there was a sessile growth of the size of a large bean situated on an infiltrated base just below the right aryteno epiglottidean fold and running obliquely down over the ventricular band and hiding the anterior two thirds of the vocal cord The right side of the larynx was fixed and the posterior third of the vocal cord which alone was visible was seen to be motionless and white The left side of the larynx and the vocal cord moved freely A piece of the growth was removed and examined microscopically the diagnosis of epithelioma being confirmed There was an indefinite thickening on the right side of the neck opposite the level of the thyroid cartilage (?enlarged gland) The respiration was comfortable although there did not seem to be very much room The voice was hoarse The history was that until six months before his admission to the hospital the patient had never had any trouble with the throat. About that time he had a little difficulty in swallowing and a feeling of gurgling in the throat *About two months before the operation he had* pneumonia the temperature reaching 105° F and he suffered from great dyspnœa so much so that tracheotomy was contemplated During the next two months he was hoarse on and off *gradually getting worse* and there was increased difficulty in swallowing, the cough was often severe with much phlegm in the throat and occasional slight earache He could swallow solids until two days before his admission He had been a heavy smoker and also drank freely had suffered from winter cough and there had been lately some wasting There was a specific history 25 years before He had been taking iodide of potassium without any benefit On July 23th 1900 I excised the larynx and then found that on the right side at the level of the inferior cornu of the thyroid the growth had perforated into the neck through the posterior part of the crico thyroid membrane As regards the after history his health was good and his condition satisfactory up to the following December when he presented himself for examination An enlarged gland was found and removed from the sheath of the jugular vein above the level of the great cornu of the hyoid *bone on the right side* He has now a Gluck's artificial larynx whereby a loud whisper can be produced and conversation can be carried on and his health appears to be quite satisfactory

Cavendish place W

POISONING BY CARBOLIC ACID —At Redditch on Sept 11th a man was accidentally poisoned by carbolic acid being given to him *instead* of some medicine which he was taking for a cold Death took place in 20 minutes before medical assistance could be obtained The carbolic acid was intended [illegible] *the medicine*

THE LOCALISATION OF FOREIGN BODIES BY THE X RAYS.

BY WILLIAM R. FOX, L.R.C.S., L.R.C.P. EDIN.,
HONORARY PHYSICIAN TO THE MELBOURNE BENEVOLENT ASYLUM.

THE localisation of foreign bodies by means of the x rays has been the subject of much study since the introduction of this valuable adjunct to surgery generally. It was, of course, soon recognised that x-ray photographs were merely photographs of shadows and hence were liable to all the distortion and exaggeration which are so essentially a shadow's characteristics. To eliminate these sources of error in estimating the position of some object deeply buried in the tissues of the human body several very ingenious contrivances have been brought under the notice of the profession, notable amongst them being the Dennis fluorometer of the Rochester Fluorometer Company of Rochester, New York.[1] the localiser of Professor Rémy of Paris, and the method of Mr. Barrel of Bristol,[2] and that of Professor Waymouth Reid of Dundee.[3] Careful consideration of these and other instruments for a similar purpose will enable one to discover that the *underlying principle is the same* in each, and that it is the only principle yet brought forward which, when properly used, will completely eliminate error. The first step in the localisation of an object is to determine definitely the position of a plane or section of the body in which that object lies; the second is to determine accurately the position of a second and separate plane in which it also lies. Now since the object lies in both these planes it can only lie in that part of each of them which is common to both—namely, their intersection. Now the intersection of two planes is a straight line, hence the object whose position is to be determined must lie on this line, and it is then only necessary to get a measurement from either end of this line, or measurements from both ends of it, to determine accurately the position of the object. This may be well illustrated by taking two small sheets of cardboard or stiff paper, and making a slit or cut in each from the mid-point of one side half way across to the other side, keeping the cut equidistant from each end, and then sliding the uncut half of the mid-line of each sheet into the cut or slit portion of the other, the sheets being at right angles to each other. These two sheets of paper or cardboard then represent the two planes mentioned above and it will be seen that their intersection is a straight line and that a measurement from either end would absolutely fix the position of any particular point on this line To ensure absolute accuracy in taking the x-ray photographs these planes must be at right angles to each other, but the error resulting from a small deviation from the rectangular position, unless over large areas, is so small that it may be neglected. Now, the method to be described of applying this principle to practical purposes has the great merit of being so simple that anyone can easily master it; instead, too, of complicated and costly instruments it only requires two pieces of ordinary wire; and it is so easy to make that anyone can put it together in a few minutes.

These advantages cannot be over-estimated in those numerous cases in which prompt surgical interference is necessary to save life, such, for instance, as a bullet imbedded in some dangerous locality. Such a case led to my working out this method. Mr. P. W. Fraser, M.R.C.S. Eng., was shot in the head with a revolver in this city about a year ago. The bullet is still firmly imbedded in his brain in spite of operations carried out at the time of the injury with a view of removing it. Recently I was asked to take some x-ray photographs of it and to localise it. In order to fix the position of the first plane so that it can always be easily found again, it is necessary to have it passing through certain well-known and easily ascertained bony points. In this case I selected for this purpose the occipital protuberance behind and the superciliary ridges in front. A piece of 30-ampère fuse wire was then bent into a ring passing over these bony points, as shown by B D A E in Fig. 2 It will be seen on reference to Fig. 1 that the bullet does not lie in this plane, but it was necessary to work from it, because if the wire ring were removed it was possible easily and quickly to replace it in this position. Theoretically, of course, another plane parallel in all directions to this one but passing through the bullet was made use of, as will be shown later. If the head, with the ring on, is now examined on the fluorescent screen it will be seen that there is one position, and one position only, in which the shadow of the wire on the nearer side of the head coincides in position with the shadow of the wire on the far side of the head, and the ring then appears as a perfectly straight line, as shown by B E A in Fig. 1. This really means that the plane bounded by the wire ring is exactly edgewise to the platinum anode of the x-ray tube, or, in other words, that if this plane were extended in the direction of the tube it would pass through its platinum anode. Care is, of course, taken that the ring is perfectly flat—that is, that when laid on a flat surface the ring will touch it all round. Having now got a well-defined plane or section to use as a base line I proceed to pick out a second plane intersecting the first one but passing through the bullet. This is done by taking another piece of electric fuse wire and bending it to fit over the vault of the head from side to side, thus giving it somewhat the shape of a half hoop. By watching its shadow on the fluorescent screen this second piece of wire can be moved to and fro along the sides of the ring in position on the head until, with the ring showing on the screen as a single straight line, this second piece shows also as a single straight line, C E on Fig. 1, intersecting the bullet. It will be found that to obtain this result the platinum anode of the x-ray tube must be in a straight line with the two points D and E. Care must now be taken to see that the two legs of the half hoop, C E and C D in Fig. 3, where they intersect the wire ring, are equally distant from B, the central point of the back of the head, and consequently also at a distance from A, the central point of the front of the head, equal on each side, though not necessarily the same as the distance from B. If they are not equidistant they must be moved till they are so, showing at the same time as a single straight line intersecting the shadow of the bullet. The electric fuse wire is then carefully soldered to the ring, the redundant ends are cut off, and all distances as well as the angle which it makes with the ring are carefully measured. The measurements shown in the figures were all taken either direct from Mr. Fraser's head or from an x-ray photograph of it. The two measurements marked "diameter"—namely, from A to B and from D to E—are direct measurements taken with calipers. If necessary an x-ray picture may now be taken to show that the position is correct. If it is so the appearance of the picture is shown diagrammatically by Fig. 1.

[1] Scientific American, Feb. 12th, 1898.

[2] The Archives of the Roentgen Ray, vol. v., No. 1.

[3] Walsh: The Roentgen Rays in Medical Work.

This is what has been practically so far effected. Suppose the head to be divided into a number of slices of equal width and parallel to C D in Fig 1, just as a loaf is cut into slices for bread-and butter, I have by the above method picked out the particular slice or section in which the bullet lies. The dotted lines in Fig 1 indicate the divisions between such imaginary slices and the bullet is shown situated in the eighth slice or section counting from the forehead If this particular slice could now be placed flat on a photographic plate and an x ray picture be taken of it the exact position of the bullet in the slice must surely be obtained. As this cannot be done I do the next best thing to it—namely, place the head on a photographic plate in such a position that the slice is parallel in all directions to the plate This is easily done by seeing that the three points D C and E are all equidistant from it. The long diameter of the head is in this position vertical, or nearly so, to the plate. An x ray picture then taken with the platinum anode of the tube situated in a straight line with the two points B and A, so that the ring B D A E throws its shadow as a straight line on the plate shown by D B E in Fig 3, will give an exact picture of the slice or section of the head in which the bullet lies Owing to the fact that the slice is not flat on the plate but is raised some few inches from it, the resulting picture is exaggerated but the exaggeration is practically equal in all parts of it, hence the scale of exaggeration is at once found by measuring with a pair of calipers the true transverse diameter D E on the head itself, and also the apparent diameter between the same points—the two points of junction of the wires—on the photograph The ratio between these two will at once give the scale from which all measurements can be calculated The ratio in the case referred to came out exactly as 5 is to 4 hence one fifth had to be deducted from all measurements on the photograph to get the true measurements On this photograph a line is now drawn through the centre of the bullet and parallel to the straight line D B E in Fig 3 representing the shadow of the ring B D A E The height at which this line cuts the two sides of the wire half hoop over the head, as well as the distance of the bullet from each end of this line are carefully measured and reduced to true measurement by the scale already mentioned It is then plotted on Fig 3 in which it is represented by the dotted line F G This means that with the framework in position on the head the surgeon must measure from the points D and E—the junctions of the two wires—one and a half inches up the vertical wire on each side to obtain two new points F and G a straight line joining which will go through the centre of the bullet at a distance of 1⅝ inches from G and four inches from F The selection of this line F G is really making use of another plane parallel to B D A E but intersecting the bullet as was mentioned at first would have to be done later Thus the position of the bullet is accurately and exactly fixed In order to test the accuracy of the result it is only necessary to use an incandescent electric lamp, say not bigger than a small marble, placed exactly in the position lately occupied by the platinum anode of the x ray tube, and by its means to project the shadow of the wire framework without the head in it on to a

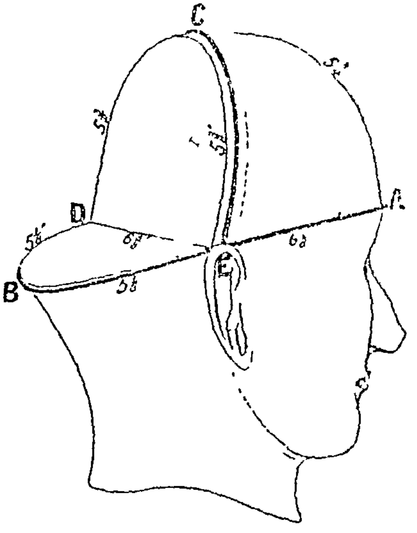
FIG 4



Appearance in all sections posterior to the bullet [illegible] perfectly flat print of the photograph itself. Care must be taken that the framework is placed exactly in the position in which it was when the photograph was taken, and if this is done properly the shadow of the framework cast by the little electric light will be found to be exactly superimposed on its image in the photograph. If now a duplicate bullet or foreign body supported by a wire projecting from a small stand be slowly moved into the framework until it occupies the position obtained from the actual measurements in Fig. 3, the accuracy or otherwise of these measurements is at once demonstrated by the shadow of the bullet as cast by the light exactly coinciding or not with the position of its image in the photograph. In the particular case quoted it was found that the position as given by the measurements was the only possible one in which the bullet would in every way coincide with its image in the photographs.

To apply this method to other parts of the body the wire framework would have to be made in a different way, varying, of course, with the circumstances of each case. To show the appearance of a head if all the sections posterior to the bullet were removed, Fig. 4 was drawn. This could be done on the dead subject with the object of showing, for instance, what portions of the brain the bullet was affecting and what would have to be traversed in order to reach it. Of all the various instruments and methods mentioned at first for localisation by the x rays Professor Waymouth Reid's, at first sight, closely resembles that which I have brought forward in this paper. Very important and essential differences, however, exist between them. Professor Reid only takes one photograph and that apparently without the precaution of having the wire right round the head and seeing that its shadow shows as a straight line. The latter is exceedingly important if strict accuracy is desired. Apparently he endeavours to map out by means of the wire on the cranial surface some well-known brain landmark, such as the Sylvian line, whereas by my method the second wire is moved to and fro along the first wire ring until it picks out the precise transverse section which contains the bullet quite independently of any landmarks at all. Professor Reid gives as an excellent reason for not taking the second cross-photograph the fact that the first was followed by considerable hair-shedding. This fortunately has not occurred in my cases.

In conclusion I must express my obligation to Mr. C. Woodhouse for the great care and skill exercised by him in the production of the diagrams.

Melbourne, Victoria.

SOME REMARKS ON, AND SUGGESTED AMENDMENTS TO, THE HABITUAL INEBRIATES ACTS.

BY L. A. PARRY, M.D., B.S. LOND., F.R.C.S. ENG.

So far three Acts of Parliament have been passed dealing with the question of habitual inebriates, those of 1879, 1888, and 1898. The first of these remained in force for 10 years only, the 1888 Act was simply a renewal of the previous one with some slight and unimportant modifications, and so for all practical purposes they may be considered as one. These Acts deal only with the habitual drunkard who voluntarily seeks cure. They have no reference to the chronic inebriate who does not wish to amend his ways but prefers to continue making himself a plague and expense to his fellow citizens. They simply enjoin that any habitual drunkard who wishes to enter a retreat may, provided he is sober at the time and has complied with certain formalities, be admitted for a specified period, the period to be selected by the applicant. After once signing the applicant has no power to leave till the time has expired provided that it does not exceed 12 months; but under certain conditions he can be discharged by a justice of the peace. If the applicant escapes during his period of voluntary detention he can be recaptured, and if he breaks the rules of the retreat he is liable to a fine of £5 or to suffer seven days' imprisonment.

This is undoubtedly a very good Act as far as it goes, but unfortunately so very small a proportion of heavy and continual drinkers have sufficient strength of mind to submit to the treatment with the hope of obtaining cure of their terrible habits that quite a limited number of individuals take advantage of it. The third Act, which was passed in 1898 and which came into force at the commencement of 1899, differs essentially from the preceding in that it introduces the element of compulsion—the habitual inebriate may under certain circumstances be *compelled* to go to an inebriate reformatory. So far rather less than 18 months have elapsed since the commencement of the working of the Act, but this time has sufficed to reveal a large number of points in which the law is deficient.

Section 1, sub-section 1, deals with the habitual drunkard guilty of crime. It enacts that where a person is convicted on indictment of an offence punishable with imprisonment or penal servitude, if the court is satisfied from the evidence that the offence was committed under the influence of drink or that drunkenness was a contributing cause of the offence, and the offender admits that he is or is found by the jury to be an habitual drunkard, the court may, in addition to, or in substitution for, any other sentence, order that he be detained for a term not exceeding three years in any State inebriate reformatory or in any certified inebriate reformatory the managers of which are willing to receive him. There is no fault to be found with this except that it leaves it to the discretion of the magistrate to decide whether the prisoner shall or shall not be detained in an inebriate home. It would be better that it should be compulsory on the part of the convicting authority to send the habitual drunkard to one of these retreats rather than that it should be left to any particular magistrate who may hold strong views on the temperance question or the reverse. It must be remembered that the Act does not say that a crime committed under the influence of drink is to be punished in this way, but only such a crime committed under the influence of drink by *an habitual inebriate.* This is an important distinction. It would be unfair, perhaps, to give a man a severe extra punishment for committing a crime whilst drunk if the drunkenness were a solitary instance of alcoholic excess, but if the individual is in the habit of getting drunk then let us do our best to prevent him from carrying out further crimes under the influence of drink by endeavouring to eradicate the drinking habit.

Section 2 is the most important of the whole Act. It runs as follows:—

> Any person who commits any of the offences mentioned in the first schedule of this Act, and who within the twelve months preceding the date of the commission of the offence has been convicted summarily at least three times of any offences so mentioned, and who is an habitual drunkard, shall be liable upon conviction, on indictment, or, if he consents to be dealt with summarily, on summary conviction, to be detained for a term not exceeding three years in any certified inebriate reformatory the managers of which are willing to receive him.

The first schedule includes such offences as being found drunk in any public place, being drunk when in possession of loaded firearms, or being drunk on board a passenger steamer and refusing to leave when requested, &c.—in brief, of being drunk under circumstances which are likely to excite the attention of the police. Now the points to which special attention are needed here are many. Firstly, and perhaps most important of all, there is the same point to which reference was made in the discussion of the last section, that is, it is not made incumbent on the magistrate, judge, or other convicting authority to send the drunkard to the inebriates' home. It is left to his choice. Different magistrates take such different views as to the number of times previous convictions for drunkenness are necessary before sending to these homes; some will not do it at all, some wait till 20 or 30 or more convictions have occurred, and others are content with the three times specified in the Act. This renders it necessary that the law should declare that the inebriate should be sent to a reformatory after a certain number of convictions and not leave it to individual opinion. I insert here a few cuttings from newspapers in support of my assertion as to the large number of convictions which are required by some magistrates before they will commit the alcoholic to a home.

From the *Daily Express*:—

> Convicted over 100 times for drunkenness and nine times for attempted suicide, Ellen Macdermott, a flower-seller, was on Saturday sent back to prison for a week for being drunk in the City. And there are homes for inebriates!

From the same paper:—

> Six women who had been convicted 70 or 80 times for drunkenness were each sent yesterday to Bristol Inebriates' Home for two years.

Why should these women be allowed to drink themselves into disease and death and to entail on the taxpayers the expense of repeated police court proceedings? Would it not be more rational at once to put such people into a home and try to reform them and not wait till from 70 to 100 convictions were recorded against them? Even this number does not seem sufficient according to the views of the magistrate who tried the case first quoted above, for he simply sentenced her to one week's imprisonment. It may seem rather a Draconian code, but it is in the best interests both of the individual and the community to put these people under control at the earliest possible moment.

The following sections, 3 to 12, deal with the provision of inebriate homes—a part of the subject which though at first sight may seem of minor importance is in reality of the very greatest moment, for in the practical working of the Act it has been found that one of its greatest drawbacks—a drawback so serious that many experienced magistrates have pronounced the Act useless—is the difficulty of finding homes for the prisoners to be sent to. Over and over again it has been deemed necessary to send a prisoner to one of these retreats, and they have had to be subsequently discharged on account of the inability of the authorities to find a vacancy. This clearly proves that up to the present adequate provision has not been made for such people. As examples let me quote the following. A prisoner was tried under the Inebriates Act at Brighton, and having been found guilty of being an habitual drunkard was ordered to be sent to a home. None could be found and she was therefore discharged. She was drunk again the same evening. The following is from the *Evening News* and refers to a woman charged with being drunk in the streets:—

> A son of the prisoner asked the magistrate to deal with the case under the Inebriates Act. He was the support of the family and in a good position. For a long time past, however, the prisoner's conduct, her drinking habits, and her language had become unbearable. He had been obliged in consequence to send his younger sisters away to a boarding school.
>
> Mr. Fordham: Was she found in the county of Middlesex or the county of London?
>
> The Constable: London.
>
> Mr. Fordham: Then I cannot help you. The Act is a dead letter in London. The London County Council have, it is true, provided a small place for a few people, but that was filled up as soon as it was opened, and there can be no vacancies for a long time yet. All that I can advise you to do is to leave her.

Upon whom, then, is the duty of providing proper accommodation for these cases thrown by the Act? Firstly, the Secretary of State has power to establish State reformatories, and, secondly, county and borough councils and private individuals may, with the consent of the Secretary, establish such homes. As to State reformatories, so far none have been founded, but the Government have at last determined to establish one, which will probably be open shortly. Again, at present very few of the county and borough authorities have availed themselves of their power under the Act to found these homes, and the Act, therefore, is to a large extent a dead letter in consequence. The London County Council has recognised that so far the Act has never had a fair trial, and they are endeavouring to remedy the defects in accommodation for chronic alcoholics convicted under the Act. Mr. Gomme, Clerk of the Council, in a communication to me on this subject, says: "Few applications have been received from the London courts for the reception of males, and the Council has not felt justified in incurring expenditure to erect a reformatory for male inebriates without further evidence of its needs. The subject is not, however, lost sight of, and such measures will be taken as experience of the working of the Inebriates Acts may indicate as desirable." I may mention that Mr. Gomme only refers here to males, not females (who are the worst offenders). I think the lack of application for males, too, is partly due to the fact that it is well-known that there is no accommodation for them and therefore it is useless to apply.

The following extracts from the reports of the Inebriate Acts Committee of the London County Council show to what extent the Council has up to the present proceeded in this matter.

Nov. 2nd, 1900.

[illegible]

1.—By Section 1 [illegible] provided that habitual drunkards [illegible] es punishable with imprisonment [illegible] r the influence of or through drink [illegible] reformatory or a [illegible] State power to [illegible] to make regulations for [illegible] r of inmates from a State [illegible] n special cases from a certified [illegible] cases received at certified reformatories are persons committed under Section 2 of the Act, that is persons convicted of [illegible] therewith who have been within [illegible] the commission of the offence [illegible] times of similar offences and [illegible] objects of certified reformatories and the principles on which they should be managed are set out very clearly in the report of the departmental committee which was appointed to [illegible]

[illegible] s thus laid down, and it is our [illegible] Farmfield in accordance with the [illegible] perience has not yet of course been very extensive, but we have had indications of the desirability [illegible] not to be amenable [illegible] departmental com- [illegible] erect has decided [illegible] at Duxhurst next [illegible] "I find satisfactory [illegible] nt of classification [illegible] formatories ...... Dangerous cases are [illegible] be answerable." In a circular dated [illegible] State, after stating that he had given [illegible] stion of exercising his power of estab[illegible] id: "The department has been con[illegible] culty that it has been unable to form any estimate which I can regard as even approximately trustworthy of the number of persons for whom provision should be made in a State reformatory." It will be remembered that the Council was confronted with the same difficulty as regards a certified reformatory, but has, [illegible] already [illegible] State [illegible] much [illegible] mental [illegible] ified reformatories [illegible] of accommodation required may not yet be available, but the principle to be acted upon would appear to be that adopted by the Council of providing a certain amount of accommodation to meet present requirements and making provision with a view to necessary extension in the future. We accordingly recommend "That a letter be addressed to the Secretary of State urging the desirability of a State reformatory being established for the reception of persons committed under the Inebriates Act, 1898, who cannot be suitably dealt with in certified reformatories." (Adopted.)

5th December, 1900.

Royal Victoria Homes, Brent[illegible].—Negotiations.

[illegible] the information of the Council, the [illegible]

[illegible] it was ready. It is [illegible] Secretary of State for orders of transfer, but the managers subsequently intimated to the Home Office that they would only require one vacancy [illegible] kept at Farmfield, as all the London patients except one [illegible] licences. No order has been received for the transfer of any of the patients to Farmfield except a woman who was charged when out on licence from Brentry and sent to Farmfield from the Clerkenwell Police-court. The offer of 1s. per day as from 12th June [illegible] has not been accepted but a claim of £[illegible] 9d. has been made for [illegible] out of pocket expenses in respect of London patients. The liability for this has, under the solicitor's advice, been repudiated. A subsequent [illegible] offer has been received from the managers of the homes to receive London patients under a five years' agreement, on payment of £20 per annum for each bed reserved under the agreement, whether occupied or not. Having regard to arrangements we contemplate for the provision of additional accommodation at Farmfield we have not felt justified in recommending the acceptance of these terms or the arrangement of an agreement for so long a period. In a letter since received it is stated that the terms offered by the managers are the only ones they are authorised by their board to adopt, but an offer is made to lay before the Board any suggestions we may have to make in the matter. In view of the manner in which previous suggestions have been received and the improbability of any mutually satisfactory arrangement being arrived at, we have not felt that any object would be served by availing ourselves of this offer.

Female Inebriates—Additional Accommodation—Capital Vote (original outlay) £20,000.

2.—We have to report that the accommodation for which the Farmfield Reformatory is certified is now occupied and that no more women can at present be received at the reformatory. The Council is aware that there are 17 London cases at Duxhurst and 43 at Ashford under agreements between the Council and the managers of these homes, so that provision has now been made for 90 cases by the Council, and beyond 13 places for Roman Catholic women at Ashford there is no further accommodation immediately available. We have had several applications from the London courts for the admission of female inebriates since Farmfield was full, and the following return, which has been forwarded to the Home Office by the chief magistrate, indicates the need of the early provision of further accommodation.

Return of the number of persons repeatedly convicted of offences of drunkenness at the metropolitan police-courts during the year ended Oct. 31st, 1900:—

Court.	Number of persons convicted.							
	3 times.		4 to 5 times.		6 to 10 times.		Above 10 times.	
	M.	F.	M.	F.	M.	F.	M.	F.

Clerkenwell	3	10	4	10	1	3	—	—
Marlborough-street	7	22	2	14	6	11	—	1
West London	16	25	8	17	4	9	1	—
Marylebone	21	50	8	20	—	9	—	1
Westminster... ...	7	9	1	—	2	—	—	—
South-Western ...	5	16	7	11	—	14	—	—
Lambeth	8	18	5	22	1	14	—	2
Southwark	18	40	11	36	4	20	—	4
Greenwich	8	12	6	14	—	1	—	—
Woolwich	11	18	9	24	2	10	—	—
Thames	28	16	28	6	11	—	1	—
Worship street ...	1	7	3	18	2	4	1	1
North London ...	12	2	13	1	3	—	—	—
Totals	161	258	119	223	41	107	4	9

In view of these figures and our own experience we have felt it our duty to take immediate measures for the provision of additional accommodation at Farmfield where, the Council will remember, there is ample room for expansion. We have had before us alternative plans and estimates prepared by the architect providing for the accommodation of 80 more women. Regard has been had in the preparation of the plans to the possible need of a further extension of the buildings in future. The plan which we have selected as the most suitable is for a central administration [illegible] compounds, each containing cottage [illegible] 20 patients, thus affording a possibility [illegible], if the work under the Act is to prove a success, our experience has already shown to be an absolute necessity. In order that measures may be at once taken for getting the work put in hand so as to have the urgently needed accommodation available as quickly as possible it is hoped that the Council may feel justified in suspending the Standing Order as to capital expenditure amounting to over £5000 to avoid the decision on our recommendation standing over until after the Christmas recess. We recommend: (*a*) That Standing Order No. 34 with regard to recommendations or proposals involving expenditure upon capital account of sums exceeding £5000 be suspended to enable the Council to vote without an interval of seven days upon the following recommendations. (*b*) That the estimate of £20,000 submitted by the Finance Committee be approved and that an expenditure of that sum be sanctioned for the construction and furnishing of additional buildings for the accommodation of 80 female inebriates on the Farmfield estate and for incidental works and expenses in connexion therewith. (*c*) That the Inebriates Acts Committee be authorised to invite tenders and take other necessary measures for the execution of the works. (Adopted.)

But, excellent as the action of the London County Council is, this is not sufficient. What is required is that all county councils should do the same, and as they will not do it voluntarily the Act should be so amended that county and borough councils should be compelled to provide adequate accommodation for their inebriates. Small districts could combine or could by arrangement contribute towards an establishment maintained by a large council. In this way there would be no discharge of prisoners on account of inability to find proper accommodation.

The great omission from all these Acts is this, there is no provision whatever made for chronic drunkards who never put themselves into the hands of the police, who always indulge in their own homes, and who keep there when they are drunk. They wreck and ruin their own lives and those of all connected with them, they destroy the happiness of many and many a home, and yet there is no law by which they can be touched. I believe the sooner they are treated in the same manner as lunatics the better it will be for everybody. Let it be, just as it is in the case of the insane, in the power of the nearest of kin or some other responsible person to get the chronic alcoholic committed by a justice of the peace, after two independent medical men have certified as to the fact of the chronic inebriety, to a home for drunkards till he or she (unfortunately, only too often the latter) is cured. These people are worse than lunatics—they do more harm both to themselves and others than do insane people, and yet we are so tender of the "liberty of the subject" (here only the liberty to drink themselves into misery and death) that we will not treat them in a way which is for their own and everybody else's good. Until some such clause as this is inserted no Act of Parliament will be complete. So far we have no power whatever to deal with the chronic drunkard who manages to indulge in his vice in private; the law must eventually give the power—the sooner the better.

Hove, Sussex.

APPENDICITIS: SOME GENERAL REMARKS ON THE PATHOLOGY AND TREATMENT.

BY FREDERICK GEORGE LLOYD, M.R.C.S. ENG., L.R.C.P. LOND.,
CIVIL SURGEON, GUARDS' HOSPITAL, BRIGADE OF GUARDS, LONDON.

THE following essential facts in reference to appendicitis are no doubt quite familiar to my fellow practitioners, but I record them because in my practice they have recently served to confirm accepted teaching. I have verified as far as possible the observations which I have made by research at the Royal College of Surgeons of England, the Royal College of Physicians of London, St. Bartholomew's Hospital, and the Guards' Hospital, London.

Appendicitis means inflammation of the vermiform appendix. It is to be distinguished from a similar condition of the cæcum known as "cæcitis" and of the ileum known as "ileitis." Appendicitis may be divided into the following varieties which differ from one another rather in degree than in kind and correspond with the varieties of inflammation to be met with in other parts of the body: (1) acute appendicitis—(*a*) with local inflammation of the peritoneum or the cellular tissue, (*b*) ending in suppuration and abscess, (*c*) ending in gangrene, and (*d*) ending in perforation; (2) chronic appendicitis; (3) relapsing appendicitis; and (4) latent appendicitis.

PATHOLOGY.

Disease of the appendix vermiformis is very common and morbid changes are met with in about 20 per cent. of all bodies examined post mortem. On post-mortem examination it may be found in one of the following conditions of inflammation: (1) confined to the surface of the lumen; (2) involving one or more of its coats; or (3) "perforating" its peritoneal coat or dissecting between the layers of its mesentery. The inflammation present may be of the simple, specific, or malignant variety.

Conditions of the appendix.—1. Appendicitis with abscess may be found to have tracked in one of the following directions: (1) into the cæcum; (2) into the cellular tissue; (3) into the abdominal wall; (4) into the rectum; (5) into the uterus or its appendages; (6) into the bladder; (7) into the peritoneal cavity either direct or after being extraperitoneal; (8) involving the sheath of the psoas muscle or opening up the iliac vessels (rare); (9) through the sciatic or obturator foraminæ or through one of the abdominal "rings"; or (10) in the extra-peritoneal variety it may burrow up behind the colon and perforate the diaphragm, giving rise to pleurisy, pneumonia, or pericarditis. In appendicitis with perforation into the peritoneal cavity there is a tendency for the pus to travel in the most dependent positions (i.e., into the recto-vesical pouch); both the true and also ligaments of the bladder are frequently involved in this variety of inflammation. 2. The appendix may be (*a*) twisted upon itself or kinked, giving rise to mucocele, empyema, gangrene, or perforation; (*b*) it may be the seat of one or more stricture, or may be obliterated from old inflammation or ulceration; or (*c*) it may constitute an intussusception or hernia (the appendix may be found completely invaginated or forming a partial or complete hernia of one of the following varieties—inguinal, femoral, obturator, umbilical, or ventral); (*d*) it may be considerably elongated and lying in one of the following positions—over the pelvic brim or adherent to the abdominal wall or to any structure mentioned as in relation with it; or (*e*) it may be the seat of embolus or thrombosis, or of tubercle, carcinoma (primary or secondary), or secondary deposits of actinomycosis or, again, of parasites or worms. The tendency of any one of these conditions of inflammation is to obliterate the process.

In suppurative appendicitis with perforation and acute diffuse septic peritonitis pus very rarely extends higher than the transverse mesocolon.

Appendicitis may terminate in resolution, complex adhesions, suppuration (intra- or extra-peritoneal), or gangrene with or without perforation. The terminations of the suppurative or gangrenous varieties after operation may be (1) in resolution; (2) recovery with adhesions; (3) fistula; or (4) death from pyæmia, lardaceous disease, or exhaustion.

Bacteriology.—The bacillus coli communis is constant, but except in diseased or damaged tissues or tissues whose vitality is lowered is inactive. In disease the following additional varieties have been demonstrated: cocci, micrococci, diplococci, pneumococci, bacilli, tubercle bacilli, leptothrix, saccharomyces, and some others.[1]

Causes.—The causes of appendicitis may be simple, specific, or malignant. The exciting causes are numerous. Some of the commonest may be classified as indigestion arising from any of the usual causes; cold; injury; foreign bodies; concretions; constipation due to pressure and chemical irritation lowering the vitality of the wall of the tube and thus being the seat of action of the bacillus; diarrhœa, dysenteric, typhoidal, and tuberculous causes; [illegible] ary and secondary). [illegible] The symptoms may be divided [illegible] There are three cardinal symptoms—(1) pain, (2) tenderness, and (3) rigidity; and two others are usually present—viz., fever and constipation. The intensity of the symptoms varies somewhat with the degree and variety of the inflammation as in other parts as well as to the structures implicated.

In diagnosis the questions which present themselves are three in number: (1) Is this a case of appendicitis? (2) What is the probable condition of the appendix? and (3) What variety of appendicitis is it? With regard to the first of these questions the following diseases may have to be excluded by differential diagnosis, each condition mentioned having a specific history and cardinal symptoms of its own: (*a*) colic—intestinal, renal, hepatic, pancreatic, and splenic; (*b*) obstruction—acute (strangulated intestine), pseudo-strangulation, perforation of the gastro-intestinal tract other than appendicitis, hæmatocele, parasites and worms; (*c*) if fever is present typhoid fever and pneumonia before consolidation; and (*d*) intussusception in children. In the chronic and relapsing varieties of appendicitis the following diseases more or less simulate appendicitis: tuberculosis of the cæcum, cancer of the cæcum, psoas abscess, perinephritic abscess, disease of the uterus, ovaries, or Fallopian tubes, and hip-joint disease. The following considerations may help us in our diagnosis: the seat of pain; the occupation of the patient; the history of the present illness, past illnesses and environment; the present condition as evidenced by pain, tenderness, rigidity, the cachexia of the patient, facial expression, pulse, tongue, temperature, respiration, the urine, the stool, the vomit, and the expectoration; auscultation of the abdomen and chest; the use of the exploring needle; and laparotomy.

In connexion with the second question the same considerations which helped us to answer the first question are applicable to this one.

Respecting the third question, What is the variety of appendicitis? we must as with the second question be guided by the same considerations together with the acuteness of the symptoms, the duration of the disease, and the local signs present. If peritonitis be present in addition to fever and vomiting there is usually painful micturition or retention of urine, rigors, and one or both legs are drawn up. The abdomen is tympanitic in front owing to the presence of free gas and is partially dull in the flanks. The right lower quadrant of the abdomen, in addition to being exquisitely tender and fixed, is sometimes resonant, sometimes dull, depending upon the presence or absence of free gas and the condition of the parts between the finger and the appendix. Even in ultra-acute appendicitis the temperature frequently does not rise above 103° F. or the pulse exceed 120, but there are present all the usual signs of collapse accompanied by rigors and vomiting. The vomit is usually greenish in colour but in the latest stages if the patient is not operated upon it becomes more or less fæcal in character.

Course and prognosis.—The tendency of appendicitis is to recovery. Appendicitis may be so slight as merely to give rise to a feeling of slight discomfort without even laying the patient up. On the other hand, it may give rise to all the signs and symptoms of acute septic peritonitis. Any intermediate stage may be met with. In appendicitis 11 per cent. of the cases are fatal. With abscess it is about 30 per cent., but when surgically treated it is put as low as 2 per cent. Some of the most acute cases end fatally in from 36 to 48 hours, more commonly about the end of the first week. In 50 per cent. of fatal cases death takes place within eight days. An ordinary attack of appendicitis lasts from seven days to three weeks. The extra-peritoneal variety of abscess, if surgically treated, offers a most favourable prognosis. In the intra-peritoneal variety prompt action is needed and except in the early stages radical measures, which will be described under "treatment," are imperative. In about 8 per cent. of the cases the pus enters the peritoneal cavity by dissecting between the layers of its meso-appendix.

TREATMENT

The general rules in the treatment of inflammation of the vermiform appendix are the same as in the treatment of inflammation in other parts. When appendicitis is suspected or diagnosed the patient should be placed at rest in the recumbent position. The diet should be restricted, nutritious, and spare, very little being given by the mouth. The application of warm fomentations and leeches in the right iliac fossa or at the seat of the pain is sometimes of benefit, especially in the earlier stages of acute case. A mild saline aperient should be employed in the early stages so as to clear out the intestine and should be followed by a simple enema. If there is much distension there should be added a little turpentine to the enema and the rectal tube should be passed from time to time. When the diagnosis of variety has been made out, and not before, a little opium may be given either as an injection of morphia (one-sixth of a grain) or in the form of the liquor opii sedativus 10 minims twice in the day, according to the amount of distress. If the symptoms are acute no food should be given by the mouth except a few spoonfuls of milk and a little ice to suck to relieve thirst, the patient being fed by rectal enemas. The treatment should correspond to that for acute peritonitis combined with a little antiseptic, say, salol 10 grains three times in the 24 hours. Cases of acute, chronic, and relapsing or latent appendicitis are best treated in this way unless ultra-acute symptoms have presented themselves.

Operative measures.—The great majority of cases call for *no operative treatment*. In ultra-acute cases operation should be performed early. Operations for appendicitis do [illegible] in the not differ [illegible] extra abdomen [illegible] In peritoneal the extra-peritoneal variety the incision should be made as low as possible so as to avoid opening the general peritoneum—i.e., half an inch above Poupart's ligament along the outer half according to the point of maximum dulness and resistance with the patient under an anæsthetic. During the incision the muscular fibres should be separated according to McBurney's method. Appendicitis with intra-peritoneal mischief and septic peritonitis requires very careful packing and sponging so as to try to prevent septic extravasation.

In early acute septic inflammation without suppuration an incision should be made and the appendix removed and then should be a thorough sponging away of all septic material. If there has been some days delay or the peritonitis is very acute from the first an incision is made over the seat of the appendix and it is removed. An incision is then made at a point midway between the ensiform cartilage and the umbilicus and carried as far as the pubes. The intestines are turned out and cleaned, being kept by an assistant at the body temperature by the application of hot sterilised towels. With the intestines thus turned out the peritoneum can be thoroughly flushed and sponged free from all pus and extravasated fluid, special attention being paid to the recto-vesical pouch and other cul-de-sacs of the abdominal cavity. When every visible particle of septic material has been removed we have next to deal with the intestines. When they have been flushed and sponged incisions should be made into the distended coils in sufficient number to empty them of gas and liquid fæces and the peritoneum should be united by Lembert's method. The intestines are then returned into the abdomen and a drainage-tube is inserted at the lower part and the abdominal wall is sewn up with silk-worm gut. Shock should be counteracted by the usual methods as far as possible—i.e., the limbs should be wrapped in cotton-wool and the operation should be performed on a hot-water bed or table. Time must not be wasted during the operation. Subcutaneous injection of strychnine and brandy injections per rectum should be administered. The decision of the surgeon as to prolonging an operation in a given case must depend on the condition of the patient and cannot be decided by rule. Amputation of the appendix in these cases is sometimes easy and sometimes difficult or impossible on account of extensive adhesions. The operation should be done with strict antiseptic precautions. When a second incision has to be made the first should be closed temporarily with gauze and collodion flexile after sewing up.

---

[1] Javel and Laur, Leipzig, 1893; Lockwood, 1901.

Amputation of the appendix.—The appendix should be clamped three-quarters of an inch from its base. The first incision should be made through the serous and part of the muscular coat: this is turned back, and the remainder is cut through; the stump is then touched with a wooden match dipped in carbolic acid, the flap turned over it, and it is sewn up, first of all the mucous coats and then the serous coats, by Lembert's suture. A little graft of omentum may be placed over this. If the appendix is sloughing or gangrenous it should be tied with catgut and snipped off with the scissors. An indiarubber tube of large size is then passed to the bottom of the cavity in suppurative cases; in non-suppurating cases the wound is closed. The cavity in suppurating cases is best drained by suction—i.e, passing a smaller tube attached to a syringe to the bottom of the larger one and thus drawing off the contents and repeating the proceeding at each dressing. All tubes, syringes, &c., should be kept in carbolic solution, 1 in 20. The after-treatment is similar to the after-treatment of other abdominal operations except that in the gangrenous and perforative varieties of appendicitis with peritonitis the cavity is very difficult to drain and irrigation must be limited to cleansing the tube and the superficial parts. The sinuses remaining in these cases exhibit a tendency to close spontaneously in time, but are usually very slow and difficult to heal. The appendix should be removed during a quiescent period for preference, but when an abscess is present the surgeon should operate at once. There is no fixed day for operating, but too early and too late operation are to be strongly condemned. In the relapsing variety of appendicitis the operation should be performed after the second attack in the quiescent period unless ultra acute symptoms supervene, in which case operative measures should be taken at once.

CONCLUSIONS.

1. Although in America the exploring syringe has been used with considerable success as an aid to diagnosis, still, on account of the septic condition of the parts and the depth of tissue as well as the possibility of missing the pus, a laparotomy would appear preferable and is usually practised in this country. The exploring syringe is no doubt of use in a few cases.

2. In addition to making a counter opening in the loin or in the female behind the cervix uteri I am of opinion that aspiration or a small counter opening per perineum or per rectum when the pus is collected in these localities may prove of practical value and in some cases the passage of a drainage-tube or gauze wick.

3. It is well to remember in making incisions when peritonitis is present (1) that the peritoneum is of a dull red colour, and it is often as much as half an inch in thickness; (2) that adhesions must be divided and not torn through; (3) that the visceral and parietal layers of peritoneum are usually adherent; (4) that the small intestines are often glued together and if opened by accident they should be united by Lembert's sutures; (5) that the bladder is sometimes dilated and adherent; (6) that each bit of omentum should be transfixed and tied at both ends; (7) that if the whole appendix cannot be moved tie and dissect away part of it; (8) that the amount of pus present in the peritoneal cavity in perforation cases varies from a few drachms or ounces in the direct perforating variety to as much as a couple of pints when the abscess has been first of all extra-peritoneal and afterwards burst into that cavity; (9) that 70 per cent. of cases of appendicitis get well on careful medicinal treatment alone, and that although a new set of false teeth, attention to the bowels and to diet have warded off relapse, gangrenous appendicitis occurs in upwards of 15 per cent. of cases; and (10) that all cases of appendicitis may develop into the ultra-acute variety requiring surgical treatment, but that the tendency of appendicitis is to recovery.

THREE POINTS IN PRACTICAL MIDWIFERY.

BY G. W. ORD, M.R.C.S. ENG., L.R.C.P. LOND.

SOME 12 years ago I arrived home from a confinement in a state of exaltation: I had saved a life, not the mother's, but the child's, and, as I thought, in an entirely new and original manner. The presentation was a breech, and for certain reasons it was highly important that a living son should be born. In due course the body was born; there was the much-desired son, three-quarters of him, and with a pulsating cord. Then followed the usual hitch; the head absolutely refused to leave the mother, the cord ceased pulsating, and it seemed that the child would be born asphyxiated. I had a catheter in my bag, as it chanced a silver male instrument, and feeling my way I passed it into the child's mouth. The child cried down the catheter, the chest became inflated, and my anxiety ceased, for I saw no reason why the child, if needs be, could not remain in that position with the catheter in his month for several hours. A minute later I passed another catheter—this time a female instrument—to double the air-supply, and the thought of an old picture with a shepherd playing the tibiæ crossed my mind. "Age, tibicen, refer ad labias tibias, suffla celeriter tibi buccas." In the end, six or seven minutes later, the head was born and all was satisfactory, though I remember the father for weeks afterwards making a fuss about a little hard lump in the child's arm at the site of an injection of ether. On my arrival home I searched to see if my method had been anticipated, and in Playfair's work on midwifery I found it, but inasmuch as the method has been a surprise to every medical man to whom I have told the tale I consider my case, if generally known, may be a means of saving infant life, the mortality in breech presentations varying from one in 11 to one in three and one-fifth. Playfair, indeed, says of the catheter method that it is "not reliable." In my case the catheter did its work perfectly, and I cannot conceive a single argument against it; moreover, Playfair gives none. With the whole body born it would appear easy to drag, by manipulation, the head into the world, so that the catheter seems unnecessary. In practice, however, a delay of three or four minutes frequently occurs, enough, apparently, to account for the high mortality.

I wish to touch upon another matter in which I have had experience. Hour-glass contraction of the uterus, I am positive, is not caused by traction on the cord, as Playfair believes, but by traction on the infant, who is thereby too rapidly removed from the uterus. This is, I believe, a new assertion and I must therefore justify it. In the earlier years of my practice, though I never used traction on the cord and always waited for from 15 to 20 minutes by the watch before attempting "expression," yet I had numerous cases of hour-glass contraction. In none of the cases had ergot been given. Especially did I find contraction occur after instrumental delivery. For the last six or eight years I have pursued the method of "expressing" the child after the birth of the head and have had no hour-glass cases when

I have been present before the birth of the child. I cite two cases. I attended two women each in three confinements and each woman had hour-glass contraction with the first two children. At the third confinement in each case, pursuing a policy of *vis a tergo* only on the child, I found, as I expected, the placenta easily expressible after a wait of a quarter of an hour. I have, however, never considered hour-glass contraction a "bugbear." It is only a delay and a nuisance. The hæmorrhage in my cases has been trifling and the non-separated, not the adherent, placenta is easily peeled off when once the hand gets through the constriction. As a delay and a nuisance, however, it is well avoided, and if by a warning against traction on the child one can do so my object in writing will be achieved.

It appeared to me in the hour-glass cases (1) that the contraction took place when the infant had been rather quickly delivered and when the placenta was situated in the fundal region of the uterus, therefore that there are two factors required for its occurrence; (2) that the fundal portion of the uterus was tightly contracted around the placenta whilst the lower portion of the uterus was lax and flabby (Dr. Herman, however, says that "the contraction of the circular fibres of the lower uterine segment ...... morbidly persists."); (3) that the amount of hæmorrhage was only normal, as might be expected from the tonic contraction of that portion of the uterus containing the sinuses; and (4) that the constriction, which to commence with would only admit one finger besides the funis, was, generally speaking, situated quite half way or higher in the uterine cavity.

Again, I am not at all certain that traction on the infant is not responsible for many cases of pronounced scoliosis at a later age. I do not mean mere amenability of the spinal column, for that, if looked for, will be found to be an unexpectedly frequent occurrence. I think investigation would probably show that an inordinate number of the badly twisted spines had been breech or transverse presentations at birth. Certainly this is so in the few cases about which I have made inquiries. Thus out of eight cases three were breech, two were probably and two were possibly breech presentations, and one was vertex (this last suffers from marked rachitis). To deliver breech presentations traction on the child is nearly always made use of. Now in the mechanism of breech delivery it is said that the shoulders *do not follow the movements of the hips and that consequently the spine is rotated.* Rotation and traction will necessarily stretch the vertebral ligaments and we ought not *to be surprised that when the child becomes a certain weight*—i.e., at from seven to 12 years of age—twisting should occur along the line of least resistance—that is, along the line of overstretched or torn intervertebral ligaments, *for a torn or overstrained ligament never entirely recovers its pristine strength.*

To conclude, in this paper I have touched on three topics and I hope I have made three points: (1) that the catheter in the course of a breech delivery is capable of saving life; (2) that hour-glass contraction of the uterus is avoidable; and (3) that scoliosis is possibly caused by traction on the infant's body during birth and that we should realise the damage we may be doing to the spine when pulling in the various directions as we are advised in text-books and be wary accordingly. Besides the possible scoliosis, the foundation of which we may be laying by traction on the infant's body, there is another and a more serious danger which we may be unwittingly incurring during that operation—the suprarenal capsules may be injured and death of the child follow. I quote from Dr. Clifford Allbutt[1]: "As the result of traumatism during birth hæmorrhages frequently occur into the suprarenal capsules. On an examination of 130 stillborn children Dr. H. Spencer found extravasations into these organs in 26. These hæmorrhages occurred more often in difficult labours and were more frequently met with in pelvic than in cephalic presentations." Speaking generally, I believe in the soundness of the use of the catheter with an after-coming head if any hitch occurs as opposed to traction on the infant's body.

LONDON FEVER HOSPITAL.

A CASE OF EXTENSIVE HÆMORRHAGE INTO THE FLOOR OF *THE MOUTH AND EPISTAXIS OCCURRING IN A HÆMOPHILIAC* DURING THE COURSE OF SCARLET FEVER; RECOVERY.

(Under the care of Dr. CHARLES R. BOX.)

IT is curious that medical literature contains hardly any records of the behaviour of hæmophiliacs in the course of the specific fevers, but this very fact demonstrates that as a rule their tendency to bleeding does not specially manifest itself on these occasions. The following case is remarkable and is very deserving of record.

A youth, aged 16 years, was admitted into the London Fever Hospital certified as suffering from scarlet fever. He was apparently in good health until two days before admission, when he shivered and vomited. When admitted the

being only a faint

remains of a similar

and flexures of the

elbows. The tonsils were reddened and moderately swollen; the submaxillary glands were slightly enlarged. The posterior cervical glands were not involved. The tongue was coated white and cleaning on its anterior part. The urine on admission contained no albumin. There was no evidence of any visceral disease. The temperature was 102·4° F. After being in hospital three days the temperature fell to normal and the patient felt quite well. On the eighth day of the disease the temperature began to rise and next day a trace of albumin appeared in the urine. Two days later the temperature reached 102·2° and rheumatism with lumbar pains was present. The tonsils were swollen, the left submaxillary glands were again enlarged and tender, and the albumin was increasing in quantity. On the inner side of the left arm just above the elbow a discoloured area of about the size of a florin appeared, evidently a subcutaneous hæmorrhage. There were no other hæmorrhages and the patient was inclined to think that he had bruised his arm on the side of the bedstead. The next night sleep was much disturbed and at four in the morning there were pain in the left side of the jaw and some difficulty in swallowing. The submaxillary region was much swollen, tense, and tender. The floor of the mouth was infiltrated with blood extravasated into its tissues and the tongue was pressed upwards towards the roof. A few hours later profuse epistaxis occurred and was once repeated. The local application of hazeline and calcium chloride in solution appeared to stop this. The temperature remained febrile. Further careful inquiry was now made as to the previous history of the patient and his family. As a boy he had lost a considerable quantity of blood after a tooth extraction. His mother's uncles and mother's sisters' sons were "bleeders" and other more remote male relatives suffered from the same tendency. Most had lived to a good age.

The hæmorrhage into the floor of the mouth continued to increase and the patient presented exactly the appearance of one suffering from Ludwig's angina. Feeding was a matter of the greatest difficulty. The external swelling extended far down towards the sternum and increasing stridor caused the greatest apprehension, for the difficulties and dangers attendant upon tracheotomy would have been most formidable. Fortunately, however, at this stage improvement commenced and under the influence of an ice-collar and full doses of calcium chloride the extravasation ceased to extend. Ulceration of the mucous membrane of the mouth now threatened and there appeared to be considerable danger of the extravasated blood becoming infected in this way. Absorption, however, proceeded apace and the mucous membrane assumed a healthier appearance. Six days after its onset the extravasation had entirely disappeared. An area of pleural friction now developed in the right axillary region and was accompanied by considerable pain. The friction was not accompanied by signs of effusion of fluid or of lung consolidation, and cleared up almost as quickly as it commenced. It was possibly due to local hæmorrhage. A few punctiform hæmorrhages also appeared on the soft palate. On the twenty-sixth day of the disease there was a sharp attack of cervical adenitis, with fever, and some increase in the quantity of albumin in the urine, a trace of albumin having been almost constantly present from the beginning. The adenitis subsided quickly and the albuminuria gradually diminished. The patient was discharged on the fiftieth day.

Remarks by Dr. BOX.—This case is of such exceptional character as to deserve to be recorded. True hæmophilic manifestations are rarely met with during the course of the specific fevers; in fact, in my experience the case is unique and I have not been able to find a record of anything similar. A case like the foregoing naturally raises the question of the dependence of the hæmorrhagic form of the specific fevers upon a hæmophilic tendency in the individuals attacked. There appears to be no evidence which would enable one to assert that this is so. So remarkable a coincidence could not fail to have attracted attention long before now, and cases would be sure to have been recorded. On the other hand, I have heard of several instances where the children of "bleeder" families have recovered from attacks of the specific fevers without any hæmorrhagic manifestations and such cases must be of frequent occurrence. The distribution of the hæmorrhages in the floor of the mouth and in the arm in this case was such as to suggest that some slight injury was concerned in their production rather than that they were dependent upon the scarlatinal infection. The bleeding in the floor of the mouth might well have been induced by the use of the throat spatula and that near the elbow by a blow, as suggested by the patient. The epistaxis is not so easy to account for in similar fashion. The rapidity with which the effusion subsided under the influence of the ice collar and full doses of calcium chloride was remarkable. I am much indebted to Dr. C. Todd, who at the time was acting as assistant medical officer, for his careful observations and investigations of the case.

CHATHAM NAVAL HOSPITAL.

A CASE OF HEPATIC ABSCESS; OPERATION; RECOVERY.

(Under the care of Surgeon R. F. BATE, R.N.)

OUR knowledge of the etiology of abscess of the liver is still incomplete. Many of these abscesses, probably a majority, are produced by septic emboli carried from an ulcerated surface in the stomach or intestines by the portal vein to the liver. There are others, however, which are in all probability produced by micro-organisms which have obtained access to the liver by the channel of the bile-ducts. Other abscesses are produced by suppuration occurring in hydatid cysts. With our present knowledge we are unable always to distinguish between these various forms, and bacteriology can afford us valuable assistance in discriminating between them. It is therefore always highly desirable that a bacteriological examination should be made of the pus evacuated from an hepatic abscess. The following case shows how very satisfactory is the modern treatment of this serious condition. The case is published by permission of the Director-General of the Medical Department of the Navy.

A man, aged 24 years, was admitted into the Chatham Naval Hospital on June 7th, 1901, from H.M.S. *Wildfire*. The patient had been on the sick list since May 28th, suffering from acute pains in the left hypochondriac region, cough, and debility with febrile symptoms. A swelling gradually formed in the epigastric region. He had had no liver trouble previously; he was 20 months on the East Indian station, being invalided for beri-beri in November last. On examination there was a tense swelling occupying the epigastric region and reaching to within one and a half inches of the umbilicus, which was dull on percussion, with fluctuation present, and was apparently connected with the left lobe of the liver. There was enlargement of the spleen, the tongue was thickly coated, and the evening temperature was 100·8° F.

An exploratory puncture was made over the swelling and a drop of light yellow fluid was withdrawn which on examination showed pus cells. The abdominal wall was prepared for operation, and on June 11th at 11 A.M. the patient was given the A.C.E. mixture. A slightly oblique abdominal incision for three and a half inches was made over the most prominent point of the tumour, and the tissues were carefully divided down to the peritoneum, which was fortunately found to be adherent to the abscess. This was then opened freely, care being taken to prevent matter from entering the abdomen by packing around with large flat sponges. 16 ounces of sweet-smelling pus were withdrawn. Only a couple of small vessels in the abdominal wall had to be ligatured and there was but moderate venous oozing from the liver substance. Six deep fishing gut sutures were introduced by a curved needle through the margins of the abscess wall and the peritoneum, and were carried deeply through the tissues of the abdominal incision. A large drainage-tube was then introduced and the abscess cavity was washed out with saline solution; a couple of gauze plugs were also inserted. The abdominal wound was closed by six catgut sutures and a few horse-hair stitches and a dressing of iodoform and sal alembroth wool applied.

At 5 P.M. the wound was re-dressed, serous oozing being present on the dressings. The patient had vomited bile-stained fluid. The evening temperature was 98·2° On June 12th the temperature was 98° and the pulse was 76 and of good volume. The tongue was slightly coated. Bilious vomiting continued off and on to 1 A.M. The wound was re-dressed; the plugs of gauze were removed; there was slight blood-stained watery discharge, not offensive. The tube was syringed out with warm boric lotion. On the 13th there was a less amount of watery blood-stained discharge on the dressings. The tube was shortened half an inch. The bilious vomiting ceased. The tube was removed on the 15th and gauze plugs alone were used. On the 17th the upper sutures were removed. The temperature and the pulse were normal. From the 17th to the 23rd the patient did well, being ordered on the latter date boiled fish diet. The wound was granulating satisfactorily. On the 30th the wound had healed and he was discharged to duty.

Reviews and Notices of Books.

The Theory and Practice of Military Hygiene. By EDWARD L. MUNSON, A.M., M.D., Captain, Medical Department, United States Army. Illustrated by Eight Plates and nearly 400 Engravings. London: Baillière, Tindall, and Cox. 1901. Pp. 980. Price 32*s.*

THIS is in many respects a remarkable book. It contains such an amount and variety of information that its production represents an enormous expenditure of time and labour as may be well imagined when its author tells us that although no bibliographical index is given some 2700 authorities have been referred to and consulted. The author has not simply depended upon his experiences in the United States army, but he has drawn his material from the history of all armies.

When Parkes, as professor of military hygiene at the Army Medical School, first brought out his work on Practical Hygiene the subject was new, the reduction of the laws of health and hygiene to a scientific basis, and their systematic application to armies in the field, in warfare, in camp, and in garrison, had not been attempted, and his book was consequently at that time an epoch-making one. It conferred an immense benefit on the army and has given rise to a number of lineal descendants in the series of new editions that followed. At the present moment the subject of military hygiene is a vast one which is bound to go on growing in importance. But it will grow also in difficulty of practical application, owing to the diverse channels of infection and the complex nature of the problems which bacteriological investigations have opened out, although these have tended to lend more precision to our aims and scientific methods of unravelling and tracing out disease causes. The author of the volume under review tells us that the more complete works on general hygiene contain much material which has no applicability to the military service and that on the other hand they leave unnoticed a large number of subjects a knowledge of which is of the highest importance to the military sanitarian. This is so. His aim has been to furnish a text book dealing directly with the sanitary problems peculiar to the military service which shall be available not only as a book of reference for medical officers in connexion with their sanitary duties, but also as a practical guide to officers of the line with respect to the care of troops over whom they have control. We may say at once that he has succeeded.

The first two chapters dealing with the Selection and Development of the Recruit contain a lot of well arranged information of an interesting and instructive character. Speaking generally, it may be emphatically said that where the physical standard required of army recruits is high the rates of sickness and death are proportionately low. It is a platitude to state that the health efficiency and mobility of an army greatly depend upon the careful selection of its material in the first instance but the close correlation which exists between the physical and moral development of races and individuals is too often apt to be regarded in the abstract rather than from the concrete and practical point of view. Contrary to the opinion generally entertained the standing army of the United States contains no large proportion of men of foreign birth. Statistically speaking about 70 69 per cent we are told are born in the United States. As in our own service recruits for the regular army of that country are in time of peace mainly drawn from the lower walks of life and the labouring classes, but in time of war and particularly in the volunteer forces all sorts and conditions of men moved by patriotic or military ardour and various motives are attracted to the service. Speaking generally it is found that the better classes of society are also better physically, except in the matter of vision for imperfect or defective eyesight increases with ascent in the social scale. (And here we may parenthetically remark that considering the great advances which have been made in modern arms and warfare the test standard of vision laid down for British officers cannot be regarded as too exacting, on the contrary it should probably be raised or the use of glasses permitted.) As regards the age at which the recruit should be taken—well we must in this country take him when we can get him, but the age at which the British soldier of naturally sound constitution may for the moment be regarded as of the greatest value is probably from 25 to 30 or possibly 35 years of age and Dr Johnson was probably not far wrong in his impromptu birthday lines to Mrs Thrale about life declining after 35 years. Soldiers of all armies during their first two years of service it has to be borne in mind seem to be disproportionately liable to typhoid fever especially those of our own army in India. The chapter on the selection of recruits is full of ancient saws and modern instances drawn from all sources of recent military experience, and that on the development of the recruit which is illustrated by plates showing the stages of improvement under physical training is excellent.

The March in Campaign forms the subject of the next chapter. It may be profitably read and referred to by medical and combatant officers alike but we pass over it to speak more fully of Chapter IV. This deals with Water, not so much in connexion with its bacteriological and chemical side as from a military service and practical sanitary point of view. The subjects of quantity sources storage and supply are first considered then drinking water in its relation to disease and the methods employed for determination of its quality, together with its chemical and bacteriological examination and purification are passed in review. The only safe standard to be aimed at is to secure at first a pure source of water supply free from all risk of contamination and then to keep the water so until it reaches the lips of those drinking it. Unfortunately, this cannot always be done especially in time of war. The subject in connexion with water borne diseases as everyone knows is a very big and a most difficult one to deal with from an army service point of view. The dissemination of the specific micro organism producing typhoid fever is ordinarily—though probably not exclusively—accomplished through the agency of contaminated water. The suddenness of the outbreak and the simultaneous occurrence of a large number of cases are indicative of an epidemic of typhoid fever attributable to water infection whereas in camp epidemics due to defective sanitation the onset is usually much more gradual. Assuming the typhoid bacillus to be veritably and indeed the specific cause of that fever it must have a far wider distribution in nature than is commonly supposed. The elimination of typhoid bacilli by the kidneys affords a ready means of the spread of the disease which has not yet sufficiently engaged the attention of medical officers. The more extended application of Widal's tests and the Ehrlich diazo reaction with Horton Smith's investigations and Sanarelli's experimental results open out new fields for inquiry. The provision transport and exclusive use of boiled water on field service are apparently impracticable. Pasteur Chamberland filters have not proved altogether satisfactory or sufficiently durable for campaign work. The subject of the prevention of enteric fever in war it must be confessed bristles with practical difficulties at the present time. Many more or less elaborate forms of apparatus for the sterilisation of water by heat have been designed. Vaillard and Desmaroux's apparatus for example is a very ingeniously contrived and effective steriliser, but it has not all its parts accessible for repair and is too costly and intricate in construction and not sufficiently portable for field service. The Waterhouse Forbes water steriliser is very fully described and highly commended at pages 138 *et seq.* of the volume under review. It is portable can be taken apart and made into bundles so that two such sterilisers can be carried on a pack mule, and it is alleged to be very efficient and economical. As the result of exhaustive experiments the Waterhouse Forbes apparatus was officially recommended as being superior to any other filters or water sterilisers submitted for trial in the United States and as being well suited for the abundant supply of sterile cold water to troops. A sample of the new and improved apparatus should we think be obtained from America and tried in this country and also in South Africa at the present time. Chapter XX., on Diseases of the Soldier (page 674 *et seq.*) may well be read in connexion with the chapter about Water for in it will be found a very full and up-to-date notice of typhoid fever. The subject of malaria is of course dealt with in connexion with the results of recent researches in proof of the Manson Ross theory. The author does not discard water as a possible cause or vehicle of malaria. What has now we think, to be ascertained is whether the malarial parasite has any extra corporeal phase of existence which has yet to be discovered.

The fifth chapter on the Ration of the Soldier is an admirable one and no other work with which we are acquainted contains the same amount and variety of information. Passing over Military Clothing and Equipment we come to a chapter on Camp Sites and Camps and the sanitary administration of the latter and then on to the Barracks Quarters and Hospitals in which the subjects are practically handled and accompanied by numerous illustrations. Touching the question of hospital tents we may call attention to the Munson hospital tent (page 900) and refer-our readers to a brief description of it as adopted by the medical department of the United States army and shown at the Pan-American Exposition at Buffalo (*vide* The Lancet, Sept. 14th, 1901, p. 750). Ventilation in connexion with cubic space and superficial area, heating and lighting, and the influence of these on health and disease, are adequately and judicially considered. We are glad to notice that in the barracks now being constructed in the United States provision will be made for an allowance of from 660 to 720 cubic feet per head, but it is very properly added that it should not be assumed that no further improvement is desirable in this respect. "From what has been said establishing the floor space at about 85 feet per man and the height of the room at from 11½ to 12 feet, it follows that the amount of cubic air space which should be available is, in round numbers, 1000 cubic feet." This amount agrees with theoretical standards based upon the results of a considerable number of experimental observations. Cubic space is a matter largely governed by financial considerations, but these have not the same prohibitive effect in a rich country with a relatively small army, which is the position of the United States. The allowance in the British army of 600 cubic feet per head is, it is needless to say, too small to admit of anything like 3000 cubic feet of fresh air per head per hour passing through without making the barrack-rooms altogether too cold and draughty. We do not find any allusion as to the introduction of the cubicle system into the soldiers' barracks of the United States army, about which much has been said of late, but these observations have, of course, a very direct bearing on the question, and on the problem of ventilation under the new and altered conditions which will be brought about by that system.

The chapters on the Disposal of Excreta, Sewage, and Refuse, and the Personal Cleanliness of the Soldier, do not call for special notice: it is sufficient to say that they are good and full of information. Chapters XIV. and XV. on Military Mortality and Morbidity and on Diseases of the Soldier respectively strike us as being unusually full and complete and well put together, and the same may be said of the chapters on Disinfection, the Habits of the Soldier as Affecting Efficiency, and the pertinent and useful remarks on Sanitary Inspections. The author's remarks on the prevalence of venereal disease in armies are very sensible and well worth reading. There is, after all, as it seems to us and as we have always maintained, nothing which has any real influence on the incidence of these diseases except sanitary control of them.

The work is profusely illustrated, well indexed, and well printed and got up. It is scarcely necessary to add, for it will be seen from all we have said, that we have formed a high opinion of this book. It is what it pretends to be, and the author has spared no pains in his efforts to collate and to analyse information from all available sources and to bring it up to date, while putting his own stamp upon it by setting forth at the same time his own views and the results of his own experience. We can heartily commend it as a very valuable, if not indispensable, book for army medical officers and all interested in the theory and practice of military hygiene. Captain Munson and the Medical Department of the United States Army are to be congratulated on its appearance.

Handbook of Public Health, Laboratory Work, and Food Inspection. By O. W. Andrews, M.B., B.S. Durh., D.P.H. Camb., Staff Surgeon R.N. London: Baillière, Tindall, and Cox. 1901. Pp. 292. Price 7*s.* 6*d.*

This work is divided into three parts, a classification based upon lectures delivered by the author to the surgeons under instruction at the Royal Naval Hospital, Haslar. In Part I. the main points to be observed in the inspection of fish, flesh, and fowl intended for human food are considered. The characteristic feature of this part of the work is a series of excellent illustrations of fishes (poisonous and non-poisonous). The inspection of carcasses and of meat and a discussion of the humane methods of slaughtering occur in the section dealing with parasitic diseases. Part II., which is the longest section in the book, is devoted to the chemical analysis and examination of water, air, milk, and other foods, wines, and the like. So far as we have examined the analytical processes described we have found them reliable. This is due to the author's evident familiarity with the literature dealing with modern methods of analysis. He quotes methods of food analysis which have appeared from time to time in the *Analyst* and refers to the work of many well-known analysts. Microscopic illustrations are given of the various starches. In the chapter on Wines the author draws largely from the report of The Lancet Commission on Sherry which appeared in The Lancet of Oct. 29th, 1898, p. 1135. Part III. contains a description of the relationship of meteorology to disease and the author includes an account of meteorological phenomena sufficient for the needs of the student studying for the Diploma of Public Health. It includes a description of the meteorological instruments used in weather forecasts. The bacteriological portions of the work are somewhat brief, but the author has selected certain essential points for fuller treatment, as, for example, the tuberculin test and the bacteriological examination of water. The book has been written with an evident regard to the needs of those studying for public health diplomas and great care has been taken to make the compilation reliable. We believe that the medical student will find Dr. Andrews's hand-book on public health work an excellent practical guide.

Handbuch der Toxikologie. Von Professor A. J. Kunkel. Volume II. Jena: Gustav Fischer. 1901. Pp. 1100. Price 12 marks.

The handbook under review constitutes the second and final volume of Professor A. J. Kunkel's important work on toxicology. As in the first volume an arrangement has been adopted which is founded on the chemical constitution, and not on the special action of the toxic bodies with which this work is concerned. In view of our limited knowledge as to the relationship between chemical constitution and physiological action this is probably the only feasible and rational arrangement, although in the interests of toxicologists, who may have frequent occasion to refer to these pages for information on matters of detail, an alphabetical arrangement in dictionary form would have had much to recommend it. Although the author has experienced considerable difficulty in assigning to their respective chemical departments, and in defining the exact differences between, the closely related decomposition products of exogenous and autochthonous origin it must be admitted that the distinctions have been satisfactorily enforced without unnecessary overlapping or repetition of facts.

In view of the interest which, owing to the researches of Mott and Halliburton, has been recently centred on the subject of the choline group of ptomaines or leucomaines, we naturally turn to the pages devoted to this subject by Professor Kunkel. Choline itself is chiefly considered as a product of extraneous decomposition, being one of the first bodies to appear and one of the first to disappear in the process of prolonged decomposition of nuclein containing substances of animal origin. It has a wide distribution in the animal body, but is chiefly regarded as originating from the contents of the bowels. Its *spontaneous* appearance apart from the action of bacteria is admitted, though its pathological significance in the chemistry of nerve degeneration is not referred to and its toxic action is stated to be very feeble To the physiological action of peptones considerable space is devoted, while the numerous false deductions which have been based on their supposed toxic action are fully considered, and where necessary refuted Taking all available evidence into consideration, the author inclines to the belief that the majority of the early experiments which were conducted to establish their toxic properties were unreliable for the reason that the presence of toxalbumin was not excluded. Pure peptones free from albumoses, when injected directly into the circulation, apart from causing an immediate fall in the blood pressure, exercise no seriously toxic influence on the animal function, and further, if the injection of peptones be confined to the descending aorta so that some time must elapse before the injected material can reach the chambers of the heart, even this temporary fall in blood pressure can be avoided It seems that peptones are rapidly destroyed or organised as they circulate in the blood stream The poisonous properties of other bodies belonging to the albumose or proteose group, including snake poisons are exhaustively dealt with, but little or no reference is made to any possible chemical or molecular distinction by which it may be eventually possible to differentiate between the toxic and non toxic varieties This speculative side of the question although a matter of extreme interest to physiologists is perhaps justly regarded as outside the scope of a handbook of toxicology On the other hand, we cannot help thinking that such important bodies as albumoses should not have been left without some sort of a definition

We make no attempt to give an adequate idea of the amount of ground covered by the second volume of Professor Kunkel's "Toxicology" Practically speaking, all bodies containing carbon in their elementary composition and possessing toxic properties of any importance find a place in this very exhaustive and accurate work of reference. The index has apparently been compiled with great attention to detail, so that those who seek special information can do so without previous knowledge of the chemical group to which the body they are searching for belongs

---

The Physiological Action of Drugs By M S PEMBREY, M A., M D Oxon., Joint Lecturer on Physiology in Guy's Hospital Medical School, and C D F PHILLIPS M D LL D Aberd., Examiner in Materia Medica and Therapeutics in the University of Aberdeen London Edwin Arnold 1901 8vo Pp 100 Price 4*s* 6*d*

ALTHOUGH the authors of this manual modestly describe it as an elementary work the experiments given in it which should be carefully executed by the student will form a good introduction to the investigation of the action of medicines upon the living human subject The most earnest antivivisectionist can hardly take exception to operations done and medicines administered to frogs the brain and spinal cord of which have been destroyed and it is now known that much information can be gained from such mutilated animals The introductory experiments explain the method of pithing a frog and the mode of applying electric and thermic stimuli to the muscles and especially to the heart Numerous tracings are given showing the effects on muscular contraction and on the cardiac beats of the administration of distilled normal saline solutions of tap water saline solutions, and of solutions in distilled or tap water of alcohol, ether, chloroform chloral hydrate, strychnine hydrastin, morphine, caffein curara nicotine cocaine, pilocarpine, muscarine, veratrine, digitalin physostigmine and extract of suprarenal gland The tracings show the effects described in the text very clearly The book will prove useful if the student remembers that whilst the action of the above named drugs on nerve muscle and heart is satisfactorily demonstrated by the tracings, these tracings do not explain the peculiar action of the several drugs on the animal economy, for example no attempt is made to say why hydrastin acts as a purgative or morphia causes sleep The tracings lead the physiologist to draw inferences that are probably correct but they do no more

LIBRARY TABLE

A Short Manual of Inorganic Chemistry By A DUPRÉ Ph D, F R S, F I C, F C S, and H WILSON HAKE Ph D F I C, F C S *Third edition.* London Charles Griffin and Co, Limited 1901 Pp 406 Price 9*s* —The authors adhere to the dry as dust method of teaching chemistry presenting general principles before facts and maintaining that general principles can be clearly comprehended by a student who has no previous knowledge of chemistry whatever That may be so in isolated examples, but on the whole we do not believe this to be the best plan. The student's interest in chemistry should be first aroused and his powers of observation stimulated, and this is best done by the practical rather than the mathematical method Surely a student is attracted to his subject better by what he observes than by what he reads. Experiments are more likely to engage the interest of the majority of students than hieroglyphics on the black board Besides many experiments may be conducted showing approximately that definite quantities are concerned in the various inter actions as in double decomposition and thus the way to theory is opened up This method seems to us naturally to invoke the spirit of inquiry in the beginner, chemical fundamental laws will come to his assistance later The authors' method will doubtless appeal at once to students of a mathematical bent but in most classes this kind of student is not the rule The descriptive matter in the book before us is excellent and up-to-date The plan under which the elements and compounds are described is also good A note on the Physiological Action of the Elements and their Compounds is an important addition to a book intended evidently for medical students The feature of the work is the adoption of the periodic system of classification a step which is scientifically correct Considering the limitations of the book the authors have made the most of their opportunity, presenting a short manual bristling with facts, and in which practical and theoretical considerations are intelligibly put

Studies from the Royal Victoria Hospital Montreal Vol I No 1 (*Ophthalmology* I) By W GORDON M BYERS M D, assistant oculist and aurist, Royal Victoria Hospital, Demonstrator in Ophthalmology McGill University Toronto Carveth and Co 1901 8vo pp 82.—The subject of the first essay of the first volume of 'Studies from the Royal Victoria Hospital of Montreal' is on the Primary Intradural Tumours of the Optic Nerve or Fibromatosis Nervi Optici and constitutes a valuable addition to our knowledge of a rare form of disease Dr Byers himself has had two cases under his care the details of which he gives and has collected notices of no less than 153 cases described by different authors in our own and in continental literature Such tumours appear to be more frequent in women than in men and to be often due to traumatism or to infectious febrile disease In regard to their pathological character a large proportion were of the nature of sarcoma myxoma myxo-sarcoma fibro-sarcoma and myxo-fibroma which collectively represent nearly 60 per cent of all the cases Whilst removal is to be recommended every effort should be made to keep the globe in position We have much pleasure in recommending this essay as a typical monograph and great credit is due to Dr Byers for his valuable contribution to ophthalmology.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 21, 1901.

The Outbreak of Small-pox in London.

THE reappearance of small-pox in London, and its prevalence in St. Pancras at the present time, lead us to consider the probability that for some years we shall be liable to more frequent visitation from this disease than we have experienced for a considerable period. It is now 30 years since the great epidemic of 1871, which extended over Europe and especially affected London, killing in that year as many as 7912 persons in the metropolis. In 1872, 1877, and 1878 the death-rate from small-pox exceeded the mean of the period 1841-99 and again in 1881, 1884, and 1885, since when only in 1893 did more than 100 deaths from small-pox occur in any one year. There is much reason for thinking that we need not anticipate during coming years any such mortality as that which occurred in 1871, the causes of which have been made clear by Mr. W. H. POWER's study of the distribution of the disease in the neighbourhood of the metropolitan small-pox hospitals. The lesson which the Principal Medical Officer to the Local Government Board taught the medical profession and the public, and which led to the removal of cases of small-pox out of London, will not be forgotten, and London will not experience again such a visitation as that of 1871. Nevertheless, the period has come when small-pox may be expected to be more prevalent, recurring at intervals with increasing severity until a maximum is reached, after which the disease will again decline—as after 1871.

Last year small-pox showed a tendency to increase, some 70 persons in London being attacked. Its prevalence and distribution during the present year can be learnt from the tabular statement which the weekly returns of the Registrar-General now contain. During the first six months 14 cases were notified and they occurred in 10 of the metropolitan boroughs. Since the middle of June cases have occurred in London in each week, a marked prevalence manifesting itself in St. Pancras in the week ending August 24th and extending into the neighbouring boroughs of St. Marylebone and Holborn. The number of cases notified in London in that week were 22, followed by 60 in the following week, then by 27 in the week ending Sept. 7th, and by 53 in the week ending Sept. 14th. The original focus appears to have been a group of streets occupied by poor persons on the borders of St. Pancras and St. Marylebone, but the disease is now extending into more remote districts. The fatality of the outbreak cannot yet be stated, but it is known that London has received small-pox from Paris and that the disease has appeared in the hæmorrhagic form; and in this connexion it will be recollected that the small-pox of 1871 appeared to have travelled from the continent. And while London is now free from the risks of aggregation of cases of small-pox in its midst it has a new danger to reckon with in the number of young children who, since the appointment of the Royal Commission on Vaccination, have escaped the protection which vaccination affords. For some years, so far as the published figures show, from a quarter to one-third of the children who have been born in London have "not been accounted for" in respect of vaccination. In St. Pancras and St. Marylebone the number of children not known to be vaccinated fails to reach this proportion, but in the unions of Bethnal Green, Hackney, Mile End Old Town, and Shoreditch the proportion has been far greater, the returns of the Local Government Board for the year 1897 showing 71·7 per cent. "not accounted for" for Bethnal Green, 70 per cent. for Hackney, 63 per cent. for Mile End Old Town, and 67·4 per cent. for Shoreditch. The extension of small-pox into these districts might therefore be attended with considerable loss of child life. A further danger is undoubtedly due to the fact that the comparative absence of small-pox from London in recent years has prevented many of the younger medical practitioners from having experience of its appearances, and in its mild form it is not unlikely to escape recognition. Indeed, we understand that an unrecognised case of small-pox from Paris in the early summer is believed to have been responsible for a hæmorrhagic case which received infection from this source. This obvious danger has led to a suggestion by Mr. WYNTER BLYTH that the Metropolitan Asylums Board should publish illustrations of actual cases for the information of those practitioners who have not had experience of the different appearances of the disease.

The machinery which now exists for the protection of the community against small-pox by vaccination is calculated to cause difficulty by leading to neglect of vaccination during periods of absence of small-pox, while there will be greater need of the services of the public vaccinator during times of prevalence. The efficiency with which the vaccination of persons in invaded houses and localities can be effected is certain to be prejudiced by the fact that there is still separation between the health authority and the vaccination authority. The medical officer of health may bring to the knowledge of the vaccination officer every case of small-pox which is reported to him, but the vaccination officer is not under his control or that of the authority he serves, and between such act on his part and the appearance of the public vaccinator on the scene there is room for failure. The concentration in the hands of the health authorities of all the functions concerned in the prevention of small-pox is, we think, needed. Similarly an intimate relation between the health authority and the board school authority is urgently required. The part played by school attendance in giving opportunity for the spread of infectious disease, of diphtheria, scarlet fever, and measles, is now well-recognised, and the increase in the number of unvaccinated children may not unlikely lead to school attendance acting in a somewhat similar manner in the distribution of small-pox. The health authority can now require the exclusion from school of particular children and, if it is thought necessary, the closing of a school. The interest of the school authority is undoubtedly to prevent any interruption of the education of the children in their charge, and they could in respect of small-pox do much in the direction of prevention if they would allow the condition of the children as to vaccination to be ascertained at the school. It is stated that a request that they should do this has been made to them, but as yet no reply has been received. While in Germany the enforcement of the vaccination law practically hangs on school attendances, in England no such position exists. The difficulty indicates the need for some closer alliance between the health and education authorities; and it is thought by some possible that this will eventually be effected by the creation of the county councils as education authorities. In the meantime we sincerely trust that the London School Board will do everything in its power to give facilities for the stamping-out of the small-pox which threatens London at the present time, and which not unlikely may spread from London to other parts of the country.

◆

The Work of the Government Laboratory.

THE Government Laboratory has developed into one of the most active institutions under official control. Judging from the last annual report which has just been issued it would be difficult to imagine any administrative work of a more miscellaneous character than that carried out under the direction of the principal Government chemist, Dr. T. E. THORPE. The Admiralty, the War Office, the Board of Agriculture, the Board of Trade, the Home Office, the India Office, the Local Government Board, the Post Office, Trinity House, and the Inland Revenue Office (one of the most important of all consultative departments from a State point of view), all freely seek the advice of the Government chemists in Clement's Inn. The number of samples referred to the Government Laboratory under the Sale of Food and Drugs Act, and involving analytical inquiry, is a comparatively insignificant item in the programme of work. During the past official year not more than 78 samples were so referred, and 72 per cent. of the certificates of analysis furnished by public analysts were upheld. This function of the Laboratory has not been lost sight of, but the far-reaching nature of the duties now undertaken by the institution make it appear comparatively unimportant.

The events of the year included between March, 1900, and March, 1901, conspired to throw considerable pressure upon the work of the Government analysts. The continuation of the war, for example, easily accounts for the increased number of samples that were submitted by the War Office, a regular weekly supply of samples having been examined which involved the temporary increase of the Laboratory staff. It is satisfactory to know that the systematic examination of samples of food and drink, representing supplies delivered by contractors for army use, has had an excellent effect in raising the average quality of such articles, besides in some instances lowering the cost. Many of the samples thus submitted proved to be adulterated, amongst them being butter, baking-powder, cocoa-paste, mustard, jam, and marmalade—we do not exhaust the list. The India Office has also submitted samples for control to the Government Laboratory. As illustrating the advisability of such a step the following may be quoted. The India Office ordered 23,000 tins of condensed milk on one occasion which was conditional on the milk containing not less than 10 per cent. of butter fat. On examination of several tins the percentage of fat was found to range from 8·71 to 9·12. Considerable analytical work was done on behalf of the Local Government Board in connexion with public health matters during the year, while in two directions extraordinary help has been rendered by the institution to the country. The Departmental Committee appointed to investigate the use of Preservatives in Food had the assistance of the Government chemists. Dr. THORPE states in the report that the labours of this Committee are approaching conclusion and we believe that a provisional report has been drawn up. Again, the appointment of the Royal Commission on Arsenical Poisoning, which had its origin in the disasters caused by the use of poisoned beer in Manchester and one or two other centres, threw extra work this year upon the Government Laboratory. The results of the examination of a great number of samples of brewing materials, wort, and beer were communicated to the Royal Commission, of which Dr. THORPE was a member, and these results were of the greatest assistance to the Commissioners. Further experiments of a valuable kind have also been conducted in the Government Laboratory during the past year as to the solubility of lead frits used in glazing. Later a Departmental Committee was appointed by the Board of Agriculture to inquire into, and to report upon, regulations for the sale of milk and cream, and the results of a great number of analyses of these products conducted in the Government Laboratory were available for the consideration of this Committee. Information of a valuable kind relating to the methods of analysis was thus obtained, and standards of quality or composition in regard to milk were ultimately recommended which passed into lawful requirements on the first day of this month.

It is evident from all this that something more is done in the Government Laboratory than the mere routine demanded by the great Government departments of Customs and Excise. In these latter departments, however, most excellent work is being done in detecting and checking ingenious but fraudulent practices. Of course, this work of scientific detection is conducted principally for safeguarding Revenue interests, but this often means also the protection of the consumer. For example, there are certain ingredients the addition of which to tobacco is deemed illegal; and of 32 fluids examined this year, comprising oils, flavouring substances, and preservative liquids, it was reported that 13 could be legally used in manufactured tobacco, but that 19 were illegal. In one glaring instance the manufacturers of a preservative solution were fined the full penalty of £200 for supplying the illegal fluid to a tobacco manufacturer. Of 61 samples of tobacco taken from manufacturers for analysis 17 were found to be genuine. 11 of the adulterated samples containing either liquorice or glycerine. Rather more than one-half of the samples contained salicylic acid used in the "liquoring" water. In one instance a seizure was made at a factory where the acid was found ready for use with tobacco and penalties were imposed amounting to £240. An ingenious design to give tobacco the appearance of being moist seems lately to have grown into practice. It was observed that occasionally some specimens of roll and cake tobacco which from a physical examination seemed to contain moisture in excess of the legal limit actually contained moisture considerably below that limit (30 per cent.). The apparent anomaly was soon explained by the fact that the appearance of such tobacco was due not to excessive moisture but to oil. The oil used was olive oil. It is interesting to consider in what way the addition of olive oil or salicylic acid to tobacco would affect the smoker. Conceivably the smoke from such tobacco would contain injurious members of the acrylic and phenylic series. It is satisfactory, however, to know that a legal limit in regard to the addition of oil has been made, while salicylic acid (which is probably employed to prevent mildewing or fermentation) has been interdicted altogether. In the returns recording the tobacco exports the figures are remarkable in showing how increasingly popular is the practice of smoking cigarettes, while it is also shown that the consumption of British-made cigars is increasing abroad. The large increase in the number of consignments of tobacco exported "on drawback"—i.e., without having paid duty as imports on this side—is due to the shipments for the use of the troops serving in South Africa. We are reminded here to notice another ingenious expedient of avoiding the demands of revenue. The plan in question is had recourse to in connexion with the exportation of medicinal tinctures, flavouring essences, and perfumes "on drawback," but it has been brought to light and effectually checked As is well known, the rate of duty on the spirit present in tinctures, essences, and perfumes is very small as compared with that on spirit intended, or capable of being used, for potable and other purposes. To avoid payment of this higher rate of duty orders are occasionally sent from abroad to include in the consignment considerable quantities of alcohol coming under the category of tinctures and perfumes or essences which are so slightly coloured or flavoured as to be available for other purposes. By a similar device it is attempted to supply wood naphtha for methylating purposes or for "spoiling" alcohol, but which proved to be much too pure to be suitable for the purpose.

The total number of analyses and examinations made at the Government Laboratory in the past official year was no less than 72,422. equal to about 230 samples per working day. This is a most creditable performance and one which we may safely attribute to the energy and skill of Dr. THORPE and to his well-known administrative capacity. To him largely has the present excellent organisation and equipment of the new Government Laboratory been due. And in this record of the past year's work may be found evidence of the fact that Dr. THORPE finds time, in spite of the great number of technical operations conducted, to undertake pure scientific inquiry. As illustrations of this may be mentioned the investigation on the exact composition of lead silicates for glazing ware, and a research directed to the isolation and recognition of the poisonous principle in yew trees.

The Death of President McKinley.

IT has been said that no injury of the skull is of so little moment that it can be neglected, and that none is so severe that it need be despaired of, and this is almost equally true of wounds of the abdomen. And as this fact influences our prognosis at the moment of infliction of an abdominal wound, so it should influence our prognosis until health is fully restored. In no part of the body are sinister surprises more likely to be met with than in the abdomen. Patients who have progressed, and are progressing, most favourably cannot be considered to be out of danger until they have ceased to be patients. The dangers and pitfalls are many. Great as is our knowledge to-day of the injuries of the abdomen, many as are the resources of the surgeon, skilful as may be his operations, yet there are elements in any case of abdominal injury which may render in vain all his knowledge, his resources, and his skill. A fatal result after an abdominal operation for injury may ensue from many causes. In the forefront stands sepsis; this is by far the most common, and therefore the most important, cause of death in these cases. Infection may have occurred, and indeed generally does occur, at the time of infliction of the injury, or at all events before the surgeon sees the patient; or it may take place in the course of the operative procedures: or later. Only second in importance to sepsis comes shock. The nervous supply of the abdominal viscera is so extensive that comparatively slight injuries may be followed by such great depression of the heart's action and of the vaso-motor centre that the patient cannot rally. Shock is of chief importance for the first few hours after the injury, but for many days, or even weeks, the vital powers are depressed, and this depression if not sufficient of itself to cause death, may lend its aid to other harmful influences. Hæmorrhage, too, is a common cause of death in these cases; and even if the patient survives, the depression resulting from loss of much blood may be felt for months or years. When in an injury of the abdomen a hollow viscus is perforated a further danger appears. The extravasation of the contents will not merely introduce further sepsis, but will also add the irritation resulting from the chemical nature of the extravasated material. Among so many rocks on which he may be wrecked it is not strange that the surgeon cannot always steer his patient into safety. To the surgeon practised in abdominal surgery all these facts are well known, and he will be the least surprised at the result which may follow in any abdominal case who has himself performed operations on the abdomen.

President McKINLEY was a man, past middle age indeed, but still in good health Abstemious in living and devoted to study, he lacked physical exercise. He was shot by a revolver, and the bullet entered the abdominal cavity, passing through both walls of the stomach, injuring the pancreas slightly, tearing the upper end of the kidney, and lodging in the deep muscles of the back The official report of the medical men attending the necropsy stated:—

> "The bullet passed through both walls of the stomach near its lower border. Both holes had been found to be perfectly closed by the stitches, but the tissues around each hole had become gangrenous. After passing through the

stomach the bullet passed into the back walls of the abdomen, hitting and tearing the upper end of the kidney. This portion of the bullet track was also gangrenous, the gangrene involving the pancreas. There was no sign of peritonitis or disease of other organs. The heart walls were very thin. There was no evidence of any attempt at repair on the part of nature, and death resulted from gangrene which affected the stomach around the bullet wound as well as the tissues around the further course of the bullet. Death was unavoidable by any surgical or medical treatment and was the direct result of the bullet wound.

In considering the reason or reasons of the *fatal issue* of the case we may leave out of consideration the bullet itself; where it was lodged it could do no harm and time and the patient's strength would have been wasted in searching for it. The injury to the kidney also appears to have been of but little moment and need not be further considered. The damage to the pancreas was probably unimportant, though it has been suggested that the escape of pancreatic juice may have caused, or assisted in causing, the "gangrene" of the bullet track described in the account of the necropsy. This is hardly likely as the "gangrene" was found also in the wounds of the stomach wall. The peritoneum and the wounds of the stomach remain to be considered. There seems to be no evidence that at any time was there any peritonitis, and this was confirmed by the *absence of leucocytosis, the blood having been examined* several times during the patient's life. It does *not appear* from the account of the necropsy that any bacteriological examination was made of the peritoneal wall or fluid. Still we shall probably not be wrong in assuming that no peritonitis was present. The empty condition of the stomach prevented extravasation occurring, at least to any great extent. The wounds in the stomach wall were sutured with a minimum of delay and apparently no leaking occurred. How shall we account for the "gangrene" of the margins of the wound? There is no need to suspect any poisoned bullet, and the supposition that such a bullet was used was probably due to the fervid imagination of a reporter, not unwilling to pile horror upon horror. It is by no means rare to find after revolver *wounds of the stomach wall that but little attempt at* repair is made. This is to be attributed in part to the local action of the gastric juice and in part to the patient's general state. The pathological condition has been met with before and will doubtlessly often occur again. Surgery does all of which it is at present capable. The wound is carefully sutured and the peritoneal cavity is aseptic, and yet healing does not occur. The bruised gastric wall has not sufficient vitality to recover and it makes no effort.

The favourable prognosis which was put forth at first was so far justified that in some cases recovery might have followed, but the issue hardly comes as a surprise. The injuries were terrible, the patient was no longer young, and the circumstances were such as to produce even in a man of *iron* courage the maximum of shock. If we may venture to criticise any portion of the treatment we feel inclined to suggest that the feeding by the mouth was somewhat in excess of that which is usually considered advisable. But while we say *this* we *know that to the* brilliant surgeons and experienced physicians around President MCKINLEY's bed there may have been indications for the bolder treatment impossible to be disregarded. In short on a careful review of the whole case we feel justified in saying that surgery did its best; the sad result is to be ascribed to the lack of vitality of the tissues themselves.

Annotations.

"Ne quid nimis."

CHRONIC INVALIDISM IN WOMEN

THE frequency with which the condition of chronic invalidism known as neurasthenia is met with at the present *time is a matter of much interest*. *Dr Playfair* has done well in calling attention to this most important class of cases in his lecture upon Chronic Invalidism in Women published in the present issue of THE LANCET. As he truly points out it is only of recent years that the real nature of the disease has been recognised and unfortunately even to-day it not uncommonly happens that a well marked case of nervous exhaustion is sent to the gynæcologist because the medical attendant regards some local condition as the source of the whole mischief. This is more likely to happen when the practitioner's experience of general practice has not been of long duration and we do not see how it can be prevented. The complete ignorance of students with regard *to such cases is well known. The condition is one that* receives but scanty notice from the lecturer on medicine while the obstetric physician has too much to treat of in his short course of lectures to devote any time to a subject which is really no part of his particular branch. The result is that many students enter upon their career with but vague conception of what a case of neurasthenia really is and with no idea of the proper mode of treating such a case when they meet with it. To Dr Playfair more than to any other teacher is due the *credit of having devoted much* attention to these cases and he was the first to bring before the notice of the profession in this country the brilliant results to be obtained by the judicious use of the Weir-Mitchell method of treatment. Unfortunately, the method has been misapplied and abused, and the result is that some men are inclined to condemn it unduly and hastily. That it is capable of giving good results there is abundant evidence to show, but as Dr Playfair points out it requires to be supplemented by qualities *on the part of the* medical attendant and the nurse in charge which are only too often absent. The expense, too, inseparable from the treatment is in many instances a bar to its employment. *Fortunately* the great majority of such cases belong to the better classes but it is a mistake to suppose that neurasthenia or chronic invalidism is never met with amongst poor women; it does occur and in such instances the prospect of cure is of the most remote character. Dr Playfair has clearly pointed out the main conditions that tend to produce this disease. The stress and worry of modern life have much to answer for, and although it is true that most of such strain falls upon the male members of the community, yet there are many women who have to bear their full share and indeed often more than their full share of the troubles of life. Mental worry is a most important etiological factor and we are inclined to think that the fact that many women, owing to the disproportion of the sexes in this country, are condemned to the task of earning a livelihood and *of fighting* their own battle in life is a cause that cannot be overlooked. Whatever the etiology may be the condition when recognised is not difficult to treat properly and the results are most satisfactory. *Dr Playfair* is perhaps inclined to be a little optimistic about the chances of relapsing cases. Many patients are unable to carry out the course of after-treatment which he recommends and returning to their homes long before they should resume their life in the midst of the very surroundings which originally produced their break-down. We may well hope, in view of the greater stress laid upon the physical culture of young girls in the present age and the undoubted improvement in their physique that has resulted, that the number of cases of neurasthenia may diminish. But even here it is necessary to utter a note of warning. Women are too apt to forget that the pursuit of various athletic exercises calls for an amount of what we may call preliminary training upon the part of the muscles which in the case of many young girls is entirely wanting. Unless, like their young brothers, they have been brought up to exercise their muscles from their earliest days, the attempt to take an active part in the many manly games that are so in vogue at present at the large girls' schools in this country not uncommonly leads to disaster. The great benefits that will result from the pursuit of various outdoor games is undoubted, but at the same time the pleasure and excitement of the game and a healthy desire to emulate the feats of their older and often stronger companions lead many young girls, unless judiciously restrained, to tax their strength to an undue degree and to acquire only harm from what in moderation could not fail to be of the greatest possible benefit to them. Physical over-exertion as well as mental over-strain are equally to be avoided if cases of nervous exhaustion are to be banished from the catalogue of diseases.

A PROVINCIAL MEDICAL LIBRARY.

THE library of the Bristol Medico-Chirurgical Society, together with that of the Faculty of Medicine of University College, Bristol, forms the Bristol Medical Library with altogether over 20,000 volumes. Mr. L. M. Griffiths, M.R.C.S. Eng., is the honorary librarian, and at the last annual meeting of the Library Association he read an interesting paper entitled, "Some Things of General Interest in the Bristol Medical Library," a reprint of which paper has been forwarded to us. The paper deals chiefly with Bristol as a health resort and the reputation which it gained owing to the Hotwells at Clifton. The medical profession seems to have been rather at a discount, for, according to an author named Owen, who wrote a book about the Hotwells, "it were well if those gentlemen's fees were all the ill that sometimes attend their officious services." The water of the well was much affected by the great earthquake at Lisbon, and people, thinking that the end of the world was upon them, "flew to the churches, where prayers were offered to avert the apparent approach of their destruction." The water of the Hotwells was exploited in London by Dr. D. W. Linden who also practised in Clifton during the summer. He published a book on the subject which was prefaced by a poetical panegyric on himself written by a friend. This "poem" was in the very best style of "The Loves of the Plants," or perhaps we should say "The Loves of the Triangles." Mr. Griffiths quotes the following:—

"And when no more these *Earthly Streams* afford
That Health to him, to others they restor'd;
When Galen's Sons shall his sad Loss deplore;
His Skill, in Consultations, reap no more.
When the *Castalian* Nymphs, in Mournful Tale,
The *Universal Friend's* Departure wail;
Seraphs, to deck them, and emblaze his Fame,
Shall o'er the Skies bespangle *Linden's* name;
In glittering Characters, it there shall shine,
A *Constellation* in the *Watry* Sign·
While, bath'd in Bliss, he wafts at full Content,
In *Heavenly Streams*, above the Firmament."

This is something like advertisement. Among other interesting matters Mr. Griffiths gives a list of the holidays granted to Government officials at the Custom House and elsewhere. It is a curious list, containing such diverse "feasts" as All Souls' Day, the landing of William of Orange, the landing of George I., and the burning of London. It is of interest to find All Souls' Day officially commemorated at the end of the eighteenth century, and if we remember right the day is still commemorated in the Oxford almanack. In 1798 Dr. Beddoes opened a pneumatic institution for the treatment of disease by inhalation where his assistant was Humphry Davy who while at work discovered the properties of nitrous oxide. We hope that Mr. Griffiths will continue his researches into the treasures of the Medical Library, for he has a keen eye for the curious.

METROPOLITAN HOSPITAL SUNDAY FUND: ILLNESS OF MR. CUSTANCE.

AT a special meeting of the council of the Metropolitan Hospital Sunday Fund, held at the Mansion House on Sept. 11th, the Lord Mayor presiding, a letter was read from Mr. Henry N. Custance stating that on account of failing health he tendered his resignation of the office of secretary which he had held for 28 years. The council decided to give him six months' further leave of absence from Nov. 1st next, in the hope that at the expiration of that period he would be able to resume his work. Several speakers, including Sir Sydney Waterlow, who as Lord Mayor in 1873 founded the Fund, bore testimony to the admirable manner in which Mr. Custance had performed his duties.

THE CHEAP PISTOL.

THERE is an aspect of the murder of President McKinley which we sincerely hope will not be lost sight of by the Legislature either in our own country or in the United States. Only a few weeks ago[1] we called attention to the number of crimes committed in England with the cheap pistol, pointing out that it is of no use either as a sporting weapon or as a protection against violence, but is only a source of danger to citizens and a temptation to the reckless and weak-minded; while we protested against the idea that the trade in such articles was one worthy of protection or consideration. A more lurid illustration of our arguments could not have been found than the recent hideous, meaningless, and miserable crime at Buffalo. We have seen no details as to the nature of the weapon employed by Czolgosz, as to how he obtained it, or what he paid for it, but that it was what we denounced as a "cheap pistol," such as can be bought without let or hindrance for a few shillings by any schoolboy, lunatic, or criminal in this country or in the United States, we have no kind of doubt from what happened. Two shots were fired within a foot or two of the victim. One bullet did not even reach the body; the other, encountering soft tissues only, did its deadly work of laceration among them, without having sufficient energy imparted to it to pass out. We have no information, as we have said, concerning the way in which the murderer bought his weapon, but we have no hesitation in asserting that had the only revolver allowed to be sold or carried in the United States been a weapon of heavy calibre, such as is issued to the army or the navy, and had such a weapon, moreover, been subject to an appropriate duty when sold to a civilian—even without further restrictions being placed upon its purchase—either it would have been beyond the means of Czolgosz to obtain it, or he would not have been able to possess it without exciting remark. Such a weapon, moreover, would have been difficult to carry and almost impossible to draw and handle in the presence of detectives without attracting immediate attention. With precisely such a cheap weapon as we have denounced our own monarch's life was attempted upon the continent shortly before his accession, and now we have seen in the death of the President of the

---

[1] THE LANCET, July 27th, 1901, p. 220.

United States what such a weapon can do when chance favours it, absolutely useless as it is for all lawful purposes. We call the attention of those who frame our laws to the dangers which beset those who occupy exalted positions; dangers largely increased by the fact that any would-be criminal, sane or insane, can buy a more or less effective firearm for the price of an old song without the most casual and superficial question being asked as to his identity or his purpose. The law, however strengthened and amended, may not be able entirely to prevent criminals from carrying weapons concealed on their persons and from using them if they will take the risk of doing so, but we need not allow such engines of destruction to be within the reach of every purse, nor need we let their unrestricted exposure for sale constitute an incentive to crime for those too weak to resist the suggestion.

SCENT.

A CONSIDERABLE difference of opinion exists in regard to the propriety of using scent upon the person. The practice is of oriental origin and had for its original object the desire to make the person pleasing to the opposite sex. Not a few quaint customs, however, have turned out in practice to have other influences than were originally designed, and this may prove to be the case with the personal use of perfume. It should be remembered that the basis of all perfumes is an essential oil of some kind, derived either naturally from flowers or leaves or artificially by a synthetic process. In either case the essential oil is a powerful antiseptic and possesses disinfecting properties not less in degree than those of carbolic acid itself. As is well known, the essential oils absorb atmospheric oxygen, forming an unstable compound easily lending oxygen for the work of purification. Pine oil, eucalyptus oil, and turpentine act readily in this manner—a fact which probably accounts for the salubrity of the air of pine forests and eucalyptus woods. The use of scent by many women is excessive, and by men is looked upon as effeminate—a prejudice that we confess to sharing—and yet the question naturally arises, As we study our environment to please the eye by colour and natural effects and to please the ear by musical notes, why should we not make similar endeavour to please the nose by agreeable and fragrant odours? Each sense may suffer offence and there is no reason why each sense should not be equally defended in this regard. And the use of scent on the pocket-handkerchief, which is where we commonly find it, is calculated to exercise a higher office than merely to please the sense of smell. The handkerchief may easily prove a source of infection, for it is made to be the common receptacle of secretions from the nose and mouth, and the employment of an antiseptic handkerchief is perfectly consistent with the dictates of common bacteriological evidences. The liberal use of scent on the handkerchief is calculated to make it antiseptic and to destroy the germs in it, owing to the action partly of the spirit of the scent and partly of the essential oils dissolved in the spirit. Before, therefore, we condemn the persons who use scent upon the handkerchief for practising a foppish or luxurious habit we should remember that they may actually be doing good to their neighbours by checking the distribution of infectious materials.

AUTO-EXTIRPATION OF THE LARYNX.

THE amount of self-mutilation of which the mentally unsound are capable is very remarkable. It is doubtful if any more striking example of this has ever occurred than a case described in the *Comptes Rendus* of the Forensic Medicine Section at the recent Paris Congress. A woman, 42 years of age, went with a neighbour to the public baths. While they were waiting for admittance the friend suddenly missed her and, not succeeding in finding her, returned home. The neighbour went to the woman's rooms but found them closed and knocked at the door in vain. After nearly two hours the neighbour, learning that the woman had been seen to return, went and told the husband, who entered the room through a window. The woman was found alive, lying in a pool of blood with her throat cut. A medical man arrived about half an hour later and began to dress the wound, when to his astonishment he found that the larynx was missing. He searched the room for it and found it some feet away, and near it was the table-knife with which the deed had been done. The hæmorrhage had ceased and a few stitches were put in. The patient was sent to a hospital and died some eight or nine hours after she had cut her throat. There was not the slightest doubt that the case was one of suicide. The portion removed consisted of the entire larynx, a part of the thyroid gland, the anterior wall of the pharynx, and the front and upper part of the œsophagus. The carotid arteries, the internal jugular veins, and the vagi were not wounded. The larynx showed numerous cuts, but none of the skin of the neck had been removed with it. A small cut on the terminal phalanx of the left middle finger induced Dr Szigeti, who reported the case, to believe that the woman with a knife in her right hand incised the skin and cut across the upper end of the larynx and with her left hand she tore it away. The importance and interest of this case can hardly be over-estimated. It is important to recognise that these extensive injuries can be self-inflicted, for a charge of murder in such a case might easily receive much support from the apparent impossibility of such an injury being suicidal. In this way the case compares well with one recorded in our columns last week by Mr. C. A. J. Wright of Leytonstone.[1] A paper in this number of THE LANCET by Mr. F. G. Harvey on Excision of the Larynx is of interest when read in connexion with this case; for the paper shows the difficulty of the operation which this unfortunate woman managed somehow or other to perform upon herself.

ISOLATION HOSPITALS.

A CIRCULAR has recently been addressed by the Local Government Board to the councils of boroughs other than county boroughs and to urban and rural district councils calling their attention to the provisions of the Isolation Hospitals Act of 1901, which has recently received the Royal assent, and which has amended the Act of 1893, giving increased facilities to local authorities for the provision of isolation hospitals within the areas under their care. The need for legislation of this class, and for emphasising the powers which it gives, is well illustrated by a report which lies before us of a recent meeting of the Leominster Rural District Council, at which Mr. H. Jones, the medical officer of health of the district, asked for information as to the steps which he would be expected to take in case of an outbreak of infectious disease among the hop-pickers, such as had, so he informed the council, already taken place in two other districts in the county—in one of which a child had had to be isolated in a barn. There being no isolation hospital in the Leominster Rural District the chairman was empowered to confer with the borough authorities who appear to have a hospital for infectious cases under their control; and no doubt by the aid of the new Act, and with the assistance of the Local Government Board's circular, a practical conclusion will be arrived at. It is obvious that in any district, whether liable to the incursion of hop-pickers or not, epidemics of infectious diseases demand better accommodation for patients than barns. The Isolation Hospitals Act of 1901, among other topics dealt with, enables district councils and joint boards, which have provided hospitals under the Public Health Act of 1875, to transfer these hospitals to the county council, and gives directions with regard to the expenses incurred by the county council in connexion with the transfer. It further provides for the contribution by county councils to isolation hospitals provided by local authorities under the Public Health Act of 1875, whereas hitherto county councils have been enabled by the Isolation Hospitals Act of 1893 to contribute only to hospitals instituted under this last-named Act. Fresh facilities are given to hospital committees to enable them to obtain temporary accommodation for patients when there is an unusual strain upon their existing resources, and various technical difficulties which have hitherto puzzled or obstructed hospital committees are cleared away. Progress in matters affecting the public health is gradual and the result of statutes followed by amending Acts is a body of regulations which are somewhat complicated and difficult to grasp, even by those constantly in touch with them; but the progress is welcome in whatever form it is embodied. Even as a temporary measure and in extreme need the use of such a building as a barn strikes us as highly undesirable, owing principally to the fact that it must present almost insuperable difficulties to those charged with disinfecting it.

"NEXT TO GODLINESS."

CONSIDERING the extent to which the benefits of fresh air have been exploited of recent years in connexion particularly with the cure of phthisis, it might naturally be expected that in public places a state of affairs would not now be tolerated which is contrary to the recommendations of medical authority. We are all perfectly aware of the necessity for free ventilation. We understand why indiscriminate spitting is an abominable danger, and how close rooms and stuffy omnibuses and over-filled railway-carriages increase the chances of infection even for healthy persons. Moreover, we know that in the presence of an infected person, as where one member of a family is the subject of pulmonary tuberculosis, a constant supply of pure air in plenty is a paramount necessity for the health of those who are bound to live under the same roof as the sufferer. So much, then, being matter of common knowledge, it is little short of marvellous to see in what kind of atmosphere this enlightened public is content to confine itself at certain times. A visit to the courts of law, or to churches of every denomination, might well lead to a belief that to these places resorted a class of beings for whom fresh air was a dangerous thing to be carefully excluded, and that only in a thick, carboniferous, organically tainted atmosphere could the brain of man discern truth through the mazes of legal bewilderment or his soul respond to the solemn claims of a religious service. There can be no greater mistake than to neglect the conditions of atmosphere in which mental labours, be they legal or of any other kind, are undertaken. The weariness, the headache, the indifference to food or inability to assimilate it, that are apt to follow a day in the courts or a few hours in a church are often the result of a foul atmosphere. The theatre and the church, viewed from a low, but practical standpoint, have much in common. In matters of ventilation, however, the modern theatre has advanced in a way which religious communities might imitate with advantage. There can be nothing unholy in a pure atmosphere. The first clergyman who devotes a "collection" to the construction of efficient ventilation for his church will deserve well of his congregation, and will most assuredly take an effective step towards increasing its numbers. How many women, we wonder, are subject to fainting attacks and to headaches in church and nowhere else? There must be thousands who absent themselves for no other reason. A place of worship in which the air was fresh and pure would be as strong an ally to the claims of religion as can well be thought of. Doctrine may ask us to mortify the flesh; she nowhere demands that we should also pollute our lungs.

THE PROTECTION OF PARTURIENT WOMEN AND THEIR OFFSPRING.

WE have received the account of a scheme adopted by the Medical Guild of Manchester for the protection of parturient women and their offspring. This scheme provides for putting within the reach of the poorer classes the assistance both of a trained nurse and of a qualified medical practitioner, and is recommended as a basis for future legislation. Provision is made for the supply by the local authority of trained, examined, and registered obstetric nurses free of all charge, the nursing being supplied to women living in the district, whose circumstances shall justify it, during their confinement and during the puerperal period. At the same time the local authority is to have the power to issue to each suitable applicant for a nurse a note requisitioning the services of a medical man; this note when accepted by a medical practitioner to constitute an engagement on his part to render such assistance as may be necessary in the confinement, the note to be redeemed by the local authority from the medical practitioner at a rate to be determined hereafter. The local authority is to have the power to determine the suitability of applicants. We welcome a scheme put forward in the honest attempt to deal with a question of the first importance in medical practice, but even while doing so we cannot pretend to think that the Medical Guild of Manchester have solved the problem. To compare the greater with the less, just as poverty cannot be abolished by an Act of Parliament saying that it shall no longer exist, so no clause in a scheme, however carefully drawn, can wipe out the midwife—at any rate, not yet. For good or for ill she is a present-day institution. It is, of course, better for a woman to be attended by a medical practitioner and a nurse than by a midwife single-handed. At the same time any scheme which attempts entirely to abolish the class of midwives is almost assured of failure. It is, and will be, impossible to prevent women from employing midwives in place of medical men if they so choose, and even if a law were passed to stop such a practice—which legislation we shall never see—it would be impossible to enforce it. Such a scheme as the one that we are now considering could only apply to those women whose condition would entitle them to the services of a nurse and medical man free of all charge. Surely such a measure, even if it were not abused (as it very likely would be), would lead to the pauperisation of a large number of persons, since all the women attended under such circumstances would be practically receiving outdoor relief at the expense of the ratepayers. It seems to us quite certain that any measure which would tend to increase the already heavy poor-rates, and which would throw an increased burden upon the taxpayers, is bound to be rejected by the public. And it is the wives and children of the public whose welfare is in question. It has been urged with some weight that the present system by which large numbers of women are attended in their confinements for nothing by medical students in connexion with the large maternity charities of our medical schools tends directly to pauperisation of the women. It certainly does. Knowing that in case of need almost everything will be supplied to them, they in many instances make little or no provision for their approaching confinement, and the necessity for thrift to provide for the expenses which under ordinary circumstances must attend such an event is entirely absent. The public, however, through the medical profession, directly benefit by the hospital midwifery. It is necessary to train medical students, and by the care of such cases, under the supervision of first-class surgeons and physicians, the recruits to our ranks learn their obstetric medicine. But it is quite another matter when we have to consider a proposal which would encourage improvidence all over the country. The expenses of such a scheme as the one formulated by the Manchester Medical Guild would be very great, since the local authority would have to pay not only the salary of the nurses, but also the fees of the medical practitioners. Unless, too, it were associated with a law totally to prohibit the employment of midwives—which we regard as an impossibility—it would of necessity fail, since there would still remain a considerable class of women, not suitable applicants for the relief, who would prefer the cheap services of a midwife to the more expensive ones of a medical man. The scheme is similar in its main outlines to that proposed by Dr. McCook Weir in his Bill brought before the profession in 1898. It will be necessary, however, in our opinion, for the Manchester Medical Guild to furnish further details as to its practical working before it can be considered to be within the range of possible politics We hope that they will do so, for the subject is enormously important, and discussion from all points of view, especially when based upon a thorough design to deal with the problem, cannot fail to be useful.

DIPHTHERIAL INFECTION FROM HEALTHY PERSONS.

THE existence of diphtheria bacilli in the throats of healthy persons is a great difficulty in preventing the spread of the disease, a fact which has often been pointed out and discussed in these columns. Dr. F. P. Denny, bacteriologist of the local Board of Health, states that in Brookline, near Boston, U.S.A., during an epidemic of diphtheria, when a child was taken ill with the disease, cultures were taken from the throats of those who sat near them in school, and diphtheria bacilli were found in the throats of some who were perfectly healthy. He also refers to an outbreak of diphtheria among a milkman's customers three weeks after two of his children were sent to hospital with diphtheria. Cultures were made from his household, when three healthy men, two of whom milked the cows, were found to harbour diphtheria bacilli which were virulent to guinea-pigs The following case, recorded in the *Boston Medical and Surgical Journal* of August 29th by Dr. F. W. White, shows how healthy persons may be a source of infection. A child, aged two years, living in a tenement house in Boston, had membrane on the tonsils and the diphtheria bacillus was found in the throat. The illness began on Dec. 12th, 1900. nder antitoxin convalescence was rapid. But for the following three months cultures were obtained from the throat which were virulent to guinea-pigs. On Feb. 1st, 1901, the rooms were fumigated On March 1st the culture from the throat was negative, the house was fumigated, and the child was released from isolation On March 3rd cultures from the child's throat and from the throat of two out of four persons exposed to him—a boy aged four years and a girl aged 18 years—yielded diphtheria bacilli. The two latter had not been ill at any time during the three months Two children—a boy aged seven years and a girl aged four years—came to the house just after the release of the patient and were exposed to the other children for a day or two and then returned home. Within five days the girl developed a moderate attack of diphtheria. She was not attending school at this time and was not exposed, as far as is known, to any other source of infection. The moral of these cases is that a single negative culture from the throat is not sufficient to guarantee the absence of diphtheria, and that the throats of those who come in contact with patients suffering from diphtheria should be examined for the bacilli before they are allowed to mix with healthy persons. No doubt the latter rule is somewhat a "counsel of perfection." But at least it is quite possible for persons who are in close contact with diphtheria patients to avoid the society of children.

VITAL STATISTICS OF THE JAPANESE NAVY.

THE medico-statistical report of the Japanese navy for 1897, being the fifth annual issue and the latest published, shows an apparent increase of sickness together with an actual decrease of mortality. In previous reports only severe cases of disease were included, but in that for 1897 all absences from duty on medical or surgical grounds are entered in accordance with the practice now prevalent in most of, if not all, the navies of the world. The average strength of the Japanese navy in 1897 was 14,964 officers and men, an augmentation of nearly 2000 on that of the preceding year. This total was made up as follows: officers, 315; subalterns, 2251; sailors and stokers, 12,056; servants, 342. The average sick- and death-rates for the twelvemonth were 822 5 and 6 88 respectively per 1000 of strength Each case entailed absence from duty during 24 7 days, but only about one-fifth of the whole number were admitted to hospital, the others being treated in quarters or in detention rooms. Amongst the officers the sick-rate was only 225·7 per 1000, and about half the cases were treated in hospital. Out of 9710 vaccinations, primary and secondary, 4138, or 44 per cent, were successful. During the year the food ration underwent considerable modification, the following ingredients being diminished. biscuit, preserved meats and fish, beans, flour, dry vegetables, dry fruits, pearl barley, sugar, oil, salt, and fat; while the following were augmented: bread, fresh meat, fresh fish, rice, fresh vegetables, and barley. The result of this measure was highly satisfactory, the mean weight of the men having been nearly 15 ounces higher in 1897 than in 1896, and four pounds higher than the average of the preceding 13 years

ST. BARTHOLOMEW'S HOSPITAL AND CHRIST'S HOSPITAL.

IN our issue of July 7th, 1900, p 43, we gave some account of a special Court of Governors of St. Bartholomew's Hospital which was held to consider the situation arising out of the negotiations with the authorities of Christ's Hospital as to the purchase of the whole or part of the site owned by the latter institution. It was then agreed that a portion of the site, indicated in a plan which we have published[1] and in area about one and a half acres, should be acquired for the sum of £117,000 A Bill for this purpose was accordingly presented to Parliament and received the Royal assent during the last session The medical staff of the hospital, however, had in November, 1899, urged upon the treasurers and almoners their conviction that the whole site of Christ's Hospital should be acquired, and they have now reiterated this conviction in a circular sent out to the body of governors and dated August, 1901. It is probable that a special Court of Governors will be held to consider the circular and what measures can be taken for the acquirement of the site. Of course the whole question is one of money Naturally the almoners of Christ's Hospital want as much for their site as they can get and the value of the property is doubtless very great. St Bartholomew's Hospital is sorely in need of increased space not only for present requirements but for future expansion. The surgery is totally inadequate for the work carried on therein, the College is composed of inconvenient and insanitary little houses, the nurses' quarters are as inconvenient as possible, while the post-mortem room and the mortuary accommodation are (to put it mildly) a disgrace to an institution of such a position and world-wide fame. While it would be unwise for the hospital to cripple itself by running into debt, yet we may hope that the charity of the kingdom—for St. Bartholomew's, like other London hospitals, is by receiving patients from all parts of the kingdom a national rather than a local institution—will be able to supply funds for the purchase of the whole site. Here is an opportunity for Mr. Carnegie to help the foundation where those famous Scotchmen, Pitcairn and Matthews Duncan, worked.

---

[1] THE LANCET, August 11th, 1900, p 403

"JAMESON PORTRAIT FUND."

IN response to the expressed desire of many officers it is proposed to present Surgeon-General J. Jameson, M.D., C.B., late Director-General Army Medical Service, with his portrait. Duplicate copies, it is understood, will be painted for the Royal Army Medical Corps messes at Netley and Aldershot—if funds permit. Such a presentation would express the high esteem in which Surgeon-General Jameson is held by his brother officers, and would form a suitable recognition of his great services to the Royal Army Medical Corps and to the army. It was during his tenure of office that the Royal Army Medical Corps was constituted, and on that ground alone it is most desirable that his name and personality should be handed down in portrait form to future generations of army medical officers. A committee for the furtherance of this object has been formed in London and the consent of Surgeon-General Jameson to sit for his portrait and to nominate an artist has been obtained. Messrs. Holt and Co., 3, Whitehall-place, London, S.W., have kindly consented to receive subscriptions, which should be marked for "The Jameson Portrait Fund."

THE CLOTHES OF DEAD SOLDIERS.

THE case of typhoid fever in which infection was held to be due to the wearing of apparel sent home from South Africa which had belonged to a soldier who had died from typhoid fever gives rise to a question with which the military authorities have probably not been widely confronted before. The facts of the case were roughly these. A man serving in the Fusiliers died at Krugersdorp from typhoid fever. His kit was sent home to his family, one of whom, a son, unpacked it and found the clothes "soiled, just as they had been taken from his father's body." We quote a contemporary's account. The son wore the boots at once and the socks after they had been washed, and in little more than a week fell ill. After some days he was admitted to St. Bartholomew's Hospital, where he was certified to be suffering from typhoid fever. The medical officer of health to the Southwark Borough Council prepared a report for presentation to the council, and is reported to have added that the case is sufficient to show that the practice of sending home the kits of men who have died in this way is undesirable, and a possible source of danger to the public health. With this opinion we agree. Whether in this particular case the clothes were to blame or not, as the incubation period would be unusually short, does not affect the question of principle. It is, no doubt, a laudable issue of sentiment and justice to send the dead soldier's family whatever belongings he had with him. Such kindness, however, will be a doubtful benefit if disease lurks in the returning property. The clothes in which a man arrives at the hospital where he succumbs to an infectious disease should certainly be destroyed. The alternative of efficient disinfection is scarcely practicable on active service. Compensation might well be made to the deceased's family, and would be a more unequivocal recognition of his services. Discrimination and hard-and-fast regulations are uneasy companions. If it is the military rule for the kits of men who die abroad to be returned to their families there is probably little difference made according to what was the manner of the man's death. The representations of a medical officer would not influence the department whose duty it is to send back kits. A kit to the department would be a kit whether it took typhoid fever or anything else with it. What is wanted is a change of the hard-and-fast regulation.

FIFTH INTERNATIONAL CONGRESS OF PHYSIOLOGY.

THE Fifth International Congress of Physiology was opened on Sept. 17th in the physiological laboratory of the University of Turin, under the presidency of Professor Angelo Mosso. The assembled physiologists were formally welcomed by the President in a short address. Sir Michael Foster, K.C.B., M.P., Secretary of the Royal Society, was then elected honorary perpetual president. Professor Fano, Professor Fredericq, Professor Grützner, and Professor Sherrington were appointed general secretaries. More than 200 physiologists from various countries were present and 186 communications were announced. A reception was given by the members of the Academy of Medicine of Turin on Monday evening and an exhibition of physiological apparatus was also opened on Monday in the Anatomical Institute which adjoins the physiological building. The Congress is continuing in session till Saturday, Sept. 21st.

THE general secretary asks us to inform the members of the Thirteenth International Congress of Medicine that the printing and posting of the general volume and of the 17 records of the sections are now entirely finished. Any member entitled to the volumes and not having received them is requested to notify the publishers, Messrs. Masson and Co., 120, Boulevard Saint Germain, Paris, before the end of the year.

THE annual dinner of the past and present students of the Westminster Hospital will be held on Friday, Oct. 4th, at the Hotel Cecil, at 7 for 7.30 P.M. Mr. Charles Stonham, F.R.C.S. Eng., will be in the chair.

THE annual dinner of the past and present students of St. Mary's Hospital will take place at the Whitehall Rooms, Hôtel Métropole, on Thursday, Oct. 3rd. Brigade-Surgeon-Lieutenant-Colonel A. B. R. Myers will be in the chair.

THE RECENT OUTBREAK OF PLAGUE IN CONSTANTINOPLE.

(BY THE BRITISH DELEGATE TO THE OTTOMAN BOARD OF HEALTH.)

THE following is a brief *résumé* of the recent history of plague in Constantinople. It will be recalled that the first case of the disease in this city occurred in the first week of January last. The patient was a boatman in the employ of a custom-house official and it was suggested that he might have come into contact with some infected goods passing through the custom-house and so have contracted the disease. But, as a matter of fact, no satisfactory explanation of the source of infection in his case was forthcoming. Plague was undoubtedly present in Smyrna at the time, and as the man was in communication with friends in Smyrna it seemed possible that the infection came in some way from that town. Whatever its source there can be no question that the infection of plague did reach Constantinople at that time. So far as was known only one case (a fatal one) occurred then and it was not until after the lapse of nearly four months that it was followed by other cases. The first of these patients was taken ill on April 27th. He was a Greek, aged 36 years, who was employed in a certain macaroni factory in Galata (the portion of Constantinople lying to the immediate north of the Golden Horn). There ensued another period of two months' duration without any known cases, but towards the end of June and the beginning of July a small group of fresh cases occurred of some epidemiological interest. A youth, aged 18 years, named Yanni, fell ill on June 23rd. He was employed in a grocer's shop (*épicerie*) and lived in Galata at no great distance from the macaroni factory above mentioned. An Italian, named Antonio Pola, was attacked on June 27th and was admitted to the Italian hospital on July 4th. He also came from Galata, where he lived in a street not far from the *épicerie* in which Yanni was employed. Then, on June 30th, a woman named Despina developed symptoms of plague. She lived in Cassim Pasha, a quarter of the town also on the northern shores of the Golden Horn, but at some distance from the quarter of Galata where the previous cases had occurred; on inquiry, however, it was found that the patient had been staying in Galata with her mother, who lived in a house at no great distance from the macaroni factory. Finally, on July 2nd a man named Mihali fell ill with plague; he lived in yet another quarter of the town, but was said to have been in frequent relations with a person inhabiting the infected quarter of Galata It will be seen that the four cases occurring between June 23rd and July 2nd could be, to some extent, traced to a particular quarter of the town and that that quarter was in the neighbourhood of a macaroni factory · one of the employés of which had been attacked with plague in April. It has been suggested that this factory was in some way the original source of the infection in this group of cases, and to account for the appearance of the infection there it has been thought that it might have come from abroad in the flour which forms the basis of the macaroni prepared in the factory. This flour is, it is said, always imported from France or Italy; none of it comes from Egypt or other countries where plague has recently been prevalent It has also been ascertained that the s s *Niger*, which came to Constantinople last year with some cases of plague on board, landed here some sacks of flour and several cases of macaroni Hence a theory has arisen that the infection of plague which has caused the recent outbreak here was imported by the s.s *Niger* in August of last year. It will be of interest, therefore, to recall the facts connected with the [illegible] on that vessel. The *Niger*, [illegible] arrived in Constantinople [illegible] was given *pratique*, but a few hours later an Armenian boy, a third-class passenger, was found to be ill, and the illness proved to be an attack of plague. A second case developed after the ship had left Constantinople for the quarantine station of Clazomene, and some subsequent cases occurred on her voyage from Clazomene to Marseilles. It was clear that the *Niger* was rather extensively infected with plague, even at the time of her arrival in Constantinople, and it is undeniable that 160 passengers had been allowed to leave her there, and that a considerable amount of merchandise had also been landed from her. Subsequent measures of surveillance of the landed passengers and of disinfection of the merchandise were also arranged for, but there could be no complete assurance that those measures, however thoroughly carried out (and thoroughness in the mathematical sense was in the nature of things impossible) would destroy all traces of infectious material that might have reached the shore. There was therefore no little probability that the infection of plague did reach this country a year ago. But there is very little to show that the recent small outbreak in Constantinople was the consequence of that importation and not of some fresh one. It has not yet been proved (and it probably now never will be proved) that the macaroni factory was the real source of infection in these cases or that any of the sacks of flour or cases of macaroni landed from the *Niger* ever reached that particular factory.

[illegible] cent outbreak. On July 12th a [illegible] med Mirza Ali, was attacked [illegible] 14th respectively two Jews living in the Balata quarter of Stamboul developed the disease. These appear to have been the first cases in Stamboul itself—i.e., the portion of Constantinople south of the Golden Horn Stamboul occupies the original site of ancient Byzantium and of the city of Constantine and his successors. It is roughly a triangle, bounded on the north (or north-east) by the Golden Horn, on the south (or south-east) by the sea of Marmora, and on the west by the remains of the splendid wall built (mainly) by the Emperor Theodosius to guard the city from land attack on the only side where land attack was possible. Balata is a quarter of Stamboul very near the north-west corner of the triangle where the walls meet the shores of the Golden Horn. No fact has yet been brought forward to show how the infection of plague was brought from Galata, where it first appeared on the north shore of the Golden Horn and at its eastern extremity, to Balata on its southern shore and at its western extremity. Two other cases occurred in connexion with this quarter, both patients being children and nieces of one of the Jews first attacked. They developed the disease at Haidar Pasha, on the Asiatic side of the Bosphorus, near Scutari, but they did so immediately after their removal from the house in Balata in which their uncle had developed (and died from) plague

A third *foyer* of the disease may have been a connecting link between the Galata and Balata *foyers* already described. This was at Baluk Bazar on the southern or Stamboul side of the Golden Horn, and close to the great bridge of boats which connects Galata with Stamboul. In this bazaar an Albanian poultry-seller, named Youssouf, fell ill on July 22nd This date is nine days later than that of the first known case in Balata, and it is only by supposing that earlier cases, unknown to the authorities, occurred in Baluk Bazar that the latter can be regarded as a link between the *foyers* at Galata and Balata. This case of Youssouf is of importance. After his removal to hospital 17 persons who had been in "contact" with him were by orders of the municipality, shut up in the house under military cordon for a period of 12 days. They were not permitted to leave the house for any purpose whatever, food was passed in to them through the windows. There were no latrines of any kind in the house, which is situated in one of the closest and dirtiest quarters of the city. The results of this measure recall the pictures drawn by writers in the seventeenth and eighteenth centuries, when "shutting up" infected houses was the almost universal practice. After 12 days of imprisonment under conditions of physical discomfort that it is not pleasant to think of, the 17 "contacts" were released, and it was found that two of them were [illegible]

that he died a few [illegible]

occurrence of these [illegible]

at such an advanced stage that one patient was already moribund, speak eloquently of the thoroughness of the "thorough disinfection" which was supposed to have been practised in the house, and of the strictness of the "strict medical surveillance" under which the imprisoned "contacts" were supposed to be.

The remaining cases of plague may be briefly mentioned. Some time in July a Greek groom in the employment of a dragoman of the Russian Embassy developed plague; how he contracted the disease is not known. On July 21st a patient was admitted to the Greek Hospital from Ak-Serai, a quarter of Stamboul far removed from those already mentioned, and died the same night. On July 25th one of the municipal disinfectors, Haralambo by name, fell ill; he had disinfected a plague-infected house 12 days previously and lived in a street in Pera where hitherto no plague cases had occurred Some time in July also a child living in a room below that originally occupied by Despina (the case mentioned above) developed plague Then, on July 30th, a fireman on board the s s *Benghazi*, a boat constantly plying between Constantinople and Moudania, was attacked, and there is little question that he "caught" the disease in Constantinople Finally, after an interval of some 16 days without any known case, a fresh one occurred on August 19th, the patient being a Greek employed and living in Galata.

As is usually the case when plague has appeared in a new locality there has been a controversy as to whether it is in fact the plague or some other disease But the clinical and bacteriological data in most of the cases above cited have left no room for doubt that the plague has gained a foothold in this city.

The facts hitherto elicited in regard to unusual phenomena among rats in the infected quarters of the city are very imperfect But as the result of inquiries made from trustworthy observers it appears that during the months of May, June and July there was a marked mortality among the rats in Galata One of the patients, Mirza Ali, whose name is mentioned above and who fell ill on July 12th, volunteered the information that between July 6th and that date he had himself caught in his hands and killed a number of rats, which he estimated at from seven to 10 These rats appeared to be very ill and they had escaped from the mouth of a drain situated near the shop where he worked. It is also stated that a number of dead rats were seen in the shops and sheds and on the landing-stages which fringe one side of the Galata-Stamboul bridge, and also in the Baluk Bazar already mentioned. In recent weeks there seems to have been an almost complete disappearance of rats from Galata—and it is possibly by a migration of these animals that the infection has been carried to the other quarters of the town.

In regard to the measures taken in Constantinople to deal with the plague, it is to be observed that the responsibility for these lies with the municipality and not with the International Board of Health. The latter exists to try to keep disease out of the country; when disease has once entered the country it is dealt with by the Turkish authorities. But the Board of Health has always been regarded as the first authority in the country on sanitary matters; it has usually been consulted on the occasion of epidemics and has frequently lent some of its members or delegates to sit on mixed committees formed to deal with outbreaks of disease. This has been the case on the present occasion. On April 30th an Iradé was issued by the Sultan requesting the Board to coöperate with the municipality in this matter and to draw up a series of recommendations as to the measures necessary to be taken. On May 4th a series of recommendations, prepared by a sub-committee of the Board and approved by the whole Board, was ready. It is unnecessary to refer in greater detail to these recommendations, as they have unfortunately remained a dead letter. The measures taken have been taken almost exclusively on the initiative of *the municipality, and it cannot be denied that they* have proved very inadequate. Thus, for example, of the five hospitals originally intended to have been built in different parts of the town, not one is yet in existence, and there is at the moment of writing no special hospital in or near Constantinople to which a case of plague could be removed. During the early days of the outbreak, and pending the construction of such hospitals, the Board of Health placed at the disposal of the municipality its "lazaret" at Monastir-Aghzy, on the Asiatic side of the Bosphorus, near the Black Sea end of the strait. But this lazaret was never intended for such purposes, its object being the isolation of cases of infectious disease brought by ships from other countries, and not the treatment of cases of disease originating in Constantinople itself. Several of the earlier cases of plague and of the "contacts" of those cases were removed to this lazaret, but later the Board decided that it could no longer be used for this purpose, as it might at any moment be required for its own legitimate purpose. Even this was not sufficient to rouse the municipality to the urgent need of preparing hospitals, and when the horrible condition above described of the 17 "contacts" in the Baluk Bazar case was discovered (conditions which the German delegate to the Board described as analogous to those of the Black Hole of Calcutta) there was no hospital ready to which they could be sent. On grounds of humanity alone, and without waiting to summon the Board, the vice-president felt compelled to give his consent to their immediate transfer to the lazaret at Monastir-Aghzy, and this was done. The Board has, however, since (on August 6th) re-affirmed in the most positive manner its refusal to admit any more plague cases or "contacts" to this lazaret, and there is consequently, as already stated, no plague hospital at this moment to which a case of plague could be removed. One municipal hospital is in course of construction at Omour-Yéri, on the Asiatic shores of the Bosphorus, about two-thirds of the way towards the Black Sea. When I visited it quite recently this hospital was very far from completion. It presents many serious faults of construction, and is inconveniently (and even dangerously) far from the town for the removal of persons seriously ill from plague. But it is something to be grateful for that anything in the nature of a plague hospital will be ready in the course of the next two or three weeks.

Constantinople, Sept. 10th.

PRINCE OF WALES'S HOSPITAL FUND.—The Frank James Memorial Home for Seamen at East Cowes, Isle of Wight, has been offered to the Prince of Wales's Hospital Fund for London on condition that the fund will select a London hospital in need of a convalescent home, preference being given to a hospital for sailors. In addition to this offer by the trustees of the home, Messrs. Arthur and William James have undertaken to endow it to the extent of £10,000.

FRENCH AND BRITISH POSTAL MEDICAL SERVICES: A COMPARISON.

(BY OUR SPECIAL COMMISSIONER.)

IT is satisfactory to note that the description recently published of the measures taken by the French Government to prevent the contamination of the post-offices and the spread of tuberculosis among the employés has produced some effect on this side of the Channel.[1] In any case, the Association of the British Postal Medical Officers are now advocating the adoption in England of the same precautions as those just introduced by the French Government. These are embodied in a report recently issued by that association dealing with the prevalence of tuberculosis. But the reforms initiated by M. Millerand, as Minister of Commerce and Post and Telegraphic Services, do not deal only with the conditions that favour the spread of phthisis; he has also remodeled the medical service of his department; and it may be equally useful to compare these alterations with the conditions that prevail in England. Such a comparison will at once show that in France details, special needs, and difficulties, have been carefully studied, thought out, and in most instances provided for. In England a more rough-and-ready method has been adopted and but little ingenuity displayed. Indeed, the Post Office authorities have not hit on any more original plan than that of imitating on a somewhat liberal scale the methods of medical aid clubs and friendly societies. The main difference rests in the fact that the postal medical officers receive *8s. 6d.* per annum per employé on the books, while friendly societies and clubs generally pay only *4s. 4d.* In France the postal medical officer receives extra remuneration when there is extra work to be done. Attendance at the surgery or consulting rooms may be considered as regular work, and though the number of patients who call varies from day to day the time for which the medical officer has to be on duty, and to hold himself ready to give advice, does not vary. Therefore he receives a fixed salary for this portion of his work, which in Paris amounts to £60 a year. 16 medical officers divide between them the 22 *arrondissements* of Paris. As there are some of these districts in which very few postal servants can afford to live it was possible, in these cases, to give two districts to one medical officer. But, on the other hand, the work to be done in visiting patients in their own homes is an unknown quantity. It may be light or very heavy. The conditions of the state of public health are constantly varying; therefore the medical officers are paid per visit. The fee given is 2 francs for each visit, which, as fees go in France, is about the equivalent of the traditional 2*s.* 6*d.* paid in England by the poorer class of private patients. In high class practice the 20-franc piece, or 16*s.*, replaces the guinea given in England, and though 2*s.* 6*d.* is equal to 3 francs 10 centimes there is this further difference, that the French practitioner never supplies medicines. Consequently a 2-franc fee in France for a visit without the giving of medicine is to some extent an equivalent for a half-crown fee in England for a visit and medicine. But, further, it should be noted in regard to these visits that the postal medical officer in France has only to attend to those postal servants who live in his own district, and in Paris this would not necessitate the going of any long distance.

The most serious defect of the British system is that the 8*s.* 6*d.* per annum has to meet every conceivable circumstance that may arise. If a serious surgical operation is needed this must be performed. If an elaborate chemical or bacteriological analysis is required all this must be done by the postal medical officer, who therefore requires to be not only a good all-round general practitioner, but to be able to perform any surgical operation and to be more or less a specialist in bacteriology. Needless to say that the acumen and logic of the French mind would not tolerate such an absurdity both of theory and practice. It is fully realised that a general practitioner is not likely to have made a special study of bacteriology or be capable of performing with a master hand the most varied and complex surgical operations Therefore operating surgeons are also appointed who are called in when operations have to be performed. These surgeons receive no salary. They are paid 5 francs (or 4*s*) per visit and according to a fixed tariff for each operation An official circular giving these details was issued on May 19th 1900 The fees vary from 15 francs for opening, draining of abscesses, and other minor operations to 200 francs for the more serious operations, such as lithotomies The administration of anæsthetics is paid for apart, and assistants are paid from a quarter to half the amount given to the principal operator, according to the gravity of the operation In Paris there are two operating surgeons appointed and a third is nominated to act as locum tenent for either of the other two Then there are three honorary physicians who may act as consultants, and there are also five lady doctors to attend to the women employed at the post offices Further arrangements were made with the late Dr Napias Director of l'Assistance Publique, that those hospitals in Paris which have hydropathic installations should be open to the postal servants who might be in need of such treatment Then there are two dental surgeons one of either sex, appointed by the postal administration to perform extractions gratuitously, and fillings and various treatment of the teeth at a reduced tariff, which has been communicated to all the postal servants In the same manner arrangements have been made with specialists in diseases of the eye ear, nose, larynx, urinary organs, and the diseases of women, by which postal servants may obtain advice at special low rates Thus in Paris the work of the 16 postal medical officers is considerably reduced by the help of the five lady doctors who attend to most of the women employed at the post office, while the two operating surgeons the consultants the specialists, and the surgeon dentists all tend to reduce the pressure

---

[1] THE LANCET, June 22nd, 1901, p. 1794.

In England also the postal medical officer does not attend to everyone who has the right to claim his service Many postal servants are members of friendly societies, and call in the medical officer of the friendly society, who is perhaps nearer at hand or whom they may prefer personally The club medical officer's certificate is accepted at the post office and thus reduces the work but does not affect the pay The postal medical officer still receives the 8s 6d per annum though he may only have to countersign the club medical officer's certificate On the other hand, the English postal medical officer has to perform even the most serious operations without any assistance or extra pay But this again is much relieved by the hospitals where the postal servants easily gain admittance and prefer to go Nevertheless if a postal medical officer should happen to enjoy a high reputation as an operating surgeon it would go very hard with him for the postal servants would probably prefer that he should operate on them and would refuse to go to the hospital All that the postal medical officer in England can do is to charge extra for the administration of anæsthetics, for an assistant or for a consultant Also and on the plea that dressings are not medicines they can be counted as extras But these extra charges are not paid by the postal authorities, they have to be obtained from the patients themselves In France the State, and not the patient pays for operations, anæsthetics, assistants, consultant's advice &c It is only in the case of more elaborate dental operations, and certain very special diseases that the postal servant himself has to pay Even in these latter cases the Minister of Posts and Telegraphs steps in to save the postal servant from the allurements of the quack, by making a special contract on his behalf with specialists of unimpeachable reputation where he can get advice on a scale of payment that is in keeping with his means It will be seen therefore that while the French postal medical officer is expected to attend to the vast majority of the cases of sickness that arise, still ample provision has been made to meet exceptional circumstances

In England no provision whatsoever is made The medical officer gets his 8s 6d and if that does not suffice he must make whatever arrangement he can with the patient himself or with public charities, such as the hospitals, to supply the deficiency If this cannot be done then he must pay the deficiency out of his own pocket Indeed, it really does look as if it did not matter much what happens so long as the Government is not bothered by the consideration of intricate details There is such a delightful and lazy simplicity about the 8s 6d If one man will not take it the other will, and the higher authorities will then rest in peace, undisturbed by the thought that bacteriological examinations may be necessary, that hydropathic treatment may be desirable that a general practitioner cannot be expected to perform every conceivable operation and that a second opinion should be forthcoming in serious cases There is the 8s 6d if there are many postal servants in the town or district it makes a nice round sum in the course of the year, why trouble further? The medical officer will make the best of the matter and carry out the British tradition of 'muddling through somehow,' while as a nation we may congratulate ourselves that our all round standard of medical education is very high It is true that there are some postal servants who never remain a year in any district but travel from place to place repairing telegraph fitting &c The system of annual payment cannot apply to them, but then it would require a considerable effort of imagination to devise another system, and if there is one thing a governmental department dislikes it is that of having to devise something new Yet here is a totally different condition of things A certain number of postal servants only remain a few weeks sometimes only a few days in the same town Who will attend them when they fall ill? Force of habit suggests the local postal medical officer as an answer to this question But what should the postal medical officer be paid? And again force of habit suggests 8s 6d and so the matter is settled Thus if an itinerant worker contracts typhoid fever, breaks his leg or otherwise suffers seriously the postal medical officer must see him through and supply him with all the medicaments necessary for 8s 6d If the itinerant worker has a slight cold want a little liquorice the postal medical officer will supply this inexpensive and anodyne medicament and will likewise receive 8s 6d This is simple and avoids so much discussion In France if a postal servant is hurt he will receive the attendance of his usual medical officer and this officer will be paid 2 francs a visit over and above his regular salary If the hurt is very serious the operating surgeon may be sent for and the latter receives 5 francs a visit and is also paid for the operation should one be performed For an amputation £4 is paid and all assistants are also paid In England there are no such complications The medical officer gets 8s 6d and he must amputate for that sum unless he is able to escape from his responsibilities by passing the patient on to some hospital

Nevertheless and in spite of inconsistencies such as the above, the holding of an official position has many advantages and if the remuneration in some cases is absurdly inadequate there are compensations Every candidate for the postal service has to be medically examined before he is admitted and this examination was included in the 8s 6d annual allowance One of the first results of the formation of the Postal Medical Officers Association was the alteration of this very hard rule When the Duke of Norfolk was Postmaster General he allowed a fee of 5s for the medical examination of each candidate Since then this sum has been increased to 10 [illegible] for candidates desirous of joining the established staff Then when the Teachers [illegible] came into force the teachers [illegible] in England and Scotland thoug[illegible] postal medical officers were appointed to make the [illegible] examinations and were authorised to charge the candidates 10s 6d per examination In some towns this makes a good addition to the yearly income and it has an element of regularity about it for the examinations all come in April The provincial competitive examinations for various branches of the civil service inland revenue officers excise officers &c all take place in April and they also are medically examined by the postal medical officers, to whom they pay a fee of 10s 6d Then the Post Office itself pays its medical officers 5s for examining persons who insure their lives at the Post Office for small sums not exceeding £50 But if this examination of candidates brings grist to the mill it also often occasions trouble worry, and unpleasantness A candidate may go to any postal medical officer and if rejected by one he applies to another till someone does pass him This of course means a fresh fee each time when it is paid by the candidate but if he is a candidate for the postal service the process is different, for it is the Government and not the candidate who pays the fee for the examination The candidate, nevertheless has a right of appeal In that case he goes to some general practitioner who is unacquainted with the sort of work done at the Post [illegible] Under the [illegible] case, and [illegible] date may [illegible] lodge his appeal but he must at the same time deposit two guineas The postal authorities then institute an inquiry and [illegible] a medical practitioner who has been selected as referee. Perhaps this is a practitioner living in the same town as the postal medical officer who rejected the candidate. The referee knows nothing about the first opinion that was given and may by passing the candidate injure the reputation of the postal medical officer who has not done so. The latter should either be invited to attend at the second examination or at least to send some explanations. As it is, he may be condemned without a hearing, and this, too, by a rival practitioner living in the same town. In any case, in selecting a referee care should be taken that there should be no circumstance likely to throw a doubt upon his impartiality. Many representations have been made by the Postal Medical Officers' Association on this subject, but the higher authorities have not yet moved in the matter. In practice the referee generally passes the candidate, and this, of course, reflects more or less discredit on the postal medical officer who had shown himself more particular and had rejected the candidate. Therefore, when a postal medical officer has gone through this somewhat humiliating experience once or twice he concludes that it is better policy to pass the doubtful cases, and thus the interests of the service are sometimes sacrificed.

Apart from medical attendance and medicine the British postal medical officer must make constant reports as to the state of all his patients who are not well enough to be at their posts. Special reports are constantly asked for as soon as a postal servant has been away from his work for more than a fortnight. Then an annual report on all cases of illness occurring in the year has to be carefully drawn up. Each case must be classified and details given, while reference must be made to any neglect of duty, to the sanitary condition of the dwellings of the patients or of the post-office itself, and if these defects require immediate attention this must be stated. These documents should be of great interest from the statistical point of view, for they include not merely deaths but all cases of illness. Nevertheless, no use worth mentioning has been made of these valuable records. Then, again, there is the question of the proportion of men who are permanently invalided and pensioned off before they reach the age of 60 years. This also necessitates a special examination and a careful preparation of the certificate. The rule is that every man who has served 10 years and is invalided or who has reached the age of 60 years is entitled to a pension. This pension is estimated at one-sixtieth of his salary for every year of service rendered. Thus, if the salary be £60 a year the pension will be of as many pounds as there have been years of service.

In France each postal servant has a stiff cardboard *Livret Sanitaire*. This, after giving the name of the bearer, sets out a copy of the certificate of physical aptitude which was given when he applied for the post. Then there are two ruled folio pages divided into three columns. On the first is inscribed the nature of each illness, on the second its date and duration, and on the third the patient's residence. Each postal servant has this bill of health or sanitary passport, which can be readily referred to, so that when he changes his address or for some other reason comes under the care of another medical officer the latter at a glance has a notion of his new patient's past medical history. Then to facilitate the keeping of the records different coloured papers are employed. The medical officer called upon to treat a patient receives a requisition on yellow paper. If he is only to pay a visit of control then the colour of the paper is violet. For consultations at the surgery the paper used is pink. The fortnightly reports of all visits paid to patients are sent in on a form printed on white paper if these were visits of control, and on blue paper if visits for the treatment of the patients. In England the process adopted is, as might well be imagined, much more rough and ready. There is an almost total absence of any such bureaucratic control. The medical men and the patients concerned are left to contrive matters as best they can to their mutual advantage. There are, for instance, no means to prevent the patients making abusive demands except the reproaches they may receive from their medical officer. The patient is supposed to apply at the post-office for a requisition form, get it filled up and sent to the medical officer. This is very rarely done, it is much more simple to send a friend or child direct to the medical officer's house. Perhaps the medical officer would be legally justified in refusing to go in the absence of a proper summons, but it suffices that the patient is ill, and he goes at once. Sometimes these printed requisitions may be sent, not by the patient, but by the postal authorities, who may suspect a case of malingering or of alcoholism.

It is only employés whose wages are under £150 a year who are entitled to the gratuitous services of the postal medical officer. As a rule they are very considerate and never call the medical officer up at night unless it is a really urgent case. On the other hand, the medical officer is very popular, he does not cause terror like the other officials, but calls to help rather than to reprove. If an employé is ill he receives full pay for the first six months and half pay for the next six months. But within the last two years stipulations have been made that if it is a venereal disease the postal servant is not to receive any pay. Needless to remark, no such short-sighted regulation exists abroad. There it is considered more important to protect the innocent than to moralise, and therefore every facility is given to secure the immediate treatment and cure of a terrible malady that can so easily be communicated to innocent wives and children. The new British regulation may, conceivably, largely contribute to the spread of venereal disease. A postal servant cannot afford to stop work and not receive any pay. Therefore he does not consult the postal medical officer but some private practitioner or a dispensing druggist or a quack. Consequently much harm is done from want of proper care and there is a much greater danger that the disease will be spread to other and innocent persons. Again, the postal medical officer is bound to notify cases of alcoholism. But here also the postal servant escapes by obtaining, at his own expense, advice from some other medical man. This involves the delicate question as to how far the postal medical officer should be the friend and confidant of his patients, or what amounts to little short of a spy in the service of the postal authorities. Of course, it is necessary that malingering and drunkenness should be checked, yet it would greatly impair the popularity and the usefulness of the medical officer if he were to be the denunciator. It would not so much tend to prevent the evils in question, but rather it would drive the postal servant to an outside practitioner who would not report such cases and perhaps would not set the patient so rapidly on his legs again. The Post Office would benefit by the denunciations if they were made by their medical officers as stipulated in the rules, but it would lose by the increased absence of the men who resorted to other practitioners. Certainly the postal medical officer has a right of control, but if the private practitioner, whom a postal servant consults, enjoys a good reputation it will be readily understood that the postal medical officer does not like to interfere.

Comparing thus the two countries it is evident that the organisation of the postal medical service in France is more systematic and logical, but there are incidental compensations in England that are not to be despised. The payment in England is a matter of averages and of luck. In France it bears mathematical proportions to the work actually done. In France also—at least, in such towns as Paris—the postal servant has at his disposal wider medical resources and exceptional cases can be met by exceptional treatment. Again, there is this great advantage that the French medical officer prescribes and does not dispense. An official pamphlet is published explaining first that fancy pharmaceutical specialities and proprietary drugs are not to be prescribed, then there is a list of all the drugs that may be prescribed and the price at which they are to be retailed. Any dispensing druggist may sign a contract with the Government undertaking to dispense to postal servants the drugs in question at the stipulated prices. The patients have only to present the prescription to one of these. The latter sends in his account every quarter to the administration and is paid by the Government. Under the present French Government the staff of postal medical officers has been considerably increased, their districts better defined and reduced in size, and their pay augmented. Additional medical and surgical services have been created and provision has been made for postal servants who live in the suburbs outside Paris and who were for this reason not entitled to visits from the medical officers. Now the neighbouring suburbs outside the walls have been added to the nearest district inside the walls, and the medical officer of this district is to attend the patients who live near him but outside Paris. For this, however, he is to receive double pay—namely, four francs a visit instead of two francs—and the operating surgeon 10 francs instead of five francs. This new rule is dated Nov. 20th, 1900, and is a great boon to those who, from motives of health and economy, want to live outside so crowded a town as Paris. Thus it will be seen that much activity has been displayed by M Millerand in endeavouring to improve the medical services in view of benefiting both the medical men and their patients It is to be hoped that so good an example will not be lost on this country

SOME MEDICAL ASPECTS OF THE PAN-AMERICAN EXPOSITION AT BUFFALO.

(FROM OUR SPECIAL CORRESPONDENT)

IN my letter last week[1] the Munson tent, which has been adopted for use in the United States army and which is exhibited in the model brigade field hospital at the Exposition was described, and one or two other features of the display were touched upon. The tent contains all the instruments and materials necessary for the adequate performance of operations in the field These are carried in the field in surgical and sterilised chests and, as in the case of the medical chests, are packed so as to take the minimum amount of room Ligatures and sterilised dressings, inclosed in hermetically sealed packets, to be used when needed, are carried in large quantities The light for field operations is provided by a small acetylene generator which will furnish a sufficient illumination for eight hours without being recharged

As to food the model brigade field hospital is well provided, the same exactitude in packing being observed as is displayed throughout every branch of the system A mess outfit for 100 men, with cooking utensils and tent are contained in a moderate sized chest somewhat larger and of about twice the weight of that used during the Spanish American war for the mess outfit of six men Thus it will be seen that in this instance a veritable triumph of concentration has been reached, one chest taking the place of 16 of those formerly used making a reduction in weight of at least a ton in the transportation of mess materials alone The food tent which adjoins the kitchen tent, contains field rations for 200 men, and in addition two food chests are filled with light, nutritive articles of diet in concentrated form suitable for sick persons The kitchen tent which is situated next to the mess tent, is furnished with all that is needful to prepare food for 100 men at one time The portable cooking range which is a marvel of lightness and compactness contains within itself the requisite utensils for the preparation of food for this number of patients

The most essential part of the equipment of a field hospital—indeed, of the army itself—is perhaps the means of obtaining a supply of uncontaminated water The chief method in vogue in the field hospitals of the United States army to attain this object is the Waterhouse Forbes steriliser This steriliser, adopted on the recommendation of the Army Board after a number of exhaustive experiments, as the best of many water sterilisers submitted for trial, is deserving of a few remarks Its principle action, and construction are thus described by its inventors Firstly, a source of water supply, having a maintenance level below that required for causing the water to pass entirely through the apparatus [illegible] to a part of the water in th [illegible] l by gravity until ebullition [illegible] the water to rise and pass on through the remainder of the apparatus Thirdly, the transference of the heat from the hot water passing from, to the cold water passing to the point where the heat is applied An improved apparatus of this design—one of which is exhibited in the kitchen tent of the field brigade hospital at the exposition—has recently been devised by the Waterhouse Forbes Company, the weight of which, when boxed, is 80 pounds with a capacity in an ordinary way of about 30 gallons hourly Heat for this steriliser is generated by the combustion of mineral oil one quart of the latter being sufficient for five hours continuous use It is claimed for the Waterhouse Forbes steriliser that it economises fuel, that it cools water as rapidly as it boils, and that it boils without loss of the dissolved gases; and last, but not least, that it possesses conspicuous merits distinguishing it above other field sterilisers in that it is light and portable The experience of the United States army with regard to filters tallies in the main with that of the British army in South Africa and of European armies generally—namely, that an ideal, or even really serviceable, field filter has not as yet been forthcoming

Six four horse wagons are allowed for the transportation of a United States army brigade field hospital of 100 beds, with equipment of every description for the care of that number of men—a result which speaks well for the success of the efforts of the Board to solve the difficult problem set them

A New Building for the New York Laboratory of Research at Buffalo

I have taken the opportunity, while in Buffalo at the Exposition, to visit Buffalo University, and especially the New York State Laboratory, which has up to the present done its work within the walls of the Buffalo University The interesting experiments conducted under the direction of Dr Gaylord with the view to discover the cause of cancer and his publication of the results, drew the attention of scientists throughout the world to the laboratory at Buffalo, and although the outcome of these investigations has not equalled the expectations aroused by the announcement—widely and prematurely heralded by the lay journals—that the origin of cancer had at length been finally decided, yet at the same time his researches have been productive of good. It is Dr Gaylord's intention to proceed steadily along the lines which he has mapped out and when he recommences work in October he will be able to do so under more favourable conditions than heretofore have existed The rooms set apart at the Buffalo University for laboratory investigations have been long recognised as inadequate to the purpose There is however now in course of construction in the vicinity of the Buffalo University a building which will be adapted in every respect to the object of scientific research This edifice which will be ready for use in October has been erected by a family named Gratwick as a memorial of a near relative and it will when furnished cost $30 000 (£6000) It is a three storey building of ample size and having been planned and designed under the direction of the State Laboratory staff it should not fail to satisfy the requirements of its projectors.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD[1]

On the Sanitary Circumstances and Administration of the Holsworthy Urban District by Dr THEODORE THOMSON

On the General Sanitary Circumstances and Administration of the Leicester Rural District by Dr S MONCKTON COPEMAN

On the Sanitary Circumstances and Administration of the Urban District of St Helens, Isle of Wight, by Dr H TIMBRELL BULSTRODE

THESE three reports relate to comparatively small populations and their interest is in the main local and administrative As regards the little market town of Holsworthy, in North Devon Dr Thomson indicates that its sanitary advancement has in the past been greatly hindered by its inclusion in a large agricultural area under the control of a rural district council Such conditions occur frequently and it is open to argument whether in a case of this sort remedy should be found in the separation of such a district as Holsworthy—the population of which is only some 1300—from the rest of the rural district or by the exercise of central authority to compel the rural district council to do its duty At Holsworthy the first alternative which is certainly the easier has been adopted Last year a separate urban district was created and the new district council is now faced with a number of somewhat troublesome sanitary questions Here they should be helped by Dr Thomson's report which not only points to the directions in which improvement is needed but also distinguishes the practical improvements which are most urgently called for The matter of water supply clearly claims the first place Near after year Holsworthy suffers from "water-famine" owing to the local shallow wells running dry. At these times the inhabitants are entirely dependent on water, brought once or twice in the day in barrels from a spring a mile from the town. Prevention of overcrowding of dwellings upon a certain area of land is another matter which in Dr. Thomson's view needs special attention, although, as he remarks, it is singular that such crowding should have arisen, and particularly that it should have been occasioned by recent building, in a town such as Holsworthy.

---

[1] THE LANCET, Sept 14th 1901, p 749

[1] London: Eyre and Spottiswoode, Edinburgh: Oliver and Boyd; Dublin: E Ponsonby Price 2d, 4d and 2d

Somewhat similar problems arise in the rural district of Alcester, in the south of Warwickshire. This district has a population of 11,500, of which some 7000 consist of persons living under urban or *quasi*-urban conditions in the towns of Alcester, Studley, and Bidford. These places are sewered and in Alcester water-closets are general. But as the water-supply furnished by the Alcester Waterworks Company is very inadequate, provision for flushing these closets has seldom been made and the usual objectionable results have followed. At Bidford, where privy pails are in use, there is a local contract for periodical removal of their contents by a contractor, but many inhabitants who possess allotments will not avail themselves of the contractor's services and store up excremental matter near their dwellings to use when they think desirable on their allotment patches. By the exercise of a little common sense it should be possible to avoid difficulty of this sort. If allotments are outside the town it should be easy to have available there a supply of town manure for those villagers who demand it. Dr. Copeman points to the serious overcrowding which occurs in Bidford cottages every summer through the large numbers of working-class people from Birmingham who come for a brief holiday Overcrowding is also met with in Alcester, sometimes in very insanitary dwellings. The isolation hospital is too small and has insufficient staff for the needs of Alcester, to say nothing of the adjoining district of Feckenham, from which cases are also received. It is hopeful to note that since his appointment two years ago the medical officer of health, Mr B. S. Browne, has done much good work in bringing to notice various unsatisfactory conditions in his district and in suggesting practical remedies. It is quite obvious, as Dr. Copeman points out, that the remuneration of his office is far from adequate.

The urban district of St. Helens, Isle of Wight, has a population of some 4500. St. Helens proper obtains water from a series of shallow wells which are described as both unsatisfactory and unsafe. But it is intended shortly to extend to this locality the public supply of the Ryde Corporation Waterworks which at present serves a considerable part of the St Helens district. Dr. Bulstrode points to considerable slackness in this district in securing the proper cleanliness of cowsheds. Clamour for isolation hospital accommodation has recently arisen owing to a considerable outbreak of scarlet fever which took place last year. It is said that none of the large land-owners of the locality are willing to sell land to the district council for hospital purposes. This difficulty has often been met with and surmounted elsewhere.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6261 births and 4018 deaths were registered during the week ending Sept. 14th. The annual rate of mortality in these towns, which had been 21·6, 21·0, and 19·4 per 1000 in the three preceding weeks, further declined to 18·3 per 1000 last week. In London the death-rate was equal to 16·0 per 1000, while it averaged 19·7 per 1000 in the 32 large provincial towns The lowest death-rates in these towns were 11·6 in Plymouth, 13·8 in Derby, 14·5 in Cardiff, and 14·8 in Huddersfield; the highest rates were 24·5 in Sunderland, 26·4 in Salford, 27·8 in Newcastle, and 28·8 in Gateshead. The 4018 deaths in these towns last week included 971 which were referred to the principal zymotic diseases, against 1506 and 1256 in the two preceding weeks; of these, 704 resulted from diarrhœal diseases, 77 from diphtheria, 61 from "fever" (principally enteric), 45 from whooping-cough, 38 from measles, 37 from scarlet fever, and nine from small-pox. The lowest death-rates from these diseases last week were recorded in Brighton, Bristol, Swansea, and Derby; and the highest rates in Wolverhampton, Manchester, Salford, Sheffield, and Gateshead. The greatest mortality from scarlet fever occurred in Bolton; from whooping-cough in Leicester and Gateshead; from "fever" in Swansea, Nottingham, Birkenhead, Huddersfield, and Sheffield; and from diarrhœal diseases in Wolverhampton, Manchester, Salford, Preston, Sheffield, and Gateshead. The mortality from measles showed no marked excess in any of the 33 towns. The 77 deaths from diphtheria included 28 in London, nine in Sheffield, six in West Ham, four in Bristol, four in Manchester, three in Leicester, and three in Gateshead. Nine fatal cases of small-pox were registered last week in London, but not one in any other of the 33 large towns. There were 135 cases of small-pox remaining under treatment in the Metropolitan Asylums hospitals on Saturday, Sept. 14th, against 13, 41, 74, and 92 at the end of the four preceding weeks; 60 new cases were admitted during the week, against 30, 52, and 31 in the three preceding weeks. The number of scarlet-fever patients in these hospitals and in the London Fever Hospital on Saturday last was 3065, against 3040, 3008, and 2994 on the three preceding Saturdays; 457 new cases were admitted during the week, against 273, 303, and 346 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 126, 114, and 124 in the three preceding weeks, declined again last week to 116, and were 26 below the corrected average. The causes of 34, or 0·8 per cent., of the deaths in the 33 towns were not certified, either by a registered medical practitioner or by a coroner. The causes of all the deaths were duly certified in West Ham, Bradford, Leeds, Newcastle, and in 13 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Blackburn, Sheffield, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·4 and 17·8 per 1000 in the two preceding weeks, declined again to 17·5 during the week ending Sept. 14th, and was 0·8 per 1000 below the mean-rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 14·2 in Perth and 15·0 in Paisley to 19·1 in Greenock and 24·8 in Leith. The 556 deaths in these towns included 38 which were referred to diarrhœa, 12 to "fever," 10 to whooping-cough, eight to measles, three to scarlet fever, and three to diphtheria. In all. 74 deaths resulted from these principal zymotic diseases last week, against numbers decreasing from 174 to 111 in the six preceding weeks. These 74 deaths were equal to an annual rate of 2·3 per 1000, which was 2·1 per 1000 below the mean rate from the same diseases last week in the 33 large English towns. The fatal cases of diarrhœa, which had declined from 129 to 77 in the five preceding weeks, further decreased last week to 38, of which 15 occurred in Glasgow, eight in Dundee, six in Edinburgh, four in Leith, and three in Aberdeen. The deaths referred to different forms of "fever," which had been 11 and six in the two preceding weeks, rose again to 12 last week, and included eight in Glasgow and two in Dundee. The fatal cases of whooping-cough, which had been eight, 12, and 13 in the three preceding weeks, declined again last week to 10, of which three were registered in Edinburgh, three in Dundee, and two in Leith. The deaths from measles, which had been 12, 12, and eight in the three preceding weeks, were again eight last week, and included six in Glasgow. The fatal cases of scarlet fever showed a decline of two from the number in the preceding week, and included two in Glasgow, where the three deaths from diphtheria were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 62 and 60 in the two preceding weeks, rose again last week to 79, and were 9 in excess of the number in the corresponding period of last year. The causes of 17, or more than 3 per cent. of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·5, 23·5, and 20·6 per 1000 in the three preceding weeks, rose again to 22·2 per 1000 during the week ending Sept. 14th. During the past four weeks the death-rate has averaged 22·7 per 1000, the rates during the same period being 17·7 in London and 17·3 in Edinburgh. The 160 deaths of persons belonging to Dublin registered during the week under notice showed an excess of 12 over the number in the preceding week, and included 25 which were referred to the principal zymotic diseases, against 35 in each of the two preceding weeks; of these, 22 resulted from diarrhœa, two from "fever," and one from whooping-cough. These 25 deaths were equal to an annual rate of 3 5 per 1000, the zymotic death-rates during the same period being 3·1 in London and 1 6 in Edinburgh. The fatal cases of diarrhœa, which had been 32, 28, and 29 in the three preceding weeks, declined again last week to 22 The 160 deaths in Dublin last week included 43 of children under one year of age and 29 of persons aged upward of 60 years; the deaths of infants showed a decline, while those of elderly persons slightly exceeded the number in the preceding week. Eight inquest cases and five deaths from violence were registered; and 63, or nearly two-fifths, of the deaths occurred in public institutions The causes of six, or nearly 4 per cent., of the deaths in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are announced:—Staff Surgeons: J. J. Walsh to the *Brilliant* and J. P. J Coolican to the *Sans Pareil* Surgeons: W. E. Mathew to Plymouth Hospital and M. J Smith to the *Cambridge*.

The new hospital at Haslar, intended for the reception of naval patients suffering from infectious disease will probably be completed by the end of this year.

ROYAL ARMY MEDICAL CORPS

Colonel M. D. O'Connell, is ordered from India to take up duty at a home station as Principal Medical Officer on promotion.

Lieutenant-Colonel J L. Hall, Lieutenant-Colonel G H. Sylvester, Lieutenant-Colonel G E Twiss, and Lieutenant-Colonel F. A. B Daly are in charge of General Hospitals in South Africa. Major A. Baird and Captain N. Marden are coming home from South Africa

Major B. L. Mills has arrived home from South Africa

INDIA AND THE INDIAN MEDICAL SERVICES

Lieutenant-Colonel M. Blennerhassett, C M G., R.A M C, is granted the temporary rank of Colonel whilst officiating on the Administrative Medical Staff of the Army in India

Captain T. H. Delaney, 44th Gurkha Rifles, is appointed to hold Civil Medical Charge of the Naga Hills district, in addition to his military duties.

Lieutenant C. H Stratton, R.A.M.C., is to hold Civil Medical Charge of the Muttra district, in addition to his military duties, vice Major C R Bartlett, R.A M.C.

Lieutenant-Colonel D F. Barry, Civil Surgeon, Cawnpore, is to hold Visiting Medical Charge of the Fatehpur district in addition to his previous duties.

The services of Captain R Heard (Bengal) are placed permanently at the disposal of the Government of the Punjab

Captain R. Bryson will officiate in Medical Charge of the 26th Madras Infantry.

Captain H. R. Brown is appointed to the permanent Medical Charge of the 21st Madras Pioneers

Captain P. K. Chitale, having returned from China, takes over officiating Medical Charge of the 23rd Madras Light Infantry, Secunderabad, relieving Lieutenant W G Hamilton, who is on duty with the 3rd Madras Lancers there.

Dr. T. A. Starkey has handed over (1) charge of the office of District Medical Officer, Satara, to Lieutenant-Colonel C Fancourt Willis, Civil Surgeon, Satara, and (2) charge of the office of District Medical Officer, Poona, to Captain S. Evans, Assistant Civil Surgeon, Poona.

Major G. E Weston, R A.M C, who was granted privilege leave from Nusseerabad, has returned from England and resumed his duties.

Lieutenant-Colonel H J. W Barrow, R A.M C., officiates as Principal Medical Officer, Sirhind district.

SOUTH AFRICAN WAR NOTES.

Civil Surgeon Patrick Dunne died from pneumonia and heart failure at Norval's Pont on Sept 11th.

Civil Surgeons Henry Gould, Henry Ford, Thomas Edward Dobbs, and Green McWatt have been discharged from hospital to duty.

Civil Surgeons E. Turton, E B. Jones, A. Wade, R. C. Verley, W. H. Hunter, and B G. Brock have returned to England.

Civil Surgeons Dunn, Simpson, Lowe, Brew, and Collins are on their way to England.

SOUTH AFRICAN AFFAIRS

Lord Kitchener's weekly reports show that while the Boer leaders are determined on prolonging a hopeless and ruinous conflict their forces are nevertheless being slowly but surely worn down by a process of attrition. Where there is no Government with which to make peace the conquest of a country and the occupation of its capitals are not to be reckoned as tantamount to the subjection of the population and the end of all opposition There is a dogged determination on the part of the Boer leaders not to surrender. It is an inevitable but confessedly troublesome situation, especially as regards Cape Colony, where there probably exists a good deal of disaffection and where the numerous bands of Boers roving over the colony are consequently able to replenish their supplies. The distressing part of the matter is that such irregular desultory conflicts, however futile, are followed by lists of casualties from wounds and sickness. This brings us to a very interesting and instructive article from an actuarial correspondent, which appeared in the *Times* of Sept. 17th, on the South African casualties during the earlier and later stages of the war The article is a long one, but is well worth reading by all interested—and who is not?—in the subject. The differences between the first and second years of the war in respect of casualties are set forth in tabular form, and the contrast between them is a striking and highly satisfactory one The disease-rate, as may be readily imagined, was also very much lower in 1900–1901 than in 1899–1900. It should never be forgotten that the military hospitals were labouring, too, during part of 1899 1900 under the exceptional conditions described by the then commander-in-chief, Lord Roberts—namely, that all the supplies he could get through by rail were required "for the very existence of his force"—a point which seems to us to have been too much lost sight of in the controversy about the medical service in that country.

MENTIONED IN DISPATCHES

A despatch published in the *London Gazette* of Sept. 10th from Lieutenant-Colonel J Evatt D S O, commanding the Nandi punitive expedition sent from the Uganda Protectorate, contains the following:—

> Captain P B Haig Indian Medical Service, was in charge of the medical arrangements of the force It is due to his management and careful attention to the most minor complaint of the meanest native that confidence was established amongst the horde of savages employed as auxiliaries and porters in the desire to secure their well-being and that so small a proportion of wound cases terminated fatally The ready and cheerful assistance rendered by this officer, whether connected with his department or otherwise, deserves the warmest [illegible]
>
> he assistance rendered by Mr R. J.
> er to the Protectorate, who placed
> a time when there were a consider-
> ses, to attend which there was no
> equence of the regretted death in
> ld invite attention to the testimony
> he expedition on the care and skill
> with which these cases were conducted

Lieutenant-Colonel H E Brake, D S O, reporting on the military operations in the colony of the Gambia, commends Fleet Surgeon F J Lilly and Lieutenant H. Hardy, R A M C General Sir Alfred Gaselee, commanding the British Contingent, China Expeditionary Force, commends Colonel J McB Davis, I M S principal medical officer, Lieutenant H A Williams, I M S, and Major T. C McCulloch, R.A.M C

LIBELLING A MEDICAL MAN.—At the Dawlish police-court on Sept 10th a trained nurse, aged 40 years, was charged on remand with publishing libels concerning Dr Charles Newton Lovely of Dawlish, who had attended her professionally Mr Crompton prosecuted on behalf of the London and Counties Medical Protection Society. The solicitor for the defence admitted that the defendant had written about 50 anonymous letters, which were of a "low and gross" character, containing libels concerning Dr Lovely, but he maintained that she was suffering from hysteria and had hallucinations He added that Dr Lovely had cleared his character although no one in Dawlish thought it was necessary and in conclusion he asked the plaintiff to be satisfied with an undertaking to send the defendant away. Mr. Crompton stated that he could not withdraw from the case and the defendant was committed for trial, bail being allowed.

Correspondence.

"Audi alteram partem."

"WAS LUIGI CORNARO RIGHT?"

To the Editors of THE LANCET.

SIRS,—This discussion has wandered somewhat from Mr. E. H. Van Someren's original point—namely, the results of thorough insalivation of the food *in adults*, and Dr. Harry Campbell has made of it an opportunity for urging the use of other than "pappy" food *for infants*, with the object of ensuring "the proper development of the jaws and their appendages" by mastication. But surely Dr. Harry Campbell "propounds a truism with as much energy as if he were defending a paradox." He writes as if there were something quite new in the proposition that an infant's jaws and developing teeth should be exercised thoroughly by mastication, whereas, I venture to think, it would be difficult to find a practitioner among us who is not fully aware of the importance of this point—nay, more, who does not urge it upon his patients. Where is the weaned infant who is not given his crust to suck and chew or his rubber ring on which constantly to exercise his jaws?

The difference between Dr. Harry Campbell and the rest of us appears to lie in the methods which he would adopt for ensuring this functional exercise of the teeth. He would provide for it through the medium of the food on which the child is nourished, whereas the more old-fashioned and general plan is, while gradually increasing the solid matter in the infant's diet, to provide him at other times than when at his meals with various materials on which he may, and does, constantly exercise his masticatory apparatus; and it appears to me that the reasons in favour of this latter plan are too cogent to be put aside lightly. To begin with, the time occupied by an infant at his meals is so short a part of his day that it makes little difference, as far as "the proper development of the jaws" is concerned, whether he has to masticate his food strongly or not at meal time, *provided that he is exercising his jaws during the greater part of the time when he is not being fed.* A weaned child is fed, say, five times a day, and each meal will occupy from 10 to 15 minutes; this means little more than an hour in the day, whereas his chewing of crusts, rings, corals, or what not, can be carried on for many hours—in fact, the infant instinctively spends the greater part of his waking hours in this exercise and only needs to be provided with suitable materials, preferably crusts.

A far stronger reason in favour of what I may call the artificial exercise of the jaws is found in the fact that an infant, if given food that needs absolute mastication, will certainly swallow masses much too large for the digestion to deal with comfortably or profitably. Who has not seen an infant in dire danger of choking from the swallowing of a lump of crust, meat, potato, or the like? Indeed, the one precaution needful in giving him a crust to chew is to see that it is large enough and firm enough to obviate any risk of his either swallowing it whole or separating and swallowing a large piece of it. Particularly would this drawback exist in the case of foods such as meat, fish, potato, &c. I do not see how such articles of diet can be safe for a yearling child unless they are previously finely divided, which, of course, produces the pappy food to the use of which Dr. Harry Campbell objects.

Finally, the cooked food of modern civilised folk, adult as well as infant, is of so soft a nature in general that even if our baby were fed, as so many are, on "everything that *we* has" his diet would hardly necessitate an amount of masticatory exercise sufficient to ensure a full natural development of the jaws and teeth; this, I submit, is better provided for by the time-honoured crust and ring, of which an infant instinctively makes full use, and to my mind Dr. Harry Campbell has by no means established his case in favour of attempting to attain this end by means of harder and more solid food.

I am, Sirs, yours faithfully,

Bromsgrove, Sept. 2nd, 1901. CAMERON KIDD.

To the Editors of THE LANCET.

SIRS,—Dr. Harry Campbell's letter in THE LANCET of August 17th, p. 487, does indeed give food for thought. The number of children who are brought before one with ill-developed chests, weak chins, open mouths, and other concomitants of nasal or post-nasal obstruction is indeed startling, and when, as is so often the case, one diagnoses adenoids and advises operation one is met with the pertinent question, "Why are these cases so common now, we never used to hear of them?" We answer readily enough, "Oh, these cases used not to be understood, used not to be recognised; we know more about them now"; yet we are left with the uncomfortable feeling that after all they must be far more common than they used to be; that our ancestors—for instance, our Elizabethan ancestors—could not have suffered so frequently or so severely from such a disease or they would not have developed into the fine men they did, and we feel that there must be a cause somewhere. Dr. Campbell suggests one, and there seem many reasons for thinking that he must be right. May I suggest another? Anyone watching a child sucking the almost inevitable dummy rubber teat cannot but feel that he is watching the development of the prominent lips, the narrowed palate, pharynx, and nose which are so typical of the children in question and which may well be not only a consequence but also a cause of nasal obstruction and adenoids.

I do not know whether any reliable statistics are available, but my own experience as a general practitioner has certainly been that one meets with adenoids as frequently among the rich as among the poor, and had it not been for Mr. T. B. Sellors's statement to the contrary I should have brought this forward as an argument in favour of Dr. Campbell's theory. One finds post-nasal adenoids in the country as well as in the towns, in the healthiest homes of the rich, among the children of farmers, of well-to-do tradesmen, of farm labourers, and even of medical men, as well as among the children from the slums; nor does it seem to me that improved sanitation has lessened their frequency. One is tempted at times to think that this frequency points to a degeneracy of the Anglo-Saxon race, for they are obviously abnormalities, and, unless treated, very serious ones too. But for all I know they may be just as frequent among other civilised races, and before taking such a gloomy view it certainly seems reasonable to see whether there be not some other cause common to all classes to which we may fairly ascribe them, and it seems to me at any rate that this may well be the "pap-feeding" and comforter-sucking customs of the present day.

But to return to the question of food. When the teeth come it is natural that the child should want something to use them upon, something to bite, and surely it is right that he should have it. But it is difficult to know what to recommend as food. We have been but too accustomed to see the ill-effects of letting children eat just whatever their parents eat, including cheese, raw apples, &c., to say it matters not what they eat, especially in the case of children just weaned. One thing, however, I think we may feel quite certain about: if we bring up our children on artificially digested foods, as seems to be becoming more and more the custom in the present day, we cannot expect them to develop strong digestive organs, nor will they grow up into strong human animals, a point which has, if I mistake not, been abundantly proved by experiments with other animals. The question is an important one for us general practitioners, for it is upon our decisions that the habits of the race directly, or more often indirectly, depend, and we ought to have clear ideas upon the subject. It behoves us as medical men jealously to beware of any course of treatment, however captivating and however beneficial even it may seem temporarily to be, which will in the long run tend to undermine that northern hardihood which has been so characteristic of the Anglo-Saxon race, and which has enabled England to gain and to maintain her position in the world. Coddling treatment of all sorts may be necessary for very delicate children, but far too often, I fear, such delicacy is a result of coddling, not a reason for it. There has been of late years a most beneficial reaction against coddling treatment in many directions, notably among older boys and girls. The good results of this reaction are already evident, notably in the diminished susceptibility to phthisis and other diseases of the respiratory organs. May it not well be that, if we are to get a diminution of the troubles of later life connected with the digestive organs, we must go a step further back and resolutely set our faces against the coddling treatment of these same digestive organs by artificially digested food and by the too prolonged use of soft "pap-foods" in infancy. In thinking of these organs we must not forget the permanent teeth which are undergoing development during the early years of life and which seem at present to be so rapidly deteriorating.

It seems to me that the old-fashioned custom of giving a child which is cutting its teeth a hard dry crust to bite is an excellent one. It gives the child something to bite at instead of something to suck, and so develops teeth, jaws, and buccal cavities. It stimulates the flow of saliva, it would develop the very interesting reflex which Van Someren describes, and it provides the stomach and alimentary canal with small quantities of well-masticated food chiefly carbohydrate and so tends to develop their digestive functions. Provided proper care and cleanliness be used I can see no objection to it, nor can I either discover or understand why its use has been given up and the horrible dummy teat substituted for it.—I am, Sirs, yours faithfully,

H. WILLOUGHBY GARDNER.

Shrewsbury, August 27th, 1901.

To the Editors of THE LANCET.

SIRS,—It is evident that as Dr. Harry Campbell deems argument useless, he expects the iconoclastic theories advanced in his first letter[1] to carry conviction at once to the minds of the most sceptical readers. Whilst not classing myself among these I remain unconvinced by the arguments or ill-concealed display of irritation in his second letter. My anxiety for the baby's gums is as acute as before, and I still maintain that the parts in which teeth have not yet appeared cannot furnish sufficient crushing and grinding power for thorough mastication. I do not for one moment believe that the incisor teeth could fulfil this function, and as the molars do not appear *before 18 months in a healthy child it is evident that nature* intends that age as the earliest at which food requiring thorough mastication can be given with safety. Dr. Campbell mistakes the significance of the phenomena attending the commencement of dentition. The salivation, champing, and insertion of the digits in the mouth are due to the irritation and pain caused by the on-coming teeth and I regard the flow of saliva as an indication for the addition of starchy food to the diet, not as a desire to exercise functions which should not come into play till a later period.

It is not apparent to me that defective growth of the jaw is due to lack of mandibular exercise. I maintain that the infant's jaw has plenty of exercise, and as a small jaw with crowded teeth is frequently met with as the result of early rickets the use of food requiring much mastication is clearly contraindicated by the retarded dentition occurring in that disease. If Dr. Campbell's theory as to the causation of adenoids is correct how does he account for those that are frequently met with in the first few months of life and those which one authority believed to be congenital? But Dr. Campbell has not convinced himself for whilst in his first letter he insists on food which necessitates thorough mastication in his second he only advocates a fair proportion. He need not then be unnecessarily alarmed for most diets for children over a year of age prescribed by the chief authorities contain a proportion of such food. Whether this proportion is sufficiently great cannot be ascertained until Dr. Campbell's promised evidence appears and this I await with much interest.—I am, Sirs, yours faithfully,

J. B. SPEIRS.

Balham, Sept. 2nd, 1901.

"WORKHOUSE NURSING."

To the Editors of THE LANCET.

SIRS,—The fact that a deputation from the Workhouse Nursing Infirmary has been received by the President of the Local Government Board, and that its statements and suggestions have been listened to is a cause of congratulation to all who have the good of the pauper sick at heart. But unfortunately one is accustomed to the official civility which seems so deeply interested whilst all the time the case is prejudged and decided before the counsel comes into court. The country must not be satisfied with the policy of drift, the scandal which clings round the nursing of the sick pauper has been admitted on all sides and it is time that something effective was done. An intelligent nursing order has been issued in Ireland and we may take hope for the "adjacent isles." If only Mr. Long would make some similar decree from Whitehall many of the difficulties would be cleared away. I hope that the Workhouse Nursing Association will peg away until the wrongs of these silent suffering sick paupers have been righted.

I am, Sirs, yours faithfully,

C. J. WOOD.

Nurses' Hostel, Francis-street, W.C., Sept. 10th, 1901.

To the Editors of THE LANCET.

SIRS,—In the letter on the above subject in THE LANCET of Sept. 14th, p. 755, Mr. I. R. Humphreys made such a point of the amount of study which he had bestowed upon the question that one hoped that he would have advanced some plan which, if not feasible, had the merit of being new. An outsider may see most of the progress of a game but evidently an amateur does not necessarily possess the qualifications for grappling with a very difficult question. The plan of combining small unions or parishes into districts for the better treatment of the sick poor is anything but novel and has been adopted by the Local Government Board for various purposes and on many occasions. In bricks and mortar alone Mr. Humphreys's suggestion would mean the expenditure of millions and the ratepayers would have a good deal to say upon that matter whilst the difficulties of transport and the distance of the infirmary from the patients' friends are very formidable obstacles. The friends of country pauper patients have very few shillings to spend in railway fares. But the main point of which Mr. Humphreys is probably unaware is the absence of material suitable for the training of probationer nurses. The acutely sick are but rarely present in the country infirmaries whilst surgical cases are unknown and it would be a fraud upon nursing aspirants and upon the public if such institutions were to attempt to train nurses. The principal duties of a country workhouse nurse are to feed and to keep clean infirm or helpless persons and whilst admitting the desirability I question the necessity (

orm this work.

are fully discussed in

of Nurses delivered

ual meeting last year.

I wish, however, to repeat that workhouse masters and matrons by their training are quite unfitted to have control of the sick wards and so long as they are recruited from the ranks of porters and labour mistresses so long will they be incapable of wisely governing persons of a letter social position and of sympathetically ministering to the wants of the sick. The sick wards in every case should be under the sole control of the medical officer, with a responsible superintendent nurse acting under him and the only duty of the master and matron should be to carry out the orders and requisitions of these officers. They should have absolutely no control over the nursing staff. At the same time nurses who accept posts under the present conditions should remember that they are bound to obey the lawful orders of the master and matron. If the conditions are irksome the office should be resigned but disapproval of a system does not warrant disobedience nor does it condone insubordination. I think that the affairs of a certain nursing association would be more flourishing had it inculcated these principles into its one-year trained nurses instead of making spies and rebels of them whilst telling them that they were pioneers and missionaries in a great and good movement. The needed reform can and will be effected by constitutional methods. The salaries offered by boards of guardians are not likely to tempt trained nurses to remain long in their service but this is merely a question of demand and supply. The suggestion that there should be a separate and presumably lower examination standard for Poor-law nurses as a whole I emphatically reject. The larger infirmaries can and do train their nurses as thoroughly and as fully as any of the hospitals. My opinion is that with adequate salaries and proper government there would be no lack of good nurses even in our smaller infirmaries.

I am, Sirs, yours faithfully,

F. S. TOOGOOD, M.D. Lond.,

Medical Superintendent, Lewisham Infirmary, S.E.

Sept. 12th, 1901.

[1] THE LANCET, August 17th, 1901, p. 457.

"MUNICIPAL AUTHORITIES AND THE FEEDING OF INFANTS."

To the Editors of THE LANCET.

SIRS,—I notice that in your annotation on this subject in THE LANCET of August 31st, p. 608, you make no mention of the action of my friend Dr. Boobbyer, medical officer of health of Nottingham, who has caused instructions upon the feeding of infants similar in substance to those you so kindly notice to be issued through the registrars, &c. (as are my own), for, I believe, years. That you should be unaware of this surprises me less than it otherwise would have done had I not to confess that I was quite ignorant of the work of Dr. F. G. Haworth at Darwen. As a matter of fact I made use of Dr. Boobbyer's leaflet and those issued by the National Health Society and Dr. Millson, medical officer of health of Newington, in compiling my own, of which I take credit more for the arrangement than for the material. The wording I endeavoured before all things to make of the kind "understanded of the people."

I am, Sirs, yours faithfully,

Norwich. H. COOPER PATTIN.

"THE TREATMENT OF MELANCHOLIA."

To the Editors of THE LANCET.

SIRS,—I have just read the exceedingly interesting and valuable contribution on the Treatment of Melancholia by Dr. L. C. Bruce and Dr. H. de M. Alexander in THE LANCET of August 24th. I now wish to endorse and in some respects supplement their rational methods, as I believe that a very large number of cases of insanity are amenable to early treatment. In this respect asylum physicians are often placed at a great disadvantage, especially in dealing with the less obtrusive forms of insanity, as the friends and frequently the medical attendants do not recognise the gravity of such cases, and proper treatment is only very rarely adopted at an early stage of the disease. The patients are told to rouse themselves up, frequent the busy haunts of men, direct their nervous energies into fresh channels, or are sent for a holiday, but it is only very seldom that absolute rest—mental and physical—is prescribed. Even when they do eventually drift to an asylum individualism in treatment is lost sight of and recovery is unduly protracted or does not take place. It is very unfortunate that these acute mental cases which always require prompt and often energetic treatment should so frequently be placed, as it were, "between the devil and the deep sea." They are incapable of looking after themselves and do not recognise the necessity for any interference; their friends object to an asylum so long as they are manageable at home. and often the means of treatment at home are very inadequate. A considerable number of cases where there are good nursing arrangements and supervision can be as well treated at home as anywhere else, but seeing every year in consultation a large number of cases on the borderland of insanity I have often felt the want of a hospital for acute mental diseases. There is a growing necessity and one which should be recognised in every large populous centre. There was at one time such an institution in connexion with the Liverpool Royal Infirmary, which only wanted reorganising and removing to a more suitable site, but which through what I consider gross mismanagement on the part of the then infirmary staff was abolished at the time University College was founded on its site.

Dr. Bruce and Dr. Alexander say: "We believe melancholia to be a disease of disordered metabolism, and that treatment should be directed towards increasing the excretion of waste products of this metabolism through the channels of the urinary and integumentary systems, and we mechanically accomplish this end by administering to our patients an abundant fluid dietary." In my opinion there is also in all these cases, primarily or secondarily, auto-intoxication from the intestinal tract, hence I invariably prescribe some intestinal antiseptic, such as salol. I also see that the bowels are regularly cleared out with small doses of calomel, followed by saline purgatives. During the prodromal and acute stages the patients are much better in bed, they are thus kept under complete control and secure both bodily and mental rest. It is essential that they should have a fair amount of sleep and insomnia is often a very troublesome complaint in such cases. Of soporifics they have generally had a large amount and varied assortment before I see them. About the commonest and most pernicious are sulphonal and trional. I have never seen any benefit from the use of these drugs, but I have certainly known much mental depression caused by their use.

The late Sir B. W. Richardson showed that melancholia with a suicidal tendency can actually be induced by the use of mercaptan. When a soporific is necessary I prefer a mixture containing chloral, bromide, and morphia. I often prefer, especially in cases where there is any febrile movement, a wet-pack for 30 minutes at bedtime. The patient is wrapped up in a sheet wrung out of cold water from the neck to the knees and surrounded with a pair of blankets. After 30 minutes these are removed, the patient is dried with a soft towel, and allowed to sleep between blankets. I have seen this plan succeed in some bad cases where hypnotics had utterly failed to induce sleep.

In a considerable number of these cases there is dilatation of the stomach with retention of imperfectly digested products. In such cases lavage should be frequently employed, and direct antiseptics, such as iodine, benzonaphthol, carbolic acid, salicylic acid, menthol, &c., administered.

I always prescribe a liquid diet of five or six pints until the tongue is clean and there is some craving for solid food. The dietary is fairly varied and consists chiefly of milk and soda-water or barley-water in equal parts, but never undiluted milk; water, whey, mutton broth or chicken soup, malted milk, Mellin's food, Benger's food, any light milk pudding, grapes, roasted apple with cream, or a ripe pear, &c. No alcohol or any tea or coffee.

In my experience melancholia if taken early in a large number of cases is very amenable to treatment.

I am, Sirs, yours faithfully,

Liverpool, Sept. 4th, 1901. JAMES BARR.

N.B.—I think in their records of the blood-pressure Dr. Bruce and Dr. Alexander must have used Oliver's instrument which is set about 20 millimetres of mercury too high—at least, the one which I have got is, and I therefore prefer Leonard Hill and Barnard's sphygmometer for accuracy.—J. B.

"ON THE PROPHYLAXIS OF CARCINOMA."

To the Editors of THE LANCET.

SIRS,—With reference to the above article in THE LANCET of August 31st I desire to comply with Mr. Keetley's request for evidence *re* "guilt or innocence of milk, butter, or cheese in the etiology of carcinoma."

For several years it has been my lot to practise in mission hospitals in North China and there to have operated frequently on cases of carcinoma as well as to have seen many too advanced for operation. Carcinoma of the breast is common amongst the women (cases of disease of the uterus or vagina never come except for medicinal treatment in dispensary) and cases of epithelioma of the lip and penis are frequently seen amongst the men. The Northern Chinese, at least in the port of Newchwang and in cities in the interior north of that port, *never* use either milk, butter, or cheese as articles of diet, nor do these exist amongst them. There is a *very limited* importation of condensed milk only, but my own experience as well as that of my colleagues has been that even in treating cases in hospital which seemed to require milk diet it was almost impossible to get a patient to use milk even temporarily as an article of diet, so strong is the aversion of the people to its taste and use. I am, Sirs, yours faithfully,

Glasgow, Sept. 2nd, 1901. D. CRAIGIE GRAY.

"THE CELEBRATION OF ST. LUKE'S DAY."

To the Editors of THE LANCET.

SIRS,—The presence of the leading article in THE LANCET of June 29th (p. 1840) on "The Guild of St. Luke and St. Luke's Day," and the letter of Mr. H. E. Haynes in THE LANCET of August 31st (p. 615) under the above heading, indicate a desire to strengthen the links between our religion and profession by an annual Church service on or near to the anniversary of our patronal saint. The view will, I think, be welcomed by many of those of our profession belonging to the National Church and especially by that guild which has led the van in this religious observance. But it may not be amiss to point out that to carry out the suggestion in the letter referred to of holding "a service similar" to that of St. Luke's Guild annually "in every town of the kingdom" will require a considerable and efficient organisation—a central directing and coördinating body and a local body for executive work, and will necessitate the coöperation of the incumbent of each local church selected, a special preacher or sermon, and the concurrence of the churchwardens in an offertory on the occasion and in the modes of its disposal. The latter section of the work would probably be the easier, and in respect to the former it may be suggested that as St. Luke's Guild is already organised, and as one of its present purposes is the formation of local centres for the development of its objects it might be advisable to associate the proposed local celebrations of St Luke's Day with the guild as a part of its work and so save the trouble of forming an additional organisation for this one purpose.

As a member of the guild one is tempted to refer to another portion of the letter—that of the disposal of the offertories—and to suggest that the promotion of the guild's objects—for instance, furtherance of medical missions—is not unworthy to be placed side by side with those mentioned, but for the present let that pass. Suffice it to add that the views expressed are personal ones only.

I am, Sirs, yours faithfully,
FRANCIS H. WELCH, F.R.C.S. Eng.,
Brandram road, Lee. Surgeon Colonel (retired) A.M.S.

"HAY FEVER: ITS REMEDY"

To the Editors of THE LANCET

SIRS,—I think your readers interested in the question may like to know that my suggestion[1] for the employment of adrenalin in tablets has been anticipated for I learn in a communication from the manufacturers that "during the last few months a considerable number of experimental lots have been distributed," and that before long they will be on the market. I am, Sirs, yours faithfully,

Mansfield street, W., Sept 9th, 1901. LENNOX BROWNE.

FEEDING BY THE DISTAL SEGMENT DURING OPERATIONS ON THE STOMACH AND INTESTINES

To the Editors of THE LANCET

SIRS,—Within the past few weeks, while watching the performance of a gastro-jejunostomy for pyloric stenosis it occurred to me that the nutrient injection, instead of being placed in the rectum could with advantage be run into the upper jejunum through the operation opening prior to the completion of the anastomosis. This was done with excellent results. The above instance has strengthened my conviction that the distal portion of bowel in this and similar operations might be frequently employed as a route by which the patient, often half starved or collapsed could be supplied during the operation with nourishment which would stand a fair chance of being absorbed within a comparatively short time. Food introduced in this way having to traverse part of the small and all the large intestine might reasonably be expected to be digested and absorbed with greater rapidity and ease than when inserted into the rectum. This method of utilising the distal portion of intestine as a route for food might be applied to the following cases.

Perforated gastric ulcer and perforating wound of the stomach.—After the insertion and prior to the tying of the stomach sutures a tube, more or less rigid might be passed through the perforation into the stomach and from the stomach through the pylorus, the food being poured into the duodenum.

Pyloroplasty.—A tube being passed through the pyloric incision into the duodenum, after insertion of the sutures the food could be run into the bowel immediately prior to tying the last two or three sutures.

Enterectomy.—The food might be run into the lower segment of bowel prior to completing the anastomosis.

Enterostomy for gangrenous hernia.—The food might be introduced into the lower opening which might be plugged with a swab to prevent regurgitation.

In enterectomy the clamp on the upper extremity of the lower segment would prevent regurgitation of the food during the completion of the anastomosis.

In perforated gastric ulcer or perforating wound of the stomach to obviate any possibility of regurgitation, which would not improbably be prevented by the pylorus itself, the pylorus might be closed by digital pressure or a clamp during the short time necessary for tying the previously inserted stomach sutures. In the year 1901 it is hardly possible to claim any originality for this procedure, but it might be of interest if those surgeons who have employed this method of feeding would give the results of their experience. I am, Sirs, yours faithfully,

Plymouth, Sept 14th, 1901. C. HAMILTON WHITEFORD.

THE AFTER COMING HEAD, PREVENTION OF ASPHYXIA

To the Editors of THE LANCET

SIRS.—A short time ago in attending a case of breech presentation the child was in danger of asphyxia from delay in delivery of the head. It occurred to me that in such cases it would be useful to slip the end of a flexible tube into the mouth of the child. The thoracic respiratory efforts would then result in inflation of the lungs and at the same time the entry of fluid and mucus into the air passages would be minimised. A soft catheter might answer the purpose, but for convenience of sterilisation and in order to prevent the obliteration of the lumen of the tube by pressure I would suggest the addition to the obstetric bag of a soft metal tube equal in size to a No. 8 or No. 9 catheter and if desired, provided at one end for an inch or so with a rubber covering to avoid any risk of damage to the child. I see no reference in the books to the adoption of such a method, but I take the precaution to apologise in advance to the gentleman who will doubtless write next week pointing out that he described the device many years ago.

I am, Sirs, yours faithfully,
Upper Tooting, Sept. 10th, 1901. EDWIN SMITH, M.D. Lond.

*** By a coincidence Mr. G. W. Ord describes on p. 790 of this issue of THE LANCET his successful use of a catheter in these circumstances.—ED. L.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE"

To the Editors of THE LANCET

SIRS.—According to Dr. Kidd it appears that his opponents not only advocate their opinions "too strenuously," but are fighting "in a somewhat languid manner." A surprising feat. His side assert that acquired characters are transmissible. The opponents reply that the statement is incredible. They add that there are trillions of acquired characters in the world and challenge proof of the transmission of even one of them. Dr. Kidd triumphantly exclaims that they have "fallen back on the time-worn biological line of defence the non-proven doctrine of Weismann." He means that his opponents are unable to prove a negative. Will he be good enough to explain what sort of proof he would think satisfactory? Does he expect his opponents to go through these trillions of acquired characters one by one and in each separate instance prove that there is no transmission? If this is not the meaning of his demand I am sure I do not know what meaning it has. I am extremely anxious not to appear "too strenuous," but I am forced to suggest that unless disputants adhere to the common rules of logic we are not likely to derive much profit from this controversy.

Under the ordinary conditions of civilised life repressive legislation invariably results in increased drunkenness. In consequence I stated that alcoholic selection *could* not be checked. Dr. Kidd informed the readers of *Nature* that it was stated that it *ought* not to be interfered with. He now asks "Will he not allow that if it cannot be interfered with it ought not to be interfered with?" Certainly I shall not allow it. A statement of fact is not an expression of opinion. Will Dr. Kidd allow that when he says that a patient's life cannot be saved that it is equivalent to saying it ought not to be saved?

My statement that the monkey wore down the hair more than the man contained no misstatement. The monkey uses its foot as a hand and wears down the hair on it. Man does not use his foot as a hand. Did hair exist on the ungual phalanges of his foot it would not be worn down any more than it is on the terminal phalanges of most other mammals—e.g., the dog and the cat. Yet man has lost the hair and the monkey retains it. Clearly then the loss of hair is not due to wearing down. It is merely part of the general phenomena to which I drew attention. Dr. Kidd asks, "Has he not the courage of his convictions?" If a resolution to repudiate opinions which I do not hold and which are quite contrary to those I have published[1] indicates lack of courage then undoubtedly I am extremely lacking in it. However, these personal matters can be of little interest to the readers of THE LANCET. It would be better if Dr. Kidd turned his attention to the statements which originated this discussion. On the one hand, it was asserted that "temperance reform" does not reform, but the reverse; on the other hand, it was asserted that there is no evidence that parental drinking in any way affects offspring subsequently born. Both assertions remain as yet uncontroverted.

---

I am, Sirs, yours faithfully,
G. ARCHDALL REID.
Southsea, Sept. 15th, 1901.

SENDING PHTHISICAL PATIENTS TO NEW ZEALAND.

To the Editors of THE LANCET.

SIRS,—I have several times during the last 30 years made use of your columns to warn medical men against sending phthisical patients here unless they can afford to maintain themselves entirely and pay for such medicines and medical attendance as they may require. Yet they still come. Are medical men at home so absolutely destitute of all common sense that they cannot see the cruelty of sending an unhappy man with tuberculous lungs to compete in the battle of life with able-bodied men? Do they suppose that employment is any easier to obtain in New Zealand than in England? It is far more difficult. The climate—oh, the climate. As the Yankee said: "You hain't got a climate; you've weather and all sorts of samples of it, but no climate." The weather in Auckland is so capricious and changes so rapidly, often four or five times in a day, as to be most unsuitable for phthisical patients, while the houses are built without the slightest regard to hygienic rules. And within the last week I have had two new chums consulting me. My advice is, Go back as soon as you can.

I am, Sirs, yours faithfully,
R. H. BAKEWELL, M.D. St. And.
Auckland, New Zealand, August 15th, 1901.

"THE CONTAGION OF TUBERCULOSIS."

To the Editors of THE LANCET.

SIRS,—Since Professor Koch's recent pronouncement at the British Congress on Tuberculosis my mind has been much occupied with a phase of the question in dispute that seems not to have occurred to bacteriologists. It is this. If milk containing tubercle bacilli be spilled on the streets, at railway stations, in private houses, and other places that milk is often spilled in, and if this milk is allowed to dry, will not the dried tubercle bacilli from it taken into the lungs by means of the air we breathe develop tuberculosis? Bacilli that may be harmless when taken into the system by means of the stomach may be harmful when taken through the lungs. A series of investigations based on the foregoing suggestion might yield valuable results.

I am, Sirs, yours faithfully,
J. NUGENT HARRIS,
Chemist and Dairy Expert to the Agricultural Organisation Society.
Victoria-street, London, S.W., Sept. 7th, 1901.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Plague Mortality in India again rising.—Appalling Mortality in Madras.—Increase of Officers in the Indian Medical Service.—The Government of Bengal and its Plague Policy.

DURING the past fortnight there has been a considerable rise in the plague mortality. This has almost entirely occurred in the Bombay Presidency, and especially in the Dharwar district. In the week ending August 24th 3404 deaths were returned, as against 3152 for the week previous and 2618 a fortnight ago. Nearly 3000 of the total occurred in the Bombay districts and 211 in Bombay city. In Calcutta there were 22 deaths and in Bengal district 11. In the Mysore State plague is increasing, the deaths having risen from 180 to 234. In the corresponding week last year there were only 629 deaths from plague in all India. Apart from the recrudescence in certain districts the disease has almost died out. A few cases, however, continue in Sind (Karachi), in the Punjab, in certain Madras districts, and in Bengal. This lingering character at so many infected centres is not hopeful for the future, as experience shows that after a more or less definite interval the disease bursts out again.

The death-rate in Madras has been rapidly mounting up week after week. A short time ago there was a very heavy rainfall and the death-rate seems to have increased since then. For the week ending August 23rd it was no less than 119·8 per 1000 and in one division of the city actually 181·8 per 1000. The published returns do not satisfactorily explain the great mortality, because cholera is credited with only 125 deaths out of the total of 1043, fevers with 288, dysentery with 198, and diarrhœa with 44. This leaves a considerable balance for other diseases. In Bombay city also the mortality is very high, the total deaths for the week ending August 27th being 887, giving a rate of over 50 per 1000 per annum. Of the total 203 deaths are returned as due to plague. Calcutta, on the other hand, is exceptionally healthy, but it is curious to note that the mortality of the suburban areas continues as usual—i.e., about half as high again as the district of the city proper. These suburban areas are only partially drained and are not completely supplied with filtered drinking-water; otherwise the conditions of life are the same.

It is rumoured that the India Office is likely to accept the proposal of the Government of India to increase the cadre of the Indian Medical Service by 52 officers. If this be true the prospects of officers in the Indian Medical Service are likely to be considerably improved and it would render the service in many directions more attractive.

A resolution of the Bengal Government with regard to plague has just been published. It declares that there is increased evidence as to the immediate benefit from disinfection and considers that precautionary measures may be taken over a less period, but that the disinfection should, if possible, be of a more thorough character than heretofore. It admits the doubt, held by many, as to the value of the wholesale disinfection which was carried out during the autumn of 1900, but states that the quiet and patient application of disinfection accustomed the people to its use and that they consequently accepted with goodwill the rapid expansion of operations when the epidemic did arrive. It may be concluded from this resolution that disinfection of the premises where cases of plague occur is practically the only measure which will be carried out for the future. There is absolutely no reference to anything else, so that the vigorous plague policy of the early days has been resolved by various stages into the same precautions as are adopted for cholera and small-pox.

August 31st.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool Corporation Hospitals: Annual Inspection.

THE annual inspection of the corporation hospitals by the members of the Hospitals and Port Sanitary Committee took place on Sept. 10th. The party assembled at the municipal offices and under the direction of Alderman Dr. Thomas Clarke, the chairman of the committee, proceeded first to the new hospital at Fazakerley. The visitors were received by the matron and were shown over the fine and expansive estate. A feature of particular interest was the filter-beds which have been laid down for the drainage of the buildings, the process of purification being explained by Professor Boyce, bacteriologist to the Corporation, and Dr. E. W. Hope, the medical officer of health. The City Hospital North was next inspected, after which the party drove to the City Hospital East. Here very extensive building operations are going on, which when completed will afford accommodation for 130 patients. The new pavilions were objects of general approval. The Parkhill Hospital at the south end of the city was then visited After luncheon the chairman gave a brief outline of the work done by the committee He said that three years ago they acquired 120 acres of land at Fazakerley which would provide, he thought accommodation for all future extensions in connexion with the city hospital service in that district and also would enable them to cope with any epidemic of infectious disease which might arise There were at present 82 patients located in the wards—wards which for cleanliness light, and general effectiveness could not be surpassed. In Netherfield road they had a model hospital, and all must have been struck by the beauty of the estate, although the immediate surroundings were anything but ideal. At Mill-lane very extensive building operations were in progress consisting of two large pavilions, which would be equal to any in England In spite of these extensions there was still a great lack of accommodation. On that day there were 40 patients clamouring for admission, but the committee had not a single bed available. That meant leaving in their homes 40 centres of infection It was the duty of the committee to impress upon the Corporation the necessity of providing accommodation for the ordinary incidence of infectious disease By means of these hospitals they had b [illegible] was a [illegible] that [illegible] numbered 100, whilst last year the number was only 11 Small pox also had been successfully dealt with there being only 156 cases and 23 deaths last year Scarlet fever too, had been reduced to a minimum within recent years Something ought to be done to provide isolation accommodation for measles and whooping cough Last year no less than 560 deaths were due to the latter complaint whereas with regard to measles, last year 20,000 children were prevented from attending school, a state of things which might have been averted if they had proper hospital accommodation for that disease The number of beds at present available for patients is as follows City Hospital North 140, City Hospital South 88, City Hospital East, 42, Parkhill 166, Priory road 37, and Fazakerley, 82. When the present extensions now being made at Mill lane are completed that hospital will provide 130 beds, thereby bringing up the total number of beds for the whole city to 643

(FROM OUR OWN CORRESPONDENTS)

Housing of the Working Classes

THE first and the last meetings of the Trades Union Congress recently held at Swansea were connected with the question of the housing of the working classes The delegates were urged to organise agitation in order to influence sanitary authorities to put in force the powers which they now possess and a definite resolution was passed calling upon the Government to make provision for dealing with the owners of unhealthy houses to extend the time for the repayment of loans by sanitary authorities to 100 years, and to establish fair rent courts It is suggested that these courts should be composed of three members of a county council, three trades unionists, and one member of a chamber of commerce The members of the congress appeared also to be fully alive to the part which cheap and rapid transit may play in solving the housing problem, and they resolved to ask the Board of Trade to induce the railway companies to issue cheap tickets to working men and also to issue season tickets at a correspondingly cheap rate to that charged for first- and second class tickets In this connexion it is of interest to record the action which is being taken by the Glamorganshire County Council in the provision of tramways within the county Outside the county boroughs of Cardiff and Swansea even the densely populated portions of the county are very ill provided with tramways, the only systems in use at present being at Neath, Merthyr, and a short line connecting Pontypridd with the Rhondda valleys The county council propose to apply for an order under the Light Railways Act, 1896, authorising the construction of five distinct lines of a total length of about 50 miles The construction of these tramways would do a great deal towards relieving the overcrowded condition of some of those colliery districts where it is the rule rather than the exception for a five roomed house to be occupied by two families

Frome Victoria Hospital and Nurses Home

The first cottage [illegible] was established in the year 1874 [illegible] to erect as a Jubilee memorial [illegible] mmodation also for a nurses home On Sept 12th this institution was formally opened by the Hon. Mrs Duckworth The expenditure on the building has been about £5000, the whole of which sum has been already subscribed. The hospital will accommodate 14 patients in five wards, two of which contain four beds each and the remainder one two, and three beds respectively

Bristol Fever Hospital

The Bristol Corporation has finally decided to increase the accommodation at the Ham Green Fever Hospital to the extent of 62 beds at an estimated cost of £24,700

Cardiff Infirmary

Notwithstanding the special appeal made by the Mayor of Cardiff last November, by which the sum of £12,000 was raised to clear off the gradually accumulated debt of the Cardiff Infirmary, it is anticipated that the expenditure of the current year will exceed the income by more than £2000 As the total yearly expenditure is only about £9000 this deficit is a large one, and it is not very creditable to the inhabitants of a town of the size and importance of Cardiff that such a condition should be allowed to continue in the finances of this useful institution The working men of the town have never supported the infirmary to the extent that might have been expected of them In former years this has been explained on the ground that they were not sufficiently represented upon the executive committee but since the beginning of the present year the demands that were made for representation have been fully met and the strength of their representation is now proportionate to the amount of their contributions The colliers and workmen in the counties of Glamorgan and Monmouth subscribe considerable sums to the infirmary although they have local hospitals to support as well, but the Cardiff workmen during the first six months of this year only contributed to the funds of the institution £258 a quite insignificant amount when compared with the £7000 raised annually in the Birmingham workshops or with the £6000 which is annually subscribed to the support of the local infirmary by the workmen of Sunderland, a town which has a population of 20 000 persons less than that of Cardiff.

Water supplies

The continued dry weather has affected the water supplies in many parts of Wales and Monmouthshire. Even in Cardiff and Merthyr, where the storage reservoirs are rarely overtaxed steps have been taken to husband the supply. In several districts one result of the drought has been a large amount of discolouration of the water owing to the peaty character of the gathering grounds Especially has this been the case at Neath, at Pontypridd and in the Rhondda The two last-named districts obtain the greater portion of their water from the same source and for several years complaints have been made as to discolouration due it is said to insufficient filtration. Many of the inhabitants decline to drink the peaty water and obtain supplies from neighbouring mountain streams a practice which in one instance led to an outbreak of typhoid fever among the occupiers of 100 houses. In 46 houses 68 persons were attacked and only 58 recovered Notwithstanding this untoward result and the continuing danger neither the Rhondda nor the Pontypridd sanitary authorities appear at all anxious to take steps to remedy the unsatisfactory condition although attention has been drawn to it by the Local Government Board.

Brentry Inebriates Home

At the meeting of the Worcestershire County Council held on Sept. 9th it was stated that a communication had been received from the Victoria Home for Inebriates at Brentry to the effect that owing to the few male patients sent there that portion of the home was incurring a very serious financial loss, and unless the various county councils who had secured beds would consent to pay 6*d.* per bed daily, whether occupied or not, it would be necessary to close the male portion of the home. The council decided to pay the sum mentioned.

St. John Ambulance Brigade.

Mr. John S. Griffiths, L.R.C.P. Lond., M.R.C.S. Eng., the district chief superintendent of the southern and western district of the St. John Ambulance Brigade, has been appointed acting assistant commissioner by His Majesty the King, acting as Grand Prior of the Order of St. John of Jerusalem.

Sept. 16th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow University.

THE quadrangles and class-rooms of the University have during the past week been busy with the sectional meetings of the British Association. On Sept. 12th advantage was taken of the interest excited by the presence of so many distinguished scientific men to inaugurate the new anatomical department which has been erected mainly through the munificence of the late Mr. James Brown Thomson. The introductory ceremony was presided over by Lord Lister who spoke of the important position occupied by anatomy in the training of the medical student, and expressed the pleasure with which he found so well-equipped a laboratory and museum in the University where he had formerly been a professor. Principal Story, in intimating the grateful acceptance of the gift on behalf of the University, announced that Professor Cleland had presented to the new museum the whole of his extensive anatomical collection. This announcement was received with hearty applause, in acknowledging which Professor Cleland expressed the gratification which he experienced in continuing his work under the favourable conditions now established. Addresses were also delivered by the Lord Provost of Glasgow and by Sir William Turner. The new premises were afterwards inspected by the company.

Gartloch Asylum, Glasgow.

In the fourth annual report of this asylum the medical superintendent, Dr. Landel R. Oswald, states the number of admissions as 268, as against 211 in the previous year. He draws attention to the generally unfavourable type of the new cases and attributes this state of matters, at least in part, to the postponement of asylum treatment. The statistical tables show that 40 per cent. of the cases had been ill for over a year before coming to the asylum and that only 18 per cent. of these recovered. The report announces that it has been determined to erect a number of detached houses, principally for chronic cases. These are to include a sanatorium for those in whom tubercle is diagnosed or suspected, a small farm colony, homes for "doited" old men and women, and a villa for those whom it is desired to test before discharging or boarding out. The new blocks will bring the total accommodation up to 830 patients.

The British Association at Glasgow.

The papers read at the various sections which have been in session during the past week have, of course, covered a very large field. Several of them have been of special interest to the medical profession. In the section of Anthropology the President, Professor D. J. Cunningham of Dublin, gave an address on the Evolution of the Brain, dwelling more particularly upon the cerebral changes associated with the faculty of speech. Professor McKendrick, who presided over the Physiological Section, discussed the various theories of the Nature of Life. He argued that each germ contained numberless organic molecules sufficient to account for the evolution of a new being, and sufficient also to satisfy all the demands of a theory of heredity. He suggested that vital activities might be determined by motion in the molecules of living matter. This motion might be different in kind from some of the motions known to physicists, and it was conceivable that life might be the transmission to dead matter of a peculiar and special kind of motion. In the same section Sir John Burdon Sanderson read a paper on the Use of the Telephone for Investigating the Rhythmic Phenomena in Muscle. Professor Sherrington described a series of Experiments on the Brain of the Anthropoid Ape. In one of the experiments the motor area for the hand was excised, producing immediate paralysis of the hand, which was followed, however, in a few weeks' time by complete restoration of function. The brain injury led to degeneration in the course of the direct pyramidal tract which had hitherto been considered a purely human feature. A demonstration of direct clinical interest was given by Dr. Robert Kennedy of Glasgow who showed a number of lantern slides of a patient who had long suffered from Facial Spasm and in whom he had divided the facial nerve and grafted its distal end on to the spinal accessory, with the result that voluntary movements of the facial muscles had been in great part restored and the spasmodic condition had ceased. This operation was the outcome of a series of experiments in nerve-crossing. In these Dr. Kennedy observed that when the nerves supplying the flexor muscles of a limb were divided and cross-united to the nerve supplying the extensor muscles the result was that the animal gradually regained control over the flexors. Another demonstration was by Dr. James F. Gemmill who showed by the projection lantern a series of specimens illustrating the Development of the Stapes in the Human Subject. Professor Cleland also read a paper on the Evolution of the Ear in the Animal Series. In the Economical Section an elaborate paper with numerous statistical tables on the Growth and Geographical Distribution of Lunacy in Scotland was submitted by Dr. J. F. Sutherland, Deputy Commissioner in Lunacy. The sections generally have been well attended and the whole meeting has been a great success in every sense of the term.

The New Asylum near Aberdeen.

On Sept. 14th the foundation-stone of the hospital block at the new asylum at present being erected by the Aberdeen City District Lunacy Board at Kingseat, Newmachar, about 12 miles from the town, was laid by the wife of the chairman of the board.

Sept. 17th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Commission on University Education in Ireland.

THE sittings of the Royal Commission on University Education in Ireland will open on Sept. 19th at the Royal University Buildings, Dublin The proceedings will commence at 11 o'clock each day, and so far as can be ascertained the first session will last for about 10 days. Among the earlier witnesses will be the secretaries and some members of the Senate of the Royal University of Ireland.

The Main Drainage of Dublin.

In the opinion of many the most urgently required measure in connexion with the public health of Dublin is the purification of the river Liffey. It is accordingly satisfactory to note that the main drainage works which are being carried on with that object are now in active progress. The drains on each side of the river are completed, and for some time past workmen have been engaged in making excavations opposite Hawkin's-street and at Burgh Quay on the south side. At the latter point the excavation is already more than 25 feet below the level of the bed of the river, and a tunnel is now being constructed for the reception of a huge syphon which will take from the Marlborough-street side the sewage of the northern district which will be conveyed thence to the depôt at the Pigeon House. The tunnelling has been successfully executed for about 20 feet under the bed of the river from the Burgh Quay side, but it will be a long time before the stream can be crossed and a connexion made with the northern sewage works. It cannot be effected in less than another year and may require much longer. It will cost probably more than £300,000. Everything, however, goes to prove that the result will be satisfactory and that Dublin will ultimately be provided with a main drainage system as perfect as that of any city in the United Kingdom.

Proposed Sewage Scheme for Belfast.

At a joint meeting of the Public Health Improvement and Works Committees of the Council of the Borough of Belfast, eld on Sept. 10th, two very important reports—one by Dr. E. A. Letts on the scheme of sewage purification proposed for Belfast and its probable effects on the Lough, and the other by Dr. J. Lorrain Smith on a bacteriological investigation of the experimental beds for the treatment of sewage—were received and considered. It was decided after discussion to recommend the Council to put down four more experimental beds and to construct such other works as Dr. Letts, Dr. Lorrain Smith, and the borough surveyor might consider necessary. It is said that the committee were not satisfied on the information placed before them that the bacterial process would effectively purify the sewage. Both reports indicated a great deal of original work. Dr. Letts's report concluded as follows. "1. The treatment of the sewage by double contact with bacteria beds and the discharge of the resulting effluent into the Lough is, under all the circumstances, the most suitable method for the disposal of the sewage of Belfast. 2. The nuisance in Belfast Lough, or the 'foreshore nuisance,' is caused by decomposition of the green sea-weed, *Ulva latissima*, the growth of which in such enormous quantities is due mainly to the discharge of the crude sewage of the city into the Lough. 3. It is probable that with efficient purification of the sewage escaping into the Lough the sea-weed will eventually be so reduced in quantity as to cease to give rise to a nuisance" He recommends that investigations should be made as to the best material for filling the bacteria beds. Beds of "clinker" have been largely used elsewhere with satisfactory results In Belfast the coke beds are inferior to the brick beds in their purifying action. He thinks finer-grained material might be used in the lower beds with advantage and suggests that "septic tank" treatment of the sewage previously to that of the bacteria beds might be tried in view of the results attained at Manchester. As to the "foreshore nuisance" he thinks that the towns and villages situated along the Lough shores should adopt a system of purification for their sewage before it is discharged into the Lough; the discharge of distillery refuse into the Annswater river should also be discontinued. Reclamation of the moblands where the *ulva* collects and grows should be encouraged. The foreshore should also be kept clear by the proper sanitary authorities by carting the weed away. He believes that the sea-weed might be used as a further purifying agent by allowing the effluent to flow into ponds containing sea-water and the growing *ulva*, and after a suitable period of contact discharging the mixture of sea-water and effluent into the Lough in such a manner as to retain the sea-weed within the ponds. These ponds might be made tidal and [illegible] during the rising [illegible] would be free from [illegible] serve to encourage the growth of the sea-weed in the Lough itself. As the sea-weed when fresh is easily disposed of either by drying and burning or by digging into the ground (it is an excellent manure) its amount in the ponds could be kept under control without difficulty. Dr. Lorrain Smith is convinced that the committee are justified in proceeding in an experimental manner towards the establishment of a scheme of sewage purification similar in type to that exemplified in the present brick beds.

The Royal Victoria Hospital, Belfast

The Board of Management of the Royal Victoria Hospital, Belfast, at their meeting on Sept. 14th, decided to appoint a resident medical superintendent in the place of their late officer, Colonel Glancy.

The British Association.

In Glasgow, on Sept. 13th, it was decided that the meeting of the British Association next year would be held in Belfast, on Wednesday Sept. 10th and following days A very good guarantee fund has already been begun in Belfast The next president will be Professor J. Dewar, F R.S., Fullerian Professor of Chemistry of the Royal Institution, London.

Larne District Nursing Society.

At the annual meeting of this society, held on Sept 14th, it was announced that Mrs. Stewart Clarke, whose husband has already contributed £1000 to the society, would add £500 in her own name. A legacy of £250 has been left to the society by the late Mr. I. S. Howden.

Death of Lieutenant-Colonel Samuel Flood, R.A M C

The death took place on Sept. 14th, at his residence, Omagh, of Lieutenant-Colonel S Flood, L.R.C P. Edin., of the Royal Army Medical Corps. He was on leave when he became indisposed and was attended by Dr. Edward Thompson and Mr. J. J. Todd. The late Lieutenant-Colonel Flood entered the Army Medical Department in 1864, the year after he qualified, and retired on August 24th, 1887, with the honorary rank of Brigade-Surgeon. He was appointed surgeon to the Military Depôt, Omagh, on August 10th, 1889. The deceased officer had seen considerable service. He was in the Afghan War of 1878-80, for which he received the medal, the Soudan expedition, 1884-85 (Nile), and was with the river column in the action of Hirbekan (medal with two clasps and bronze star) He leaves a widow and two children. He was buried with military honours.

Hospital Saturday in Belfast.

Saturday last (Sept. 14th) was the day on which the annual collection was made for the Royal Victoria Hospital, and it is gratifying to announce that about £700 will be realised as a result, the amount for this year being the largest on record.

The Typhoid Fever Outbreak in Belfast.

I regret that there is no appreciable fall in the number of cases of typhoid fever in Belfast, the numbers notified for the last recorded three weeks being 95, 87, and 93 per week.

The Death of President McKinley.

In no portion of the United Kingdom has there been more real and more widespread sorrow at the death of the President of the United States than in Ulster. The late head of the United States was directly descended from an old north of Ireland family who settled originally at Dervock, in North Antrim The old house, built in 1765 (apparently, from the initials and date "W. McK., 1765," cut on a stone) by a William McKinley, is still in existence, and is a place to which Americans, when staying at Coleraine or Portrush, often make pilgrimages; but there is evidence that further back than this the McKinleys lived on the same spot—it may have been in a ruder dwelling torn down to make room for the present house Considerable surprise is felt here in medical circles that such an optimistic view was taken by his attendants of Mr. McKinley's condition. Several days before the unfortunate issue a letter appeared in one of the Belfast papers, signed "M D. since 1864," in which the writer warned the public to "rejoice tremblingly." The importance in gunshot or revolver wounds of the abdomen of not "holloing until you are out of the wood" is very obvious. No one suggests that our American *confrères* did not do their very best in the case, but it might have been advisable to be more reticent. The multiplication of medical attendants—leading as it does to newspaper interviews—often gives rise to apparently contradictory statements.

Sept 17th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Child Killed by Lice.

THIS misfortune has actually come to pass at Toulouse. A little girl, aged three years, was brought to the hospital where her mother lay dying owing to acute phthiriasis The poor child was covered with wounds, her hair was full of nits, there was acute conjunctivitis, and the eyelids were glued together with secretion The chest and arms were covered with crusts of impetigo and long cicatricial tracks, while a great part of the back and the thighs were covered with large patches of superficial erosion. Diarrhœa was profuse, the temperature was 37·8° C., and there was acute thirst No urine could be collected, for the child passed everything under her, and despite every care the poor child died during the night The post-mortem examination showed old broncho-pneumonia and pyæmic abscesses in the liver. Dr Laurent, under whose care the child was, remarked that the cause of death was similar to that following extensive burns, being due to the skin lesions which, primarily set up by lice, led to acute infection from the skin.

An Action for Damages owing to Injury caused by Cocaine

The daily press has been greatly concerned at the case of a woman who died in the Beaujon Hospital after an operation on her foot, anæsthesia being brought about by intraspinal injection of cocaine Legal proceedings are to be taken. The facts are as follows. On August 2nd Madame

B—— was brought to the hospital suffering from a wound in the ankle caused by a fall from a wooden horse. She was apparently well and the wound was not serious. But two days later the temperature rose and on August 6th the surgeon in charge, not being satisfied with the progress of the case, gave the patient an injection of cocaine, opened up the wound, carefully disinfected it and applied a dressing. On August 7th, the effects of the cocaine having entirely gone off, Madame B—— died. Her death is attributed to a profound infection from the wound, and apparently the cocaine had nothing to do with the unfortunate result.

Illegal Practice of Medicine by a Foreign Medical Man.

A case is now before the courts in which the director of a medical institute at Paris is being prosecuted for illegal practice. The director, Monsieur S——, in answer to the examining magistrate, said that he was a doctor of a German faculty and that he never practised medicine in France without the assistance of a French doctor—namely, Dr. C——. Despite this explanation the case was referred to the next court. By the law of Nov. 30th, 1892, no one has a right to practise in France with a foreign diploma unless it is endorsed by a French faculty, and this endorsement did not exist in the case of Monsieur S——. The examining magistrate has summoned some of the defendant's patients in order to find out whether they were really treated by Dr. C——, as Monsieur S—— alleges, or by the latter alone.

A New Crematorium.

The Prefecture of Police has just received an application concerning the erection of a crematorium for incinerating corpses and bodies of animals which have been used as subjects at the School of Medicine. M. Charles Richet, the elaborator of the idea, relies upon two chief arguments. First comes that of expense. The cost of removal of fragments from the dissecting-rooms and of the bodies of animals which have been used for experimental purposes in the laboratories amounts to some hundreds of francs a quarter. Secondly come hygienic reasons. The carriage of these fragments, which, to say the least, are not in the best condition, is not without danger to those persons who meet the vehicle on the way to the burying-ground. It would be far safer to burn the remains and the expense of a permanent crematorium would not be great. Experiments already made in the laboratories with a portable stove have given excellent results. The Faculty of Medicine is strongly supporting M. Richet's proposal, but the inhabitants in the neighbourhood of the School of Medicine are afraid that the smell of the burning débris will cause a nuisance. However, it is most probable that the proposition of M. Richet will be adopted after the scheme has been gone into.

The Return of the Red Cross Ambulance from China.

The French Society for Aid to the Wounded sent out to China at its own expense an ambulance intended to serve as an auxiliary to the official hospital establishment. Its staff consisted of three naval medical officers lent by the Admiralty and one civil medical man, two resident medical officers from the Paris Hospital, an apothecary, ten naval orderlies, two civil nurses, and five sisters of charity, together with three members of the society. The administrative head was a man of great devotion and energy, a Monsieur De Valence, who underwent the sad affliction of losing his wife and daughter in the terrible fire at the Charity Bazaar. Many times he might be seen, despite his 65 years and the intense cold, assuring himself by a personal inspection that the soldiers should want for nothing. Both the material and the staff of the ambulance disembarked at Nagasaki, where they settled themselves in the buildings of a school kept by some English sisters, who sent their pupils away to make room and acted themselves as nurses. The ambulance was well provided with everything necessary, the great commercial French houses having freely given such things as provisions, mattresses, blankets, flannel jackets, and bottles of champagne. The ambulance was the only one which was set up on land among all those organised by the various European nations. Its chief function was to act as an evacuation hospital by collecting the sick who filled up the ambulances in the fighting line or who fell ill on board the ships which were taking them home. During the seven and a half months in which it was in action it treated 415 patients. These were mainly cases of dysentery occurring among the troops from Indo-China which were sent to the relief of the Legations, but there were also many cases of pulmonary disease and of typhoid fever. No actual wounded were received except upon two occasions—viz., after the attack upon Tientsin, where there were a great many wounded, and after the unfortunate affair at Chan-Hai-Kouan, where, in the darkness, the Russian and French troops fired upon one another. At this time the hospital took in eight wounded, of whom three died and one underwent amputation. The general sanitary condition of the hospital was excellent throughout, and the mortality was lower than that which is normal to the French army in times of peace, despite the intense cold which often reached 20° or 23° below zero centigrade. All the water drunk was distilled.

Sept. 17th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis and Perlsucht.

IN the *Berliner Klinische Wochenschrift* Professor Baumgarten of Tübingen discusses the communicability of tuberculosis from animals to man. Professor Koch in his address delivered before the London Congress had rightly observed that this question could only be solved by experiments which were, of course, impracticable. Professor Baumgarten in his communication states that inoculation of the human subject with bovine tuberculosis was performed 20 years ago, not for experimental but for curative purposes. Professor Rokitansky had at that time announced that cancer and tuberculosis were never present together in the same individual and that the two diseases were antagonistic to each other. Though this view has now been proved to be erroneous, for cancer and tuberculosis are not so seldom found to be present in the same subject, a surgeon whose name is not mentioned has tried whether by injections of tubercle bacilli malignant growths might be made to disappear. Cultures made from erysipelas have also been injected into the human subject with a like object. The injections of tubercle bacilli had no effect whatever on the disease and did no harm to the patients. Professor Baumgarten then mentions that when the surgeon happened to have no cultures of the bacilli of human tubercle at his disposal he used cultures of perlsucht bacilli obtained from the ox, but although injections of these bacilli were given to more than six patients tuberculosis did not develop in any of them: Sometimes a slight suppuration appeared at the site of the injections, but after the patients eventually died from cancer no symptom of tuberculosis could be discovered at the necropsy; no tubercle bacilli were present either in the lymphatic glands of the part or in the internal organs, or in the malignant growths. Inoculations of the human subject with highly virulent cultures of perlsucht thus proved to be as negative in their results as are injections of human tuberculosis into cattle. It is interesting to learn that the former fact was ascertained 20 years earlier than the latter, which was only made known by the recent researches of Professor Koch and Professor Baumgarten. Both of these gentlemen are in accordance as to the impossibility of communicating bovine tuberculosis to the human subject or human tuberculosis to cattle, but they hold divergent views as to the identity of the bacilli. According to Professor Koch's opinion the bacillus of tuberculosis is quite different from that of perlsucht; Professor Baumgarten believes that they are identical but that their pathogenic action becomes transformed when they are conveyed from man to the lower animals and *vice versâ*. He mentions some examples of this "transformation." For instance, the bacillus of perlsucht when cultivated in rabbits becomes in course of time more virulent for rabbits, whilst the same bacillus cultivated in fowls loses its virulence for rabbits. Tubercle bacilli developed in birds by natural infection are at first no more than slightly virulent for rabbits, but by successive cultures they accommodate themselves to the medium presented by the new host and eventually become highly virulent for rabbits. From these facts Professor Baumgarten concludes that the bacillus of tuberculosis when cultivated for innumerable generations in either cattle on the one hand or human beings on the other becomes so modified that it is no longer able to grow when transplanted from cattle to the human subject and *vice versâ*.

Dr. Garnault in Berlin.

Dr. Garnault, the French medical man who is reported by your Paris correspondent[1] to have offered himself to Professor Koch for experiments on the identity of human tuberculosis and perlsucht, has arrived at Berlin He had a long interview with Professor Koch, the language used being English, as Professor Koch does not speak French, neither does Dr Garnault speak German Professor Koch declined to give injections to Dr Garnault, and advised him, if he really wished to do something towards the elucidation of the question, to drink unsterilised milk from a tuberculous cow for about a year and to abstain as much as possible from other foods Dr Garnault agreed to do so, but, in addition, *will have an injection of highly virulent perlsucht bacilli* performed every month

A Successor to the late General Staff Surgeon Dr von Coler

General Staff Surgeon Dr von Coler, the head of the Army Medical Corps, died in Berlin on August 26th as you announced at the time His death was not generally expected, for only a few persons were aware that his health had failed very much during the last few months, and he continued at his post until some weeks ago, when he was attacked with severe pain in the stomach and liver The fatal issue was due to a malignant growth Dr von Coler's work has been described in THE LANCET of March 30th, 1901, p 975 on the occasion of the celebration of his seventieth birthday It was due to him that the army medical corps attained its *present high standard*, as he wished *the army medical* officers to be not only officers but thoroughly trained medical men, and he made arrangements by which his subordinates always had ample opportunities of keeping abreast with the progress of medical science He will not be an easy man to follow by any means The name of his successor is not yet known but some daily papers report that Surgeon General Leuthold, the principal physician in ordinary to the Emperor, will become general staff surgeon and head of the Army Medical Corps

(FROM OUR OWN CORRESPONDENT)

Hospital News

THE annual meeting of the subscribers to the Melbourne Hospital was held recently The financial statement presented showed that for maintenance the treasurer had received during the year the following amounts Government grant (fourth instalment for 1899 1900), £3000 , Government grant for 1900-1901, £12 000 , grants from municipalities £375 7*s* , private contributions, £3462 3*s* , Help the Hospital Fund (per the *Argus*), second instalment, £7511 12*s* Hospital Sunday Fund £1339 14*s* 9*d* , proceeds of entertainments, £413 16*s* 9*d* , proceeds of the Melbourne Hospital Bazaar, £8769 6*s* 3*d* , in patients' contributions, £1699 , out-patients' contributions, £1216 4*s* 4*d* , visitors fees £291 4*s* 6*d* , medical students' fees, £465 , nurses premiums, £200 , interest £1509 5*s* 9*d* , sale of refuse &c £159 10*s* , sundries, £263 5*s* 3*d*, making a total of £42,675 9*s* 7*d* *The expenditure for maintenance had* been £25 488 2*s* 3½*d* , and the deduction from the receipts of this amount and of the sums due for accounts unpaid on June 30th left a credit balance of £527 3*s* 6½*d* The endowment fund had benefited by bequests to the amount of £1373 16*s* 10*d* , and the sum now bearing interest was £29 523 6*s* 8*d* The number of patients who had received treatment during the year was 21,772, and of these 5082 were admitted into the wards and 16,690 were treated in the out patients' department The number of in patients discharged either cured or relieved was 3928 and 123 had for various reasons been discharged. Owing to the insufficiency of accommodation *surgical patients had frequently to wait a considerable* time before being admitted, and, moreover, the inadequacy in the number of surgical wards rendered it difficult to provide a reasonable amount of surgical training for nursing probationers The committee hoped to remedy this condition of things at an early date by utilising as a surgical ward a portion of the hospital which had until recently been used for other purposes A further improvement that was most urgently needed was the erection of a suitable building for the reception of patients suffering from infectious diseases The Melbourne Hospital was the only institution in the metropolitan area that treated infectious diseases and, in addition to the large number of adult cases of this nature that demanded admission, all the children of the poor from Melbourne and the surrounding suburbs who suffered, from measles scarlet fever, and diphtheria, must, since they were received nowhere else, be admitted there The committee hoped to be in a *position during the coming year to* replace the present inadequate and unsuitable infectious diseases tents by sanitary and commodious wards —The *report presented to the thirty fourth annual meeting of* the subscribers to the Victorian Eye and Ear Hospital stated that during the year 827 in patients and 5418 out patients had been treated, being an increase of 181 in patients and 111 out patients over the numbers in the previous year The number of attendances of out-patients was 28 791, and of operations performed 1478 "These ever increasing numbers,' the report continued, "have made the present accommodation in the out patient department wholly inadequate, and its enlargement has become a very urgent necessity, but the want of ground room and funds prevents this being carried out ' The receipts amounted to £3521 17*s* 9*d* , the expenditure to £3471 4*s* and there was a bank credit balance of £3674 10*s* 6*d* The building fund was in credit £375 This sum would serve as part of a reserve fund to meet the expenses which would be incurred through sewerage connexions which were estimated to cost some £500 or £600 A special general meeting was then held, when a by law was amended to allow of the addition to the present medical staff of two honorary assistant surgeons, one honorary medical skiagraphist, one honorary pathologist one honorary anæsthetist, and one honorary dermatologist —At the monthly meeting of the Board of Directors of the Sydney Hospital plans and specifications for the rebuilding of the operating theatre were considered and separate tenders were accepted for the building and for the ventilating, heating and sterilising plants —A new ward for women has been opened at Mooroopna Hospital (Victoria) by Lady Madden A memorial stone was placed in position by Mr J V Heily the oldest honorary surgeon connected with the hospital The new ward, which cost £2375 is considered to be exceptionally fine and up to-date in its construction and appointments —The method of electing the honorary staff at the Women's Hospital, Melbourne has been severely criticised from time to time and recently the committee framed new by laws abolishing voting by proxy and by minors and only allowing votes to adult life governors and to subscribers for three consecutive years These by laws were submitted to a meeting of subscribers who appointed a sub-committee to report on them The sub committee took legal opinion as to the legality of the new by laws and reported to another general meeting of the subscribers that the greater number of them were *ultra vires* The meeting referred the new by laws back to the committee of management for revision The sub committee also submitted five different proposals for the election of the staff for an expression of opinion by the meeting, and eventually it was decided that the elections should be as they always had been—that is to say, that it will be possible as heretofore for a candidate who has sufficient money *to buy a position on the staff by* creating "faggot" votes —The annual meeting of the Hospital Saturday Fund of New South Wales was held on July 30th the Mayor of Sydney (Sir J Graham M D Edin.) presiding The chairman stated that since its inauguration the fund had made steady progress Since its establishment in 1894 £29 341 had been collected , last year £4200 were collected, as against £1800 in 1894

Lunacy in New South Wales

The report of the Inspector General of Insane in New South Wales for 1900 shows that the number of insane persons under official cognisance was 4396 as compared with 4217 at the end of 1899 *These figures show an increase* of 179 The average annual increase for the past 20 years was 115 The proportion of insane to the general population was one to 309 persons in the State The number of admissions during the year was 859 Of these 730 were admitted for the first time and 129 had been in the same hospital on some previous occasion The number of admissions continues to grow as the population grows, but the last two years have shown a somewhat quicker rise than the increase in the population would have led one to expect

---

[1] THE LANCET, August 31st 1901, p 622

Of the admissions, natives of New South Wales formed 46½ per cent. ; natives of England 21 per cent., of Ireland 11½ per cent., of other Australian States 11 per cent., of other countries 6½ per cent., and of Scotland 4 per cent. The number of patients discharged recovered was 334, equal to a rate of 38·88 per cent. on the admissions and re-admissions. The percentage is under the average, but this, it is pointed out, is probably due to the retention on leave of a number of patients who in the ordinary course of events would have been discharged recovered. The number of patients discharged on probation or granted leave of absence to the care of friends during the year was 260, making those remaining from the previous year 376. The deaths numbered 276, 197 being those of men and 79 of women. Calculated on the average number resident, this gives a percentage of 6·61, which is about the average for the past 10 years. 50 patients escaped ; all but five were recaptured, and of the five none were of the dangerous class. The necessity for providing accommodation for the gradual increase in the number of insane patients under care is again brought into prominence. It is not, the report says, that there is any abnormal or unusual predominance of insanity or that insanity itself is markedly on the increase in the State, but that an increasing population necessarily involves a proportionate increase in the cases of mental diseases, as it does in those of bodily illness. With the progress of the State, therefore, an annual addition must be made to the existing hospitals to allow of these additional cases of insanity being properly cared for. The receipts of the department amounted to £17,839 5*s.* 6*d.*, and the total expenditure to £121,452 1*s.* 2*d.*

Trained Nurses' Associations.

The annual meeting of the Australasian Trained Nurses' Association was held on July 5th, Dr. F. Norton Manning being in the chair. The report stated that correspondence had been carried on with Victoria, Queensland, South Australia, and Tasmania with regard to the formation of branches in these States, but that no definite arrangement had been arrived at. Rules for a midwifery branch were agreed to at the last annual meeting, and 59 nurses had been registered under them. A benevolent fund had been initiated and had a credit balance of £70. The general finances were satisfactory, showing a credit balance of £352. The register contained the names of 414 nurses and 63 medical men.—A trained nurses' association has just been inaugurated in Victoria at a meeting of representative nurses held at the Melbourne Hospital. Its objects are to establish registration of nurses and a uniform system of training and examination, and in time to establish a benevolent fund. Dr. J. W. Springthorpe was elected president and Dr. W. A. Wood and Miss Glover were appointed honorary secretaries.

Charge against a Medical Man.

An inquest has been held in Sydney on the exhumed body of a woman named Ritchie whose husband made a charge against Dr. F. W. Marshall of Sydney of performing on her an illegal operation which caused her death. The medical evidence showed that death was due to hæmorrhage after delivery, but there was nothing to show how delivery was brought about. The woman's daughter swore that Dr. Marshall had used instruments on her mother to bring on abortion, and she also swore that she had been treated by Dr. Marshall similarly. Dr Marshall denied the statement and said that the husband had simply tried to blackmail him. The jury disagreed. As intimated in a previous communication, another charge of a similar character is pending against Dr. Marshall.

August 12th.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

Life Assurance in New Zealand.

AMONGST the questions recently discussed at the Medical Conference held in Wanganui only a few related to other than strictly medical topics. The discussion on Life Assurance was one of the exceptions, and the pertinent observations made by many of the speakers were of public as well as professional interest. The relative position of medical referees and canvassers would appear to be a very incongruous one, inasmuch as the canvasser, wherever there are several referees, has virtually the power of selecting which of them shall examine a proponent. The insurance agent or canvasser is remunerated in the majority of cases by commission, and that commission is only paid in those cases in which the proposal is accepted by the insurance company. It is to the direct advantage of the canvasser that every proposal made through his agency shall be accepted as a first-class life, and hence he naturally puts all the work he can into the hands of the medical referee who is most likely to pass a bad or indifferent life. The careful, conscientious examiner is virtually boycotted ; after he has refused to pass one or two proponents he speedily realises that his office as a medical referee is a sinecure. Can it be to the interest of any company to pursue a system which actually penalises the most conscientious and reliable referees and allows the canvasser at his own discretion to select the examiner who is in his opinion the most easily satisfied? The medical referee acts on behalf of the insurance company ; it is clearly his duty to protect his employers from fraud and to safeguard their interests. If he does his duty the canvasser has it in his power to deprive him of any opportunity of performing it. The interest of the canvasser is that all proposals should be accepted ; the interest of the company is that all bad or doubtful lives should be refused. The actual result of this conflict of interest is that the ablest medical examiners obtain the least amount of work. The remedy would seem to be the appointment of a single referee for a clearly defined district and that each referee should examine every proponent in his own district and none outside it. No canvasser ought to be given power to pick and choose who shall make the medical examination. Another point touched upon was the advisability of all reports being sent direct to the medical adviser of the board of directors. These reports are supposed to be confidential and privileged ; the would-be insurer has to make a personal statement, which covers not only his own life-history and habits, but also gives details of any diseases from which any of his relatives may have suffered, and there ought to be no possibility of such a report lying upon an office table perchance to be perused by the office boy. The confidential medical report should be submitted only to the medical adviser of the board on whom devolves the ultimate responsibility of acceptance or rejection of the proposal. It was the opinion of a large majority of the medical men attending the conference that many excellent lives were rejected on insufficient grounds, and that too little confidence was reposed in the recommendation of the local referee. Unless the local referee is incompetent his opinion should not be lightly disregarded, for he alone has had the opportunity of thoroughly overhauling the proponent and of weighing the *pros* and *cons* which render him eligible or ineligible. Adverse comments were made on the unnecessarily elaborate and voluminous forms adopted by the majority of insurance companies. Many of the questions which must be answered, both by the proponent and the medical referee, are trivial and vexatious, and appear to have been framed on the assumption that the examiner would overlook many important points unless reminded of them in black and white.

The clerical labour involved is considerable. There are persons who come to be examined who are obviously ineligible ; a mere glance will reveal the fact to the experienced examiner, or he may have personal knowledge that the proponent is suffering from a serious disease ; nevertheless, the whole tedious performance must be gone through although it is a foregone conclusion that he will be rejected. If a man or woman has a diseased heart it is quite needless to examine carefully every other organ of the body, but it has to be done. The main points on which the verdict of the conference was practically unanimous were : (1) that the canvasser or insurance agent should have no voice whatever in the selection of the medical referee ; (2) that all medical reports should be sent direct to the head office ; (3) that greater confidence should be reposed in the opinion of the local referee, who should be the sole examiner for a limited district ; and (4) that the forms to be filled up should be simplified, and that questions which seem to imply that the referee is either dishonest or incompetent should be eliminated.

Wanganui, July 25th.

Obituary.

ALFRED EDWARD AUST LAWRENCE, M.D., C.M. ABERD.,

CONSULTING PHYSICIAN ACCOUCHEUR TO THE BRISTOL GENERAL HOSPITAL.

DR. A. E. AUST LAWRENCE, as was announced in THE LANCET of Sept. 7th, died suddenly from syncope on August 29th at Bishopsteignton, Devon, where he was on a visit. The deceased received his medical education at the Bristol Medical School, where he gained several prizes and scholarships, and also at Aberdeen University. He graduated M.B. and C.M. of Aberdeen in 1872 and two years later was admitted to the M.D. He then commenced practice in Clifton and was shortly afterwards appointed physician accoucheur to the Bristol General Hospital. Upon resigning this post, which he held for many years, he was made consulting physician accoucheur to the institution. Dr. Lawrence had been for several years professor of midwifery and diseases of women at University College, Bristol, and he held the appointment at the time of his death. The deceased was well known throughout the West of England as an authority on diseases of women and had a [illegible] He was a former president of the [illegible] Society and also a vice-president of [illegible] London, being a member of the council of the latter society for several years. He was the president-elect of the Bath and Bristol Branch of the British Medical Association. Dr. Lawrence was only 53 years of age at the time of his death and has left a widow and two daughters for whom much sympathy is felt. The deceased will be greatly missed in Bristol and Clifton, not only by his patients and friends, but by his many professional *confrères* who so often availed themselves of his valued opinion. The funeral, which took place at *Redland Green, Bristol*, on Sept. 3rd, was numerously attended.

HENRY WILLIAM LIVETT, M.R.C.S. ENG., L.S.A., L.R.C.P. EDIN.

MR. HENRY WILLIAM LIVETT died at his residence in Wells, Somerset, on August 28th, being the anniversary of his eighty-seventh birthday. He received his medical education at St. Bartholomew's Hospital and at Paris; he became qualified as M.R.C.S. Eng. and L.S.A. in 1837, taking the qualification of L.R.C.P. Edin. in 1859. Mr. Livett had been in practice for many years in Wells, being formerly medical officer of health of the borough and surgeon to the dispensary. He was a prominent member of the town council and filled the office of mayor on two occasions; while holding that position he presented the corporation with a silver-gilt mayor's chain and a silver loving cup which he himself had ornamented. Mr. Livett was one of the founders of the volunteer movement in Wells and was ultimately appointed surgeon to the company. He had been a Freemason for 60 years and was also president of various organisations, educational and musical, having been up to the time of his death a remarkably busy and active citizen. At the meeting of the Wells Town Council held on Sept. 2nd the mayor proposed a vote of condolence with the family of the deceased which was unanimously passed. The funeral took place on Sept. 3rd.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The death of the following eminent foreign medical man is announced:—Dr. Alfred Vaucher, formerly Professor of Midwifery in Geneva.

FOREIGN UNIVERSITY INTELLIGENCE.—*Brooklyn (Long Island College)*: Dr. W. F. Campbell has been appointed Professor of Anatomy.—*Brussels*: Dr. Rommelaere is resigning his Professorship of Clinical Medicine, Professor Stiénon taking his place.—*Leyden*: Dr. J. Korteweg has been appointed Professor of Clinical Surgery.—*Naples*: Dr E. Crisafulli and Dr. G. Libertini have been recognised as *privat-docenten* of Psychiatry.—*Pavia*: Dr. Mauro Jatta has been recognised as *privat-docent* of General Pathology and Dr. Mario Truffi as *privat-docent* of Dermatology.—*Rostock*: Dr. Greeff has declined the Chair of Ophthalmology

Medical News.

THE SANITARY INSTITUTE.—A donation of £100 has been promised by the Leeds Fireclay Company to the fund for the new building and endowment fund of the Parkes Museum.

WATER-SUPPLY OF TEIGNMOUTH.—The Teignmouth (Devon) District Council have unanimously adopted the recommendation of the water committee to obtain water from the Hyner Valley, near Dartmoor, at an estimated cost of about £75,000.

DEATH OF A CENTENARIAN.—Mrs. Strachan, *formerly of South Haddo, Fyvie, who died at Scatterty*, King Edward, Aberdeenshire, on Sept. 7th, had attained her 105th year, having been born at Sauchentree, Methlick, in August, 1796. Her maiden name was Martha Calder. Her husband, Mr. Alexander Strachan, farmer, South Haddo, died more than 60 years ago. For the last few years she has resided with her grandchildren.

DEATH FROM UMBILICAL HÆMORRHAGE.—The coroner for West Cornwall held an adjourned inquest on Sept. 9th relative to the death of an infant who died nine hours after birth while in bed with the mother. A previous inquiry had been held two days before, when the father and the midwife who had attended the mother of the child had stated that they could not suggest any cause of death. The coroner consequently ordered a post-mortem examination to be made and this showed death to be due to umbilical hæmorrhage owing to neglect at birth. Evidence also showed that the midwife, when fetched after the child's death, urged the friends to keep the matter quiet. The father eventually admitted that the dead child's clothes were saturated with blood when he first saw it. The jury returned a verdict of "Death from accidental hæmorrhage" and severely censured the father and the midwife for suppressing at the first inquiry all the evidence in reference to the condition of the child's clothes which pointed to the cause of death.

THE STYAL COTTAGE HOMES.—The guardians of the Chorlton Union must be pleased at the report made by the Poor-law inspectors on the homes at Styal. At the meeting of the board held recently it was stated that Mr Moorsom, inspector of Poor-law schools, had complimented the guardians on the condition of the children at the homes. He had specially asked Mr. Fuller, medical inspector of the Local Government Board, to come down to see the children, who corroborated him in stating that from a health point of view they were the best he had come across in any Poor-law institution in England. He considered that their vigour, vitality, and strength were altogether above the average. Dr. Rhodes said that no one *could visit the homes without* feeling satisfied that it was wise to remove the children to them. They were meant for those who had none to care for them, "and they should have an inspector like Miss Zannetti to thoroughly inquire, in the interests of the ratepayers, as to the children who were sent there." This lady has now accepted that duty.

THE BLACKBURN PAUPER CHILDREN.—At a recent meeting of the Blackburn Board of Guardians Mr. Jenner-Fust "ventured respectfully to differ from the board as to the management of pauper children." They had scattered cottage homes and it seemed to him that the object was to do away with the connexion between children and adult paupers, which advantage was lost if the former were first received at the workhouse. But the children were retained at the workhouse till they were five years old. This he considered to be a very great drawback to their probable success afterwards. "They got very little, if any, education at the workhouse," and when they went to the public elementary schools *they were put into competition* with those who had been at school for a year or more and were handicapped to that extent. He might have added that impressions received at that age are apt to be permanent, and that the taint of pauperism, the stigma of low caste, will in many cases be firmly fixed and be a disadvantage to them in their course through life.

Literary Intelligence.—During the present month Messrs. Baillière, Tindall, and Cox have published the following new works: "Diseases of the Stomach and their Surgical Treatment," by Professor A. W. Mayo Robson, F.R.C.S., and B. G. A. Moynihan, F.R.C.S.; "Syphilis and other Venereal Diseases," by H. de Méric, M.R.C.S.; "Lessons on Massage," by Mrs. Margaret Palmer (manager of the massage department of the London Hospital); "A Handbook of Public Health Laboratory Work, and Food Inspection," by O. W. Andrews, M.B., B.S.; and "A Text-book of Military Hygiene" (with eight plates and 400 woodcuts), by Surgeon-Captain E. L. Munson, M.A., M.D. These two latter volumes are reviewed in our columns this week. Of new editions the same firm are publishing a seventh edition of Allingham on "Diseases of the Rectum"; a fourth edition of Rose and Carless's "Manual of Surgery"; a fourth edition of Sewill's "Dental Surgery"; a fourth edition of Dr. Ball's "Handbook of Diseases of the Nose and Pharynx"; a second edition of Dr. Macnaughton Jones's "Practical Points in Gynæcology"; a second edition of Dr. Oscar Jennings's (of Paris) monograph on "The Morphia Habit"; and a fifth edition of Gadd's "Synopsis of the British Pharmacopœia."

BOOKS, ETC., RECEIVED.

Arrowsmith, J. W., Quay-street, Bristol (Whittaker and Co., 2, White Hart-street, London).

University College, Bristol. Calendar for the Session 1901–1902. Price not stated.

Baillière, Tindall, and Cox, 8, Henrietta-street, Strand, W.C.

Syphilis and other Venereal Diseases. By H. De Méric, M.R.C.S. Eng. Price 5*s*.

Churchill, J. & A., 7, Great Marlborough-street, W.

A Manual of the Practice of Medicine. By Frederick Taylor, M.D. Lond., F.R.C.P. Lond., &c. Sixth edition. Price 16*s*.

Wright, John and Co., Bristol (Simpkin, Marshall, Hamilton, Kent and Co., Limited, London).

Kitchen Physic: at Hand for the Doctor and helpful for Homely Cures. By W. T. Fernie, M.D. Durh., &c. Price 6*s*.

Pulmonary Tuberculosis: its Prevention and Cure. By Professor Carlo Ruata, M.D. Price 3*s*.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Brew, Richard H., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of Health of the Clutton Rural District.

Forbes, William J., M.B., B.Ch. R.U.I., has been re-appointed Medical Officer of Health of Knaresborough Rural District.

Gilmer, H. A. H., M.B., Ch.B. Edin., has been appointed House Surgeon to the David Lewis Northern Hospital, Liverpool.

Livingstone, Thomas H., M.B., Ch.B. Edin., has been appointed District and Workhouse Medical Officer of the Weardale Union.

Mackenzie, F. D. S., M.B., Ch.B. Edin., has been appointed Assistant House Surgeon to the David Lewis Northern Hospital, Liverpool.

Raby, Leonard, M.D. Durh., M.R.C.S. Eng., has been appointed Medical Officer of the Second District of the Devizes Union.

Snow, C. B., M.B., Ch.B. Edin., has been appointed House Physician to the David [illegible] ool.

Stephens, G. A[illegible] has been appointed [illegible] Institution for the [illegible] J. H. Hall.

[illegible] n appointed Medical [illegible] t Chingford, vice T. Sheppard Taylor, resigned.

Watts, Alexander, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Officer of Health of the Holbeach Urban District.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Bradford Royal Infirmary.—House Physician, unmarried. Salary £100 per annum, with board and residence.

Brighton, Hove, and Sussex Throat and Ear Hospital, Church-street, Queen's-road, Brighton.—Non-resident House Surgeon for six months, renewable. Salary at rate of £75 per annum.

Bristol General Hospital.—Assistant House Physician. Salary £70 per annum, with board, residence, &c. Also Physician and Assistant Physician.

Cardiff Infirmary.—Assistant House Surgeon for six months, renewable. Salary at rate of £75 per annum, with board, washing, and apartments.

Chelsea Hospital for Women, Fulham-road, S.W.—Physician to out-patients.

Chichester Infirmary.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

County Asylum, Burntwood, near Lichfield.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, increasing to £200, with board, lodging, and washing.

Denbighshire Infirmary, Denbigh.—House Surgeon. Salary £100, with board, residence, and washing.

East Riding of Yorkshire.—County Medical Officer of Health. Salary £400 per annum, rising to £500, with allowances.

Essex County Asylum, Brentwood.—Junior Assistant Medical Officer. Salary £140 per annum.

Hertfordshire County Asylum, Hill End, St. Albans.—Junior Assistant Medical Officer, unmarried. Salary £160 a year, with board, furnished apartments, and washing.

Hospital for Consumption and Diseases of the Chest, Brompton.—Resident House Physicians for six months. Honorarium of £25 for that period.

Hospital for Women, Soho-square, W.—Assistant Physician.

Lancashire County Asylum, Winwick, Newton-le-Willows.—Senior Assistant Medical Officer. Salary £225 per annum. Also Second Assistant Medical Officer. Salary £175 per annum. Also Assistant Medical Officer. Salary £150 per annum. All with board, lodging, and washing.

Liverpool Infirmary for Children, Myrtle-street.—House Surgeon. Salary £85 per annum, with board and lodging.

Manchester Children's Hospital, Pendlebury.—Medical Officer. Salary £180 per annum.

Manchester Clinical Hospital for Women and Children, Cheetham-hill-road.—House Surgeon. Salary £80 per annum, with apartments and board.

Manchester Southern and Maternity Hospital.—Resident House Surgeon.—Honorarium at rate of £50 per annum and board.

Monsall Fever Hospital, Manchester.—Medical Superintendent, unmarried. Salary £350 per annum, with residence, maintenance, and attendance.

Monkwearmouth and Southwick Hospital, Sunderland.—House Surgeon. Salary £50 per annum, with board, lodging, and washing.

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-upon-Trent.—House Physician. Salary £100 per annum, increasing £10 per annum, with furnished apartments, board, and washing.

North Wales Counties Lunatic Asylum, Denbigh.—Second Assistant Medical Officer. Salary £120 per annum, rising to £160, with board, residence, and washing.

Nottingham General Hospital.—Assistant House Physician. Salary £100, with board, lodging, and washing.

Owens College, Manchester.—Junior Demonstrator in Physiology. Stipend £100, rising to £150 per annum.

Royal Cornwall Infirmary.—House Surgeon, unmarried. Salary £100, increasing by £10 a year, with board and apartments.

Royal London Ophthalmic Hospital, City-road.—Curator and Librarian. Salary £120.

St. Mark's Hospital for Fistula and other Diseases of the Rectum, City-road, London, E.C.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

St. Mary's Hospital Medical School, Paddington, W.—Curator of Museum and Assistant Pathologist. Salary £100 per annum.

St. Pancras and Northern Dispensary, 126, Euston-road.—Physician Accoucheur.

Seamen's Hospital Society ("Dreadnought"), Greenwich, S.E.—House Surgeon. Salary £50 per annum, with board, residence, and washing.

Somerset and Bath Lunatic Asylum, Cotford, Taunton.—Assistant Medical Officer. Salary £120 per annum, rising to £150, with furnished apartments, board, and washing.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Resident Assistant House Surgeon for six months. Salary at the rate of £60 per annum, with board, lodging, and washing.

TOXTETH PARK WORKHOUSE AND INFIRMARY, Liverpool.—Assistant Resident Medical Officer. Salary £100 per annum, with board, washing, and apartments.

VICTORIA HOSPITAL, FOLKESTONE.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

VICTORIA HOSPITAL FOR CHILDREN, Queen's-road, Chelsea, S.W., and the VICTORIA CONVALESCENT HOME, Broadstairs.—House Surgeon for six months. Honorarium of £25, with board and lodging. Also House Physician for six months. Honorarium of £25, with board and lodging.

WANDSWORTH AND CLAPHAM UNION INFIRMARY, St. John's hill, S.W.—Junior Assistant Medical Officer for twelve months. Salary £100 per annum, with board, lodging, and washing.

WESTERN GENERAL DISPENSARY, Marylebone road.—Second House Surgeon. Salary £80 a year, with board, residence, and laundry.

WORCESTER COUNTY ASYLUM, Powick, near Worcester.—Third Assistant Medical Officer. Salary £120 per annum, increasing to £140, with board, residence, &c.

YEOVIL UNION.—Medical Officer. Salary at rate of £60 per annum.

Births, Marriages, and Deaths.

BIRTHS.

BATTERHAM.—On Sept. 13th, at Grand Parade, St. Leonards-on-Sea, the wife of J. W. Batterham, M.B., F.R.C.S., of a daughter.

FERGUSON.—On Sept. 11th, at Woodland-road, New Southgate, N., the wife of R. Bruce Ferguson, M.A., M.D., B.C. Cantab., of a daughter.

HANCOCK.—On Sept. 11th, at Court House, Wiveliscombe, Somerset, the wife of W. Ilbert Hancock, F.R.C.S., of a son.

LAUCHLAN.—On Sept. 12th, at Clapham-road, S.W., the wife of Charles A. Lauchlan, L.R.C.P., L.R.C.S. Edin., of a son.

NEWTON.—At Brook-hill, Sheffield, on 17th inst., the wife of Duncan Gray Newton, M.B., C.M. Edin., of a son.

PANCKRIDGE.—On Sept. 11th, at Petersfield, Hants, the wife of W. P. Panckridge, M.B. Lond., M.R.C.S., L.R.C.P., of a son.

S[illegible] Haslemere, the wife [illegible]

S[illegible] India, the wife of Major D. Simpson, I.M.S., of a son.

SYMONS.—On Sept. [illegible] wife of Captain F. A. S[illegible]

WHICHER.—[illegible] the wife of A. Hastings Whicher, M.R.C.S., of a daughter.

MARRIAGES.

AVENT—NOCK.—On Sept. 17th, at the parish church, Alvechurch, by the Rev. John Avent, M.A. (father of the bridegroom), Arthur Avent, L.R.C.P., to Kate Hurd, daughter of the late J. B. Nock.

CORBEN—OCKENDEN.—On Sept. 17th, at St. George's, Hanover-square, by the Rev. Everard J. Haynes, M.A., Charles Corben, M.R.C.S., to Annie Bulmer, widow of the late E. J. Ockenden, and daughter of the late Major John Godson, Madras Staff Corps.

CRACE-CALVERT—ADAMS.—On Sept. 11th, at Clapham Congregational Church, by the Rev. J. C. Thompson, George Alfred Crace Calvert, M.B., M.R.C.S., to Ellen Marguerite Adams, daughter of Francis Adams.

PICKTHORN—RIDINGS.—On Sept. 12th, at Warblington Church, Hants, by the Rev. W. B. Norris, Staff Surgeon A. J. Pickthorn, R.N., to Florence, daughter of Deputy-Inspector-General W. G. Ridings, R.N. (retired).

PRESTON—READ.—On Sept. 12th, at the parish church, Little Clacton, by the Rev. Frank Bedell, M.A., Joseph Charles Preston, L.D.S., to Janet Mabel, daughter of Thomas Read.

STEVENSON—LAMB.—On Sept. 17th, at St. Mary's Church, Ealing, by the Rev. Dr. Oliver, Walter Brodie Stevenson, M.R.C.S. Eng., L.R.C.P. Lond., to Annie, daughter of William Douglas Lamb.

THORMAN—ADAIR.—On Sept. 11th, at St. Swithin's Church, Bathford, Somerset, by the Rev. H. Byng Tillbrook, William Henry Thorman, M.R.C.S., L.R.C.P., to Jeanie, daughter of the late Major Wallace Adair.

WORTH—SHEPHARD.—On Sept. 17th, at St. John's Church, Eton, by the Very Reverend the Dean of Windsor, Francis James Worth, M.D., B.S., L.R.C.P., M.R.C.S., to Margaret Louisa, daughter of the Rev. J. Shephard, vicar of Eton.

DEATHS.

BALFOUR.—At 15, Marmaduke street, Liverpool, on the 11th inst., Alice, wife of [illegible]

HA[illegible]

ROBERT[illegible]

TRACY.—On Sept. 10th, at Crescent-road, Alverstoke, Hants, Samuel John Tracy, M.R.C.S., L.R.C.P., aged 85 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A WEAK ARGUMENT.

A CORRESPONDENT signing himself "Exoteric" writes to us stating that in a letter which he sent to the *Times* concerning tuberculosis he observed "that the public were entitled to proofs of the transmission of the disease from man to man through the sputum," and exemplified his own case as a proof against the bacteriological origin of pulmonary tuberculosis in that "in his youth predisposed to consumption," and "at that period intimately exposed for months to the perils of the tuberculous sputum" yet he fortunately did not contract the disease. The writer of a leading article in the *Times* did not agree with "Exoteric" in his deductions, and we agree with the writer in the *Times*. "Exoteric's" argument borders on the ridiculous. That "Exoteric" did not become affected with tubercle is no reason why others should not become so. Fortunately for the human race, everybody, even if "predisposed," who is brought into contact with the infective material of tubercle does not contract the disease, any more than everyone who is brought into contact with a case of scarlet fever "catches" that disease. Nevertheless "Exoteric" will scarcely go as far as to say that therefore scarlet fever is not infectious. The sputa of patients suffering from pulmonary tuberculosis have countless times been shown to contain the pathogenic bacilli and to produce tuberculosis in animals. We are far from wishing to create such alarm as will cause all consumptives to be shunned by their neighbours, but we can assure "Exoteric" that the infective nature of tuberculous sputum has been overwhelmingly proved and that the fact cannot be upset simply because he has escaped infection. Every care should be taken in the disposal of the sputa of consumptives, as thereby the danger of the spread of the disease is very greatly lessened.

INSUFFICIENT LAVATORY ACCOMMODATION IN GIRLS' SCHOOLS.

To the Editors of THE LANCET.

SIRS,—The importance of the above question cannot be too forcibly impressed upon parents and guardians now that vacation is ending and school-time recommencing. The evil, for the most part, exists in high-class private schools at fashionable seaside resorts, where probably some 20 to 40 children and growing girls are residing *in statu pupillari*, without counting the teaching staff and the servants. Otherwise liberally and beneficently conducted, the absolute and paramount necessity of providing an adequate number of water-closets is not recognised or met, and habits of irregularity are started and fostered which, in their evil consequence, last a lifetime, and from which arise anæmic and dyspeptic troubles apart from others more vital and serious. As both a parent and a member of the medical profession [illegible] gularity at home, [illegible] habits of irregularity merely from insufficient accommodation. The "constipation" (save the mark!) resulting is then treated medicinally—insult added to injury. Truly, "From the mouths of babes and sucklings learn we wisdom." Let any father or mother question their children and in all probability the veracity of the following statement will be amply corroborated. "We often have to stand in a line after breakfast, waiting our turn. There is a regular rush. Then when my turn comes I don't want to go, and, besides, we must be quick so as to be ready for our morning walk. I often miss a day or two and then I am told to go and ask the governess for pills." Beneficent Nature's impulse thwarted and scoffed at and the vile habit of pill aided peristalsis commenced, never, perhaps, to end as long as life lasts. More searching inquiries will elicit the fact that for about 27 girls, of ages varying from 11 to 19 years and four governesses, but two water-closets are provided. Of these two conveniences one is upstairs and the other is downstairs. The upstair accommodation is, except under special conditions, practically prohibitive; indeed, "the girls lose a mark if found there." Therefore, to the after-breakfast morning call of nature—that most general and important function moment which should never be checked—and within the limited space of time allowed between that meal and the morning walk, for some 27 pupils is provided only one convenience, and, doubtless, even to that access is governed by the school rule of *seniores priores*.

Now, how should this practical and simple illustration of the difficulties which beset our little ones at boarding school be met? That such should not exist is my emphatic opinion, both as medical man and parent. Schools otherwise conducted on irreproachable lines are grievously at fault in this particular, and as a simple but efficacious remedy I suggest that each local governing board should empower and instruct the medical officer of health of the district to visit and inspect all scholastic establishments, and to issue or to forbid certificates to the same until adequate lavatory accommodation is provided per head, on a basis, say, of at least one water-closet to six pupils.

Parents, again, when seeking a school for their girls (boys are generally better provided for) should mentally compare the number of pupils with the lavatory accommodation provided and be guided in their choice of school thereby. How such a type as quoted above derives its being is easily understood. At some favourite resort a private house is taken and some half a dozen or so pupils are installed. At this stage the lavatory accommodation is sufficiently ample, but prosperity and more pupils come, whilst the lavatory accommodation required does not increase *pari passu* with the pupils' advent, and the evils I have endeavoured to point out result.

I am, Sirs, yours faithfully,
HUGHES R. DAVIES, L.R.C.P. Lond., M.R.C.S. Eng.
Bow, E., Sept. 17th, 1901.

"VACCINATION CONCERTS."

A LETTER in the *Times* recently stated that a case of small-pox has occurred in a hop-field in Kent and that, with the view of encouraging vaccination among the hop-pickers who flock to certain parts of that county at this time of the year, the Rev. Richard Wilson, curate of St. Augustine's, Stepney, is holding a series of "vaccination concerts." The concerts take place in the evening in a large marquee on the village green, at Five Oak Green, near Tonbridge, whilst all of the audience who can be induced to undergo the operation are vaccinated in an adjoining tent, the vaccinator being assisted by nurses from the "Little Hoppers' Hospital." Mr. Wilson himself set an example by being vaccinated on the evening of Sept. 7th. This practical method of recommending vaccination has proved very popular with the hop-pickers, large numbers of whom, both adults and children, have submitted to the operation.

OPEN-AIR TREATMENT OF PHTHISIS.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if you or any of your readers can tell me if there is any place in England where the open-air treatment of phthisis is carried out and where the poorer class of patients are admitted gratis or by means of a letter.

I am, Sirs, yours faithfully,
Sept. 18th, 1901. H. H. W. B., L.R.C.P., &c.

⁂ We know of no such institution at present. There are plenty of institutions where patients are received in return for certain payments. In Scotland information might be sought from the Quarrier Homes, Bridge of Weir. Several local authorities in England are building, or are about to build, sanatoria for poor tuberculous patients, but at present the provision for these unfortunate people is very scanty.—ED. L.

INSTRUCTION IN SMALL-POX.

To the Editors of THE LANCET.

SIRS,—As the father of a student at a medical school in London I am surprised that the opportunity afforded by the present outbreak of small-pox in London is not being taken advantage of to enable the students at our hospitals (the medical advisers of the next generation) to acquire a knowledge of the preliminary symptoms and the treatment of this disease, now, fortunately, so rare in its recurrence. This impresses me the more as my son has recently had to go through a fever course at the hospitals of the Metropolitan Asylums Board, which body would no doubt afford similar facilities as regards small-pox. I am, Sirs, yours faithfully,
Sept. 17th, 1901. WM. F. DEWEY.

"THE METHODS OF A PUBLIC VACCINATOR."

To the Editors of THE LANCET.

SIRS,—I have read with interest the circular published in THE LANCET of Sept. 14th, p. 768, which a certain public vaccinator incloses to parents when announcing his intended visits, and also your comments thereon, which, I am pleased to know, condemn the practice. I have recently had brought to my notice the method of another public vaccinator by a patient of mine who called upon me to ask me to postpone the vaccination of her child in consequence of ill-health. I did so and advised her to have the operation performed before the expiry of the two months and so avoid teething time. She then informed me that she was to have it done by the public vaccinator, for he had explained to her when he called the previous week that no medical man in ——— could get the same lymph that he had access to, that he had vaccinated over 3000 cases and "had never had a bad arm," &c. Naturally, I informed her that I, in common with all medical men, could obtain the purest lymph procurable. But whether I have convinced her time alone will enlighten me.

I am, Sirs, yours faithfully,
Sept. 16th, 1901. DISGUSTED.

WINTERING IN THE SOUTH.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me if they know of any family (English or French) in the south of France who would receive into their circle an English lady as a paying guest for the winter? Thanking you in anticipation,

I am, Sirs, yours faithfully,
W. B. BANNERMAN, M.R.C.S.
2, Hemingford-road, Barnsbury, Sept. 17th, 1901.

MEMBRANOUS COLITIS?

To the Editors of THE LANCET.

SIRS,—I shall be grateful if any reader will give me information as to the treatment of a case that I take to be one of membranous colitis. The facts are briefly these. The patient has for two years or so passed small shreds of mucus from the bowel, but as there were no pains except at long intervals (and they were set down to colic) treatment was not sought. About two months ago, however, after a night of abdominal pain, a large shapeless mass of mucus of ivory whiteness was passed, followed in four days by (for the first time) blood. Since then there has been alternating looseness and constipation with almost daily passage of flakes of mucus and on two occasions a little blood, pain being a varying symptom, never very severe and sometimes absent for days together and having no relation to the state of the bowels or the voiding of mucus. The patient has been in India and Africa, but has never had either malaria or dysentery. I shall be obliged also for any references to literature on the subject.

I am, Sirs, yours faithfully,
Sept. 17th, 1901. WORRIED.

PRESERVING THE ELASTICITY OF INDIARUBBER.

DR. D. T. RICHARDS of Risca (Mon.) asks whether we can inform him of the best means of preserving rubber goods from cracking or getting stiff. Another correspondent whose initials and name we are not able to decipher, but who also writes from Risca, asks practically the same question in regard to rubber tubing. The troublesome hardening of rubber, by which it loses its best and essential quality, has been held to be due to the gradual evaporation of the solvent liquids contained in the rubber and introduced during the vulcanising process. Accordingly it has been found that the elasticity of rubber goods may be preserved by keeping them in vessels containing a dish filled with common petroleum. Another expedient is to steep them in a bath of melted paraffin for a few minutes and then to allow them to dry in air heated to 100° C. Smearing with glycerine diluted with water will preserve to some extent the elasticity of rubber tubing.

UNCLE AND NEPHEW.

To the Editors of THE LANCET.

SIRS,—In the little country village where I am practising there is also an unqualified man who carries on a practice as if he were duly qualified. If a case of his assumes a serious aspect an uncle of his who resides some miles away is called, and if death ensues the uncle grants a certificate. On Monday, Sept. 9th, at 1.30 A.M., I was called to see a child whom the father, so he informed me, thought to be dying. I got up and went, and in the course of my inquiries found that the child had been attended for about a fortnight by this unqualified practitioner. I said nothing to the parents then about the child having been attended by an unqualified man, but on seeing the child again at 8.30 A.M. and finding the case almost hopeless I informed the mother that if the child should die I could not give them a certificate. I ought to mention here that before coming to me the father had been to the unqualified man and had told him that the child was considerably worse and that he was afraid it was going to die, and the unqualified man had sent him on to me so that I could give a certificate. The child died early the following morning and the father came down to me and asked me to grant a certificate, which I refused to do, and told him to notify the case to the police. I had occasion to be away on Wednesday afternoon and on returning in the evening I found the following note awaiting me:—

> To Dr. —— 11/9/01.
>
> Mr. ——, the Coroner, states that you ought to have given a Death Certificate To ——— for that Child you have been attending he also says if you dont give one he shall let the athorites know about it. Yours —— ——
>
> P.C. ——

The policeman had called and I not being at home he had left the note for me. The father called on me again that evening, thinking that after receiving the above note I should at once proceed to make ou the certificate. I told him I did not intend to grant one, and the coroner, on being notified to that effect, ordered an inquest for the following day. I was not called to give evidence, but I learned from a juryman that on being asked by the coroner what he was the unqualified man replied that he was an unqualified assistant to Dr. —— of ——, naming his uncle. The coroner in his summing-up to the jury gave them to understand that I ought to have given a certificate and told them it appeared to be a quarrel between the two of us, with which they had nothing to do, being but simply concerned in trying to find out the cause of death. As there seemed nothing to attribute the death to but natural causes he asked them to bring in a verdict accordingly. Considering the attitude taken up by the General Medical Council regarding covering, should I have been doing wrong in granting a certificate in the first place? I should also like to ask your advice what to do in future should I be asked to see a case which has been attended by the unqualified man and is likely to end fatally. Should I be justified in refusing to go at all? I am, Sirs, yours faithfully,
Sept. 17th, 1901. PERPLEXED.

⁂ Our correspondent, in the light of the story whose incidents he relates above, was perfectly right in refusing to give a certificate, and we do not think that the coroner showed due appreciation of the dignity of his ancient office. He should not allow, as he apparently does allow, the village Dogberry to deliver ultimatums like the note quoted It is difficult to lay down any rule for our correspondent's future guidance He is under no legal obligation to attend any private patient, but still his refusal to attend the victims of the unqualified man might cost a life If the facts can be proved to have occurred as stated the attention of the General Medical Council should certainly be drawn to the conduct of the qualified uncle—ED L

W H R—1 The Students Number of THE LANCET, published on Sept 7th, gives full information in an article entitled 'The Student's Library" 2. The books to be read are those recommended in that article for the double qualification of the English Royal Colleges One of the surgical treatises recommended for the higher qualifications should also be read 3 The treatises of Howell and Macbride are the most exhaustive ones in English

R. A B—We see no objection to the circular provided that it be sent out under cover

During the week marked copies of the following newspapers have been received—*Yorkshire Post Bristol Mercury Liverpool Daily Post, Fife Herald and Journal Daily Mail Evening News (Portsmouth) Finsbury Weekly News Leeds Mercury Isle of Man Examiner Ulverston Advertiser, Reading Mercury Windsor and Eton Express, Hertfordshire Mercury Sheerness Guardian Essex County Standard Weekly Free Press (Aberdeen) &c*

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles, and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor

Letters relating to the publication sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS

ote that only those subscriptions
he Proprietors of THE LANCET
W C , are dealt with by them?
on or to local newsagents (with

none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies &c , should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Office, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free either from THE LANCET Offices or from Agents are—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months ..	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR CHARLES GOOD, THE LANCET Office 423 Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates on this or on any other ground should be resisted The Proprietors of THE LANCET have for many years paid and continue to pay the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

Communications, Letters, &c., have been received from—

An original and novel feature of "The Lancet General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in The Lancet.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. Charles Good, The Lancet Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

The Lancet can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

An Address

ON

THE DIAGNOSIS OF CANCER OF THE STOMACH.

By JOHN C. HEMMETER, M.D., PHIL. D.,

PROFESSOR IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF MARYLAND; DIRECTOR OF THE CLINICAL LABORATORY, BALTIMORE, MARYLAND.

IN all efforts at treatment of cancer of the stomach we are confronted by two relentless facts which limit our knowledge and ability. One is of a negative and the other is of a positive nature. The first barrier consists in the fact that we do not know what carcinoma is. We do not understand the nature of malignant neoplasms. The second is that no matter what our methods of treatment, regardless of at how early a date or with what skill it is executed, the cases treated will eventually and inevitably suffer from a recurrence of the disease. This is *an actual fact in 99 per cent. of all gastric cancers that have* undergone operation. With such a state of our knowledge we are condemned to one of three courses. "Either we merely go on to do things just as our fathers did, and for no better reasons than because they did them so; or, trusting to some personal authority, we adopt at random the recommendation of some specific in a speculative hope that it may answer; or, lastly—and this seems the most favourable case—we ourselves attempt to improve upon certain processes and methods hitherto employed." This improvement may follow as a result of accumulated experience, arranged, corrected, and amplified by master minds, or it may be the result of experimental investigation.

In our present knowledge of malignant neoplasms the analytical mind remains in the presence of phenomena the causes of which are hidden from it, but these causes are capable of being discovered and understood, just as the cause of tuberculosis and that of diphtheria were at one time unknown to us and have been shown to be capable of discovery. The only diagnosis that can be of interest to a surgeon is an *early* diagnosis. I have prefaced my remarks in the manner stated in order to emphasise the difficulty of an early diagnosis of any disease the cause of which is unknown and which does not give prompt and unmistakeable clinical manifestations. Many of us can recall the difficulty in the diagnosis of tuberculosis, diphtheria, and malaria prior to the discovery of the specific organisms which were proven to be the causes of these diseases.

Definition of the term "early diagnosis."—The nature and concept of an early diagnosis of carcinoma of the stomach is intimately associated with a knowledge of the duration of the disease, which can be approximately, though not definitely, ascertained by three methods: (1) by observing the rate of growth of carcinomas in organs that are open to direct inspection (the uterus, the rectum, the mammary glands, &c.); (2) by noting the size and rate of growth after the first beginning of the subjective and objective complaints in tumours capable of palpation; and (3) by noting the rate of growth in visible or palpable metastases. Cancer of the stomach may occur and run its entire course in a latent form Osler and McCrae[1] report seven such cases, in all of which I fail to find any statement referring to chemical and microscopical analysis of the gastric contents. It is true the gastric symptoms were not prominent. These cases show that where we have obscure or doubtful diagnosis chemical and microscopical analyses of the gastric contents should be as indispensable as the analysis of the urine in similar cases. But latent cancer has been discovered at the necropsy in my own experience in cases in which frequent chemical analysis of the gastric contents had been made. This occurred in two cases of cancer that arose from gastric ulcers and in which the secretion of hydrochloric acid continued to the end of life and none of [illegible]ptoms of gastric carcinoma were [illegible] history. Such cases, however, [illegible], in my opinion, cases of latent cancer of the stomach will be *reported less and less the more gastric test-meal analysis is* undertaken in obscure cases and the more such analysis is raised to the importance which urinary analysis occupies.

To revert to the duration of this disease, this naturally must vary with the histological nature of the neoplasm. Some neoplasms, such as the scirrhus or the colloid carcinoma, grow rather slowly and also form metastases slowly. From statistics relating to the results of operation it is evident that these two neoplasms are also the most favourable to operation.[2] On the other hand, the medullary or the adeno- or epithelial carcinoma grows more rapidly. In my experience carcinoma of the stomach has, as a rule, a latent period of from three to four months in which it does not give the classical symptoms of gastric cancer but clandestinely progresses under the guise of a chronic gastritis or nervous dyspepsia. This is an important period for the clinician. An early diagnosis means the recognition of gastric cancer during these three or four months, when he is confronted with nothing but the symptoms of chronic gastritis or nervous dyspepsia. Such a diagnosis is unfortunately only rarely possible. The first and main obstacle in the way is that arising from the indolence and procrastination of the patient, and sometimes unfortunately also of the practitioner in charge. The second obstacle is found in the fact that the methods necessary to effect such a diagnosis which are thus far available are *time-robbing*, requiring great patience and persistence and a knowledge of chemistry and microscopical technique only exceptionally met with or capable of application in general practice. A number of guiding principles can be formulated, as much has crystallised out of the study and investigation concerning the clinical history of cancer, which might serve the practitioner as a criterion as to the time when such cases of chronic gastritis or nervous dyspepsia should be transferred to the surgeon But I should like to premise what I shall have to say concerning the chemical and histological technique of the early diagnosis by stating that the simple continuance of a chronic gastritis or nervous dyspepsia, in spite of logical and scientific treatment accompanied with progressive loss of body weight during from three to four weeks, are two factors which alone justify the suspicion of a latent gastric carcinoma.

The ingenuity, the immense amount of investigation, and the indefatigable perseverance which have been bestowed upon the chemical and histological methods of diagnosis of gastric carcinoma cannot but excite universal admiration. But in my experience they are of no greater help to the clinician for the recognition of this disease than are the simpler continuance or even aggravation of a chronic gastritis and progressive loss of body weight (though every other symptom and sign may be lacking) in spite of proper treatment.

I will consider *seriatim* the various clinical methods employed for the detection and recognition of carcinoma of the stomach. I will employ the right of the conservative clinician—viz., the critical faculty of determining the actual value of these aids and the deduction of practical conclusions from their association.

Age.—According to the tables of Brinton (600 cases), Welch (2075 cases), and Haberlin (11,424 cases), three-fourths of all cases of gastric cancer occur between the ages of 40 and 70 years The factor of age should, however, be used only with the greatest caution. Of 66 cases of Lindner and Kuttner, more than one-half of the patients had not reached the fiftieth year. The same can be said of Hammerschlag's cases. I have repeatedly had the experience that general practitioners have failed to recognise cancer of the stomach on account of the youthful age of the patient. Now, Wilkinson has reported a case of congenital gastric cancer, Cullingworth one in a child five weeks old, Widerhofen a congenital cancer, and Kaulich a colloid carcinoma in a boy one and a half years old. According to Schäffer, the percentage of gastric cancers in the first three decades is 2, according to Reichert 3, and according to Bräutigam 2·5.[3] One fact which I should like to emphasise in connexion with the question of age is that the limit of age for carcinoma is gradually receding.

Diagnostic value of the subjective and objective symptoms.—Among all the *dyspeptic* complaints, the disturbances of the appetite, the thirst, the pressure, the distension and fulness,

No. 4074.

the eructation, the nausea and vomiting, and the irregularities of the stool, there is nothing characteristic. Thirst is a particularly prominent and a very annoying symptom in dilatations caused by pyloric carcinoma. There is nothing characteristic about the pasty, insipid taste, or about the coated tongue. The pains are not characteristic. The vomiting and nausea, when very frequent and copious, are suggestive of cancer at the pylorus of the cardia. When the two openings of the stomach are free and only the walls of the stomach are affected there is in my experience no vomiting at all. The amount that is vomited depends on the degree of dilatation. The food is unchanged.

Significance of blood and hæmatemesis.—In my experience blood is contained in the vomit of one-half of all cases of gastric cancer. Large quantities of blood are rarely vomited, but the characteristic coffee-ground vomit in consequence of stagnation and decomposition of the blood is diagnostically important. The more copious the effusion of blood is into the stomach the quicker does it cause vomiting; for that reason the abundant hæmorrhages in ulcer are often vomited uncoagulated and very little altered, whereas the smaller amounts of blood in carcinoma and gastritis remain in the stomach a longer time and then show the characteristic coffee-ground appearance. But large hæmorrhages may occur in cancer and small hæmorrhages may occur in ulcer; and I have seen cases of coffee-ground vomiting in ulcer repeatedly.

Constipation or diarrhœa.—In the literature of this subject in which any reference to these points was made I found that in 75 per cent. of cancers of the stomach there is constipation. In about 20 per cent. there is diarrhœa and in 5 per cent. only does the stool remain regular. These figures agree with those from my clinic sufficiently to make any alteration needless. F. Müller states that diarrhœa occurs in 35·5 per cent. The greater frequency of constipation is due to the mechanical stenosis by the tumour, and motor insufficiency is due to carcinomatous invasion of the muscularis.

Emaciation and cachexia.—That these symptoms are not characteristic is evident, but they are important because the degree of emaciation will greatly influence the decision on an operation. A frequent question will be, Will the strength of this patient suffice to overcome a severe abdominal operation? The general condition gives no clue to the size of the tumour. A very minute cancer, even when it is at a place where it in no way influences the functions of the body, may depress the nutrition of the entire organism and irresistibly lead to death. On the other hand, very large tumours on the walls of the stomach may run a long course without disturbance of the general strength and nutrition. So in all dyspeptic systems there is nothing pathognostic for gastric cancer. They occur not only in other diseases of the stomach but to a large extent in diseases of other organs. The swelling of the cervical lymph-glands is a very rare sign, and in my experience occurs only towards the end of the disease, by which time the diagnosis is generally clear.

Condition of the gastric functions.—Alterations in secretion, absorption, and peristalsis. (1) The secretion. During the development of cancer secretion of hydrochloric acid is generally lost, so that free hydrochloric acid can no longer be detected in the test meals. Towards the end stage both free and combined hydrochloric acid are entirely absent. It is urgently necessary to be very careful in these determinations for hydrochloric acid. A single analysis showing sub- or an-acidity proves nothing at all. If a first test fails to detect free hydrochloric acid it should be repeated after allowing a longer interval to elapse subsequently to the time at which the test meal was taken. It must be borne in mind that the gastric mucosa does not secrete hydrochloric acid all over—i.e., in all of the parts. Only the middle portion secretes it; the pyloric region does not secrete it. Although the degree of reduction of hydrochloric acid secretion depends upon the extent and gravity of the gastritis which is caused by the carcinoma, nevertheless this may be limited to the pyloric region, where it will not interfere with the glandular apparatus which forms the hydrochloric acid. F. Mall[4] concludes with Heidenhain that the oxyntic or border cells in the peptic ducts are concerned in the production of hydrochloric acid and the central cells in the production of pepsin. Now as the pyloric region contains no border cells a carcinoma may reach as far as the antrum pylori, a distance of from three to five inches, before it will invade the region which contains the acid or border cells. I have seen six cases in which the presence of free hydrochloric acid continued to the end of life. In two of these cases the carcinoma was seen during the operation and in the remaining four at the necropsies. These six cases had not originated on the basis of an old gastric ulcer, but were circumscribed knots of cancer, leaving the mucosa largely intact. In all carcinomas that have arisen from ulcers free hydrochloric acid in normal or even in increased amounts may continue until death. This is sufficient evidence for the conclusion that the presence of free hydrochloric acid does not argue against cancer of the stomach. On the other hand, absence of free hydrochloric acid is no specific sign of this disease. It occurs in other gastric diseases leading to atrophy; it may occur in diseases of other organs—for instance, diseases of the kidneys, pulmonary tuberculosis, and valvular cardiac diseases, and, as I have shown,[5] free hydrochloric acid is frequently absent, though not necessarily so, in catarrhal jaundice. When free hydrochloric acid is absent combined hydrochloric acid may still be present; and Schüle argued that the amount of hydrochloric acid deficit was an important diagnostic sign between cancerous and benign diseases of the stomach.

In determining the amount of hydrochloric acid deficit decinormal hydrochloric acid solution is added to the filtrate of gastric contents until we get a distinct reaction with the Boas resorcin test or any of the other established tests for free hydrochloric acid. The degree of the deficit is, in my experience, no indication of the extent of the atrophy of the secreting apparatus. Very large hydrochloric acid deficits have been discovered by myself in benign diseases of the stomach. The determinations for hydrochloric acid, however, when taken in conjunction with other symptoms and signs, have a certain limited diagnostic significance.

Secretion of pepsin and chymosin or rennin.—As a rule, the reduction of the secretion of these ferments goes parallel with a reduction of the hydrochloric acid secretion. For clinical purposes the determination of the presence and strength of the pepsin secretion may be made according to the method of Hammerschlag,[6] though this method from a chemical standpoint is by no means exact. Hammerschlag used the Esbach albuminometer to determine the amount of albumin which has not been digested by the pepsin of the gastric contents. As this method is not exact when used for urinary analysis it is less so for this purpose. Still, as a rough clinical test it generally suffices. A 1 per cent. solution of albumin containing free hydrochloric acid to the amount of 4 per 1000 is filled into the Esbach albuminometer to the 10 cubic centimetres mark. To this tube we add five cubic centimetres of the gastric filtrate to be tested for pepsin. A second Esbach albuminometer is filled to the 10 cubic centimetres mark with the standard egg albumin and hydrochloric acid solution, and as a control test five cubic centimetres of distilled water are added. Both tubes are now put in the incubator at a temperature of 37° C. for one hour. Then the amount of albumin in each is determined by the Esbach reagent. After both tubes have been allowed to stand quietly for 24 hours the amount of digested albumin can easily be calculated in numbers expressing the percentage. This test is not sufficiently delicate to demonstrate small amounts of pepsinogen. The reduction of the chymosin or rennin occurs in all gastric carcinomas except those arising from gastric ulcers, but very marked reduction of the amounts of both ferments is in itself not a characteristic sign for gastric cancer, because it can occur in atrophy of the mucosa from gastritis and also from long-standing diseases of other organs.

Lactic acid.—In 112 cases of carcinoma of the stomach I found only three in which lactic acid was present to any considerable degree before the diagnosis could be made by other symptoms. The frequent occurrence of lactic acid in gastric cancer has been asserted by Boas to be an important diagnostic sign. The question is, Does it occur at a time to enable us to make an early diagnosis? This I must deny on the basis of a large experience with this test. Boas has admitted that excessive lactic acid in the stomach contents is not a pathognostic sign of cancer of the stomach because it is absent in a number of cases of that disease and may be present in gastric diseases of a benign type and even during diseases of other organs. Three conditions are necessary, possibly four, to bring about excessive formation of lactic acid in the stomach. These are: (1) impaired gastric motility; (2) absence of hydrochloric acid secretion; (3) reduction of albumin digestion; and (I should add) (4) an impaired absorption. Lactic acid is formed in the stomach by the action of lactic-acid bacilli on the carbohydrates. Sticker has shown that the simple passage of carbohydrates through the mouth causes the formation of more or less lactic acid without exception. It is therefore necessary to give a test meal which shall be as far as practicable free from lactic acid and which shall form little of this substance during the passage through the mouth. Such a test meal has been introduced by Boas in the form of his oat-flour soup (one ounce of Knorr's oat flour boiled in a quart of water, evaporated down to one pint and seasoned with salt only). Lactic acid will not form in the stomach in amounts demonstrable by Uffelman's test, even though the contents stagnate due to arrest of the peristalsis, provided the proteid digestion is still fairly good and does not fall below 75 per cent. Whenever there is much lactic acid in the stomach the proteid digestion will be found to be below 75 per cent. I have made a number of chemical tests relative to the relation of lactic acid to proteolysis and have confirmed the view that lactic acid may replace the normal hydrochloric acid in this transformation. In the contents of some carcinomatous stomachs the lactic acid was found to be in combination with the proteid of the food. When the mucosa is still capable of secreting hydrochloric acid this will combine with the albumin sooner than the weaker acid, hence a fairly good albumin digestion signifies still a trace of hydrochloric acid and ferments. But a fairly good albumin digestion can be effected by lactic acid and pepsin in the absence of hydrochloric acid. This chemical fact merits closer investigation. Normally lactic acid, like all other soluble products of digestion, is absorbable. If, therefore, the absorption is made difficult, which occurs especially when the contents stagnate and the hydrochloric secretion is depressed, the conditions favourable to lactic acid accumulation will be present. Whenever the movements of the stomach are normal, so that the contents can be expressed into the duodenum within six or seven hours, lactic acid will not develop to a degree that can be recognised by the ordinary tests, although the hydrochloric acid secretion has been lost entirely. Hammerschlag took such a gastric chyme containing no hydrochloric acid, but from stomachs with normal motility, and added the third necessary factor—viz., stagnation—by letting it stand at room temperature. Under such stagnation lactic acid rapidly developed in the chyme. In gastric carcinoma we have the conditions favourable to lactic acid formation in the majority of cases—vide suppression of hydrochloric acid, stagnation of contents, impaired proteid digestion, and impaired absorption—so that lactic acid is found most frequent in cancer of the stomach. Rosenheim found it in 78 per cent., Lindner and Kuttner found it in 60 per cent., Strauss found it in 91 per cent., and I have found it in 82 per cent. of all my cases of gastric cancer. But the conditions necessary to its formation in the stomach can be brought about by diseases other than cancer; for instance, in benign pyloric stenosis, in atrophic gastritis with motor insufficiency, and even in diseases of other organs I have discovered lactic acid in the stomach in marked excess when the stomach itself was not affected, but the impaired peristalsis was caused in one case by a pancreatic cyst, in another by a carcinoma of the gall-bladder, and in a third case by a large gall-stone. These conditions had caused compression of the duodenum effecting obstruction to the outlet of gastric chyme with a subsequent gastritis, the latter most probably causing the loss of hydrochloric acid secretions. In still another case in which there was a compression of the duodenum by floating kidney the presence of lactic acid was only transient. Whenever the kidney could be retained in place by a proper bandage the stomach resumed its secretions partially and the peristalsis was to a degree resumed, and the lactic acid, except in minute traces, disappeared from the contents. Lactic acid, then, although it is not an early sign, is a clinical [illegible] ns absence of hydrochloric acid, [illegible] the digestive ferments and loss [illegible] hich are most [illegible] lactic [illegible] when it [illegible] uggest the probability of cancer. The test necessary for this which is most practical is the one originally suggested by Uffelman. The reagent consists of 10 cubic centimetres of a 4 per cent. solution of carbolic acid, 20 cubic centimetres of distilled water, and one drop of the liquor of the sesquichloride of iron. This gives an amethyst-blue solution. The presence of lactic acid changes this to a yellowish green. The reagent is sensitive to 0.5 per 1000 of lactic acid, which amount is always pathological and of diagnostic significance. Tests more sensitive than this would not be useful clinically. Boas[7] has given an exact method for quantitative determination. Strauss[8] has devised a practical little funnel for separating the lactic acid by agitation with ether.[9]

[illegible] s detached; many [illegible] merge the identity [illegible] rim of protoplasm [illegible] of a huge vacuole. There are in both [illegible] disrupted chromo- [illegible] st cell presenting [illegible] their name from [illegible] ical mitosis is one [illegible] number of chromosomes.

Microscopical examination of the stomach contents.—There are only two structural elements in the stomach contents that have a possible diagnostic significance. These are (1) tissue fragments, minute portions of the neoplasm; and (2) the so-called Oppler-Boas bacilli. The tissue fragments are of undoubted diagnostic value if they contain structure of the neoplasm. The question is, Do they occur early enough in the disease to make a timely diagnosis possible?

[7] [illegible] Wochenschrift, 1893, No. 23.

[8] [illegible] No. 37.

[9] For [illegible] Stomach, recent edition, p. [illegible]

It is probable that the fragments are only detached from ulcerating tumour masses in the stomach such as have already developed metastases, but I shall describe a method—that of curetting the walls of the stomach with a soft tube and thereby loosening the superficial epithelium at a time when the neoplasm is not yet ulcerating. These fragments can be washed out of the stomach by lavage and sedimented in the electric centrifuge. I have used this method in 48 cases of gastric carcinoma, and I regard it as eminently important and adapted to early clinical diagnosis. I wish to emphasise that not only fragments of the neoplasm itself are to be sought after, but any cellular tissue that is found should be carefully stained and studied The most remarkable feature of the sediment from such a stomach after this so-called curetting is a large number of cells presenting karyokinetic figures. Rieder[10] reported a case in which he made a diagnosis of malignant disease of the peritoneum and pleura from finding numerous cells in the exudates, showing indirect and atypic nuclear division. Mitoses occur very frequently. The forms of cell and nuclear division known as the equatorial plate and the monaster are frequent. Another form known as the anaphase, which in normal karyokinesis precedes the formation of the daughter stars and leads up to the formation of resting daughter nuclei, I have observed three times in the curettage from stomachs at a stage when there was no tumour palpable and in which the diagnosis was confirmed by operation, necropsy, or by the later development of a tumour. The presence of a large number of cells in the stomach after curetting with the stomach-tube, which cells show mitosis, and some of them pathological or asymmetrical mitosis, is very significant and should stimulate further and very careful examination. Sooner or later a fragment will be obtained which will give the typical structure of carcinoma. For this kind of curetting a soft stomach-tube suffices provided it has a lower and a lateral aperture the edges of which scrape away the tiny elevations of gastric mucosa when the tube is moved in and out of the mouth. The procedure should be carried out in the morning before breakfast when the stomach is empty. This method of obtaining specimens from the gastric mucosa during life is free from danger and not once in my experience has any pain, distress, or hæmorrhage been produced thereby. In many cases of chronic gastritis, achylia gastrica, and carcinoma tissue fragments are found in the lavage water without especially making an effort to loosen them, by moving the tube along the gastric walls. The forcible detachment of larger pieces of gastric mucosa is an accident occurring during lavage by suction or aspiration of the tube, particularly when the instrument is in inexperienced hands. It is followed by copious hæmorrhage, yet pain is rarely complained of. I reported a case of one of my students[11] who aspirated a piece of his own gastric mucosa 10 by four millimetres; it was followed by a profuse hæmorrhage but no other serious consequences, as uninterrupted recovery occurred under rest and liquid diet.

The Oppler-Boas bacilli are very long, rod-shaped organisms, non-motile, and usually thicker at one end than at the other, presenting the shape of a base-ball bat. Kauffmann and Schlesinger[12] have isolated these organisms and have asserted them to be of great significance in cancer of the stomach. Riegel[13] confirms the occurrence of these bacilli in enormous numbers in carcinoma and adds that although there are numerous fungi that have the property of forming lactic acid in stomach contents this cannot alter the significance of the Kaufmann and Schlesinger observation. He does not consider these organisms as pathognomonic of gastric cancer but as very important for the diagnosis. Dr. Harry Adler and myself have examined 56 cases for the Oppler-Boas bacilli and have failed to observe them in only three cases. The presence of this organism is therefore an important factor, aiding in the diagnosis; and whilst not pathognomonic they are of the same diagnostic value as the presence of lactic acid, and therefore do not constitute an early sign of cancer.

Microscopical evidences gained from the contents or the walls of the stomach.—In the preceding part of my address I have briefly outlined my opinion concerning the diagnostic value of subjective and objective signs and symptoms; of the various ways and degrees in which the three functions of the stomach, peristalsis, secretion, and absorption, can be altered; and of the value of the chemical and microscopical examinations of the urine, the blood, and the gastric contents. There is therefore not one clinical sign or symptom, chemical or microscopical evidence, which is characteristic or pathognomonic for the fully-developed gastric carcinoma, not to speak of the value of these conditions and symptoms for the early diagnosis. We are therefore compelled to seek further evidences from which we may hope to obtain information. One of the first and indispensable steps towards the attainment of new truth is to admit the helplessness of our present knowledge and the inadequacy of our present means of diagnosis. I have attempted to enlarge the diagnostic technique in this respect by efforts at obtaining histological fragments of gastric mucosa by curetting the walls of the stomach with a stomach-tube.[14] After this curetting the stomach is washed out with a measured quantity of water. If the particles detached from the gastric mucosa are not visible to the naked eye this lavage water is sedimented in the centrifuge and the sediment is examined microscopically. It is not sufficient to look simply for particles of the actual structure of the malignant tumour in the wash-water. One may occasionally have the good fortune to arrive at a positive diagnosis by finding actual structural fragments of an existing carcinoma. but in my experience such an occurrence always speaks for a neoplasm that has already progressed very far and which can be diagnosed by other methods without gastric curetting. Structural fragments are only detached from ulcerating tumour masses in the stomach, and in all the cases in which I succeeded in getting such fragments metastases had already formed and the diagnosis could not be called an early one. The finding of actual tumour masses, then, is comparatively rare, and while it firmly establishes the diagnosis of carcinoma of the stomach is of no value to the surgeon in his efforts to secure an early operation. In curetting a very large number of stomachs for the purpose of studying the histological condition of the mucous membrane I have been led to hope for some aid to an early diagnosis by a study of the pathological and atypical mitoses that occur in the gastric structure. The finding of pathological mitoses, and even of carcinomatous particles, is considered to be an accident by a number of competent observers, but it is probable that this occurrence is said to be so rare, not because these fragments do not occur in the vomit or wash-water, but because they are not methodically and systematically looked for, and especially because few directed efforts have been made by competent men to detach such fragments intentionally from the gastric mucosa. There is every reason why we should intentionally attempt to secure such particles from the stomach, just as they are secured by curetting the uterus. Hitherto in such examinations the histologist reserved his opinions, as a rule, until he found the typical structure of a carcinoma in the tissue fragments gained. But it is possible to go a step farther and to diagnose this disease from fragments showing the following conditions: (*a*) the ducts of the peptic glands are elongated and dilated, the cells frequently detached from the periphery of the gland and lying loose in the gland lumen and presenting numerous karyokinetic figures (Fig. 1); (*b*) when these nuclear figures, or mitoses, present asymmetrical or hypochromatic and hyperchromatic forms they are especially suggestive of a malignant process. (Fig. 2 and Fig. 3.) These mitoses must be examined in tissue that is as fresh as can be obtained; where the least decomposition has taken place they are no longer demonstrable by tinctorial methods. For this purpose curettage of the stomach is indispensable, as the tissue fragments gained by other methods, vomiting or simple lavage, are, as a rule, in a state of necrobiosis. The result of the procedure of curettage is made more reliable if the patient is fed by the rectum for a time and all food is excluded from the stomach. Wherever possible the stomach should be thoroughly washed out for several days in succession in order to avoid confounding particles of meat, &c., retained in the ingesta with particles of neoplasm. The diagnosis of malignant disease of the peritoneum and pleura from numerous cells found in the aspirated exudate, which cells were in the state of indirect nuclear division, was probably first definitely made by Rieder.[15] The necropsy in

Rieder's case proved the existence of a sarcoma of the peritoneum secondary to malignant disease of the ovaries. In the fluids obtained during life cells were found which were remarkable, in the first place, on account of the difference in size and shape of the individual cells. Often there were indentations and constrictions, sometimes buddings. In many cells there were one or many vacuoles, often so large that the nucleus was pushed to one side and sometimes almost completely submerged beneath the enormous vacuole. Examination of the stained cells showed a large number of cells in a state of indirect division and especially cells with atypical mitoses. George Dock[6] made similar studies and established the diagnosis of carcinoma of the pleura and peritoneum from analogous cellular forms found in the aspirated transudate. Asymmetrical mitosis is not easy to recognise in fragments gained from the gastric mucosa on account of the frequent imperfect preservation of the chromosomes in many cases. Many fragments are found which are useless for the purpose of studying pathological mitoses for this reason. The methods and technique are fully described in my text book.[17]

In a number of German publications I have noticed the definition of *early* diagnosis to the effect that the disease is recognised before a tumour can be felt. As fully two-fifths, according to some authors one-half, of the tumours of the stomach are not palpable it is evident that this is not a reliable sign to go by. Tumours may be very large and may be not at all palpable. The palpability of gastric tumours depends too much upon the situation of these neoplasms in the stomach, although 60·8 per cent. of the tumours observed at necropsies by William H. Welch[18] were situated in the pyloric region; all of these tumours were not palpable. It is only when [illegible] displaced downward by [illegible] that it becomes [illegible] quite a number of tumours of the pylorus at necropsies which were by no means palpable during life owing to the fact that the tumour was adherent to the under surface of the liver.

In an investigation on the pathological anatomy of the human stomach with a special reference to the practical value of diagnosis by means of fragments of the mucous membrane Leuk[19] holds that it is not possible to distinguish between carcinoma and atrophic gastritis by examining such fragments unless portions of actual carcinomatous growth are found. He does not go into the consideration of the relative frequency of the findings of cells showing atypical and asymmetrical mitoses in the contents of the stomach or gained after gastric curettage. But few investigators have as yet worked over this subject, as may be seen from the literature in my articles[20] and in the second edition of my text book on "Diseases of the Stomach." The whole subject is not sufficiently mature to permit of the enunciation of dogmatic conclusion either way. I wish simply to emphasise that the diagnosis of carcinoma of the stomach *has* been made in this way at a time when we had every good reason to believe that it was an early diagnosis and that this opinion was confirmed either at operation or at the eventual necropsy. Leuk's work in my opinion is not based upon a sufficiently large number of clinical observations as might be desirable for the importance of this question. It is confessedly a rare thing that the diagnosis of carcinoma of the stomach at an early stage can be made in this manner; this I explain on two grounds: (1) it is rare that patients present themselves at an early stage for examination; and (2) the method of gastric curettage is rarely practised. I am of the opinion that as the method comes more and more into use we may hear of a larger number of early diagnoses of this disease being made.

Wherever appreciable quantities of lactic acid are regularly found in the *stomach together with the signs*

motor power of the stomach may remain normal throughout the course of the disease. There are even rare cases of pyloric cancers in which motor power may remain intact for a long time.

Absorption.—The tests for the absorptive power of the stomach usually give evidence of great reduction in this function. There are, however, many exceptions to this rule, no doubt due to the fact that the gastric mucosa is in a fairly normal condition, notwithstanding the presence of a very circumscribed carcinoma.

Urine.—Investigation made hitherto on metabolism and the constituents of the urine have, in my opinion, not as yet yielded any results of practical value for the diagnosis. Albumin is present in from 35 to 50 per cent. of the cases according to F. Müller. Excess of indican is present in from 85 to 90 per cent. of the cases.

Blood examinations.—These have shown a reduction in the percentage of hæmoglobin and absence of the digestive leucocytosis. Frederick P. Henry has emphasised the fact that in gastric carcinoma the red corpuscles number from 2,000,000 to 3,000,000 per cubic millimetre, whereas in pernicious anæmia, which most resembles cancer of the stomach, the count is much lower, sometimes less than 500,000.[21] This phenomenon will serve to distinguish these two diseases. The number of erythrocytes is not proportionate to the degree of cachexia. In this opinion Henry has been confirmed by Dr. Anton Krokiewicz.[22] My personal experience is that the numerical relations of the cellular elements of the blood are too variable to constitute a reliable diagnostic factor in gastric carcinoma.

Tumour.—Demonstration of a tumour in the stomach is the most reliable evidence upon which to base a diagnosis, but it is not an early diagnostic sign. According to various prominent German surgeons the presence of a tumour is a contra-indication to the execution of a radical operation, having in view the total extirpation of the neoplasm. Czerny and Rindfleisch[23] and Kraske[24] argue that gastric cancer should not be radically operated upon after it can once be diagnosed in the form of tumour. It will not be necessary for me to consider the methods of palpation and the mobility of gastric tumour, but I should like to recommend urgently the palpation of the patient, either in a warm bath or under anæsthesia, when a tumour cannot be made out by palpation under ordinary conditions.

Hypertrophic stenosis of the pylorus; stenosing gastritis.—The differential diagnosis between this condition and carcinoma is difficult. W. S. Thayer and Rosenheim have reported cases of benign stenosis that could not be distinguished from carcinoma. A history of very long-standing dyspeptic disease, with alternating improvements and aggravations, speaks for hypertrophic stenosis if the symptoms and anamnesis of chronic gastritis accompanied the development of the stenosis. The presence or absence of tumour is of no diagnostic value in differentiating these two conditions. A tumour when present may as well be a benign hypertrophy as a cancer. Repeated and consecutive weighing of the patient is urgently indicated in benign hypertrophic stenosis; there will be more frequent and more lasting improvements, extending sometimes through years. Motor function and stagnation grow progressively worse in carcinoma; in benign stenosis they are amenable to treatment by lavage and diet.

In stenosis due to cicatrix from gastric ulcer there will have been a history of blood in the vomit or stool and the presence of excess of hydrochloric acid in the gastric chyme; if the stenosis is due to hypertrophic gastritis these signs will not be observed, though a normal amount of hydrochloric acid may exceptionally be met with in the early stages of the latter.

Among all the early signs and symptoms of gastric carcinoma, the dyspeptic symptoms and the evidences of disturbed functions, and the general condition, there is not one fact that is pathognostic for an early diagnosis. I do not assert, however, like Haberkant, Lindner, and Kuttner, that in the present state of our knowledge the early diagnosis of gastric carcinoma is entirely impossible.

Diseases of the stomach associated with the absence of hydrochloric acid.—A brief consideration of these will be indispensable in our efforts to reduce the possible sources of error in making a diagnosis. The atrophies that may be associated with the absence of hydrochloric acid are the following: (1) apparently idiopathic (Nothnagel and Fenwick); (2) end stages of long-standing chronic gastritis; (3) gastric atrophies occurring with mammary, uterine, and intestinal carcinoma; (4) with benign pyloric stenosis; and (5) with gastric cancer.

Achylia gastrica, which has been first described by Einhorn in 1888, means the complete absence of the secretion of gastric juice, not simply hydrochloric acid only, but also of the ferments. So-called anacidity, or achlorhydria, means the absence or loss of hydrochloric acid, but pepsinogen and rennin zymogen are still secreted. Achylia gastrica may be congenital. The existence of so many conditions connected with the absence of hydrochloric acid is an evidence of the difficulty of utilising this sign for diagnosis. In Groups 1 and 2, however, the motility is normal; there is, as a rule, no lactic acid formation, and the course of the disease is generally a long one. The atrophies described by Fenwick under Group 3 have not been as yet carefully studied with regard to their motility and the presence or absence of lactic acid. Group 4, the benign forms of pyloric stenosis, are very rare, but they can be distinguished by their long, slow course. If, therefore, the history extends over several years no importance can be attached to the presence of lactic acid. Achylia gastrica is also a disease of long duration; the motility is always excellent, the appearance of the patient is good, and the condition of the chemistry of the stomach is always the same, showing no lactic acid, no ferments, and no hydrochloric acid.

Neuroses of the stomach associated with permanent or temporary loss of hydrochloric acid secretions.—These conditions are very often perplexing and might be confused with the diagnosis of cancer, but the presence of hysteria or neurasthenia and the long duration of the disease, together with the result of curetting of the stomach for fragments of mucosa, should make the differentiation possible. Patient observation will eventually detect a period in the course of neuroses when hydrochloric acid is again secreted normally. A neurosis during the course of which a perfectly normal secretion may alternate with anacidity (even achylia), and, on the other hand, with hyper-acidity or super-secretion, was first thoroughly investigated at my clinic. I have proposed the name "heterochylia" for this condition.

Gastroscopic examination.—Whether the gastroscope will enable us to make an early diagnosis of gastric carcinoma is a very remote problem. Gastroscopy has no doubt made distinct advances during the last 10 years, but it is connected with so many difficulties and dangers that the general application of this method cannot be hoped for at present. Mikulicz, Kelling, Rosenheim, Revidzoff, and Kuttner have published their studies on gastroscopic examination of the stomach. After a critical study of their reports one cannot fail to be conscious of discouragement at the absence of practical results. There is still very little promise in this method.

Electrodiaphany or transillumination of the stomach, according to the method first suggested by Einhorn, may give a suggestion of the existence of a tumour of the anterior gastric wall, but a chance of such a demonstration will be very small. Out of 1300 cases of cancer of the stomach collected by W. H. Welch[25] only 30 occurred on the anterior wall—i.e., 2·3 per cent. In order to cut off the rays of the intragastric lamp a tumour must have a thickness of from 1·5 to two centimetres.[26] These observations have been confirmed by me. With a tumour of such dimensions as a requisite and the extreme rarity of the location of tumours on the anterior gastric wall I am disposed to consider this method unavailable for the early diagnosis.

The use of the x rays for diagnosis.—I was among the first to publish studies of the position and size of the stomach for diagnostic purposes.[27] Boas and Levy-Dorn[28] have proposed a method of recognising strictures of the gastro-intestinal canal by skiagraphy. Capsules coated with an insoluble material and filled with bismuth subnitrate cut off the x rays and their position can be recognised in the intestines, but I doubt very much whether this method will exactly locate a carcinomatous constriction because the intestine is not a simple tube but a labyrinth of convolutions superimposed upon each other, so that even if the bismuth capsule could be recognised it is absolutely impossible to state whether it is in the stomach or in the intestine or in what convolution of the intestine it is located

Exploratory laparotomy —This diagnostic incision I would warmly recommend in all cases of gastric disease associated with (1) rapid emaciation, (2) absence of hydrochloric acid, (3) reduction of proteid digestion under 30 per cent, and (4) the presence of lactic acid by Uffelman's test, or (5) of numerous long baseball bat shaped Oppler Boas bacilli If all of the above signs and symptoms were present in any case even of short standing and recent beginning of the disease, and no improvement followed three weeks of appropriate treatment, I should feel justified in making the diagnosis of carcinoma of the stomach even in the absence of tumour and should urge an exploratory laparotomy

Albert Albu[39] reports a very interesting case in which the exploratory laparotomy revealed an infiltration of the pylorus which, in his own words, was no thicker than a small chestnut and proved after a resection of the pylorus, to be cirrhus This patient had an acute attack of tetany Recovery after pylorectomy was satisfactory and the motor function of the stomach was restored In this case the diagnosis was not certain before exploratory laparotomy had been undertaken The early diagnoses and early operations are extremely rare in the literature of the subject due to the reasons which I have already stated—viz., that the patients do not present themselves in time and that the methods which are most promising for an early diagnosis are either neglected or permission for their execution is refused by the patient The most important information from all the physical signs and symptoms and from the chemical and microscopical investigations may be arranged in order of their diagnostic value as follows, but I do not desire to be dogmatic in this statement 1 Chronic gastritis or nervous *dyspepsia with progressive aggravation in spite of four* weeks' proper treatment 2 Progressive weakening of the peristaltic power This can only be confused with the benign stenosis of the pylorus but in the latter case (the benign stenosis) there is, as a rule, a normal or an excessive amount of hydrochloric acid. In malignant stenosis there is absence of hydrochloric acid and formation of lactic acid The diagnosis between benign and malignant stenosis may be difficult at the beginning of the clinical observation of any case, but after from two to four weeks of observation it should present no difficulties 3 Progressive diminution in the amount of free hydrochloric acid with steady loss of peristaltic power 4 The presence of large numbers of atypical and asymmetrical mitoses after gastric curettage together with characteristic histological changes in the glands previously described (especially in cases of motor insufficiency) With such clinical indications exploratory laparotomy should be undertaken, and where this step proved the diagnosis to be wrong, in my experience it was discovered that conditions were present which necessitated operative interference anyway, such as, for instance, motor insufficiency from cicatrices, indurated ulcers or adhesions

In this schema the diagnostic value of the Oppler Boas bacilli, tumour, and lactic acid are not referred to because they are late signs I do not wish to be understood to say however, that a surgical operation should not be undertaken when these late signs are present Many times even the presence of a tumour is not a contra indication to an operation, because a malignant tumour in the stomach may be present, as I have noted on three occasions, and no signs of metastases of infection of the lymph glands be discoverable by a careful search at the necropsy

The diagnosis of carcinoma of the stomach is still in its elementary rudiments We do not know what the causes and nature of malignant neoplasms are The diagnosis of any disease under such conditions must be difficult We must bear in mind that the diagnosis on neoplasms on the surface of the body in their early stages presents considerable difficulty, and in the case of the stomach we are required to diagnose these new growths in an organ entirely hidden from view and almost entirely from touch With a knowledge of the nature and cause of the disease will come a knowledge of its early recognition and its successful treatment Think of the condition of the diagnosis of diphtheria and tuberculosis before the cause of these diseases was understood But from many sides and in many countries dutiful labourers are working towards the common goal of the cause of this human scourge Then will come the time when the malignant neoplasm will melt away under the influence of a new treatment similarly as the pseudo membrane disappears in diphtheria after the injection of antitoxin There is some reason to believe that not all malignant neoplasms have the same etiology and therefore will probably not have the same treatment Recent personal studies have led me to incline to the view that in some carcinomas, at least, we are dealing with a deep-seated disturbance of the *innermost metabolism of the individual* cells, and that whatever bacteriological findings can be made in such growths are of secondary importance or accidental accompaniments The further development of the subject depends, in my opinion not so much on bacteriological investigation as upon the pathological and physiological chemistry of the cell, though the problem as yet presents great difficulties, still, they do not seem insurmountable even with the means at present at the disposal of the physiological chemist

The inevitable recurrence of carcinoma after operation of gastric malignant neoplasm should impress us with the fact that surgical operation cannot be the treatment of the future for such diseases The impression is spreading that gastric surgery can, after all only bring symptomatic relief, and according to the classical testimony of Mikulicz[40] gastric surgery, after a career boldly and brilliantly begun, has arrived at the height of its capability for technical development after 20 years and now stands arrested before the natural boundaries of internal medicine the fundamental pillars of pathology It does not appeal to reason *to* assume that this form of treatment by operation merely, although it is at present the most satisfactory and promising that we possess, represents the limit of human knowledge and ingenuity The Loffler Behring Pasteur, Koch, and Virchow of the future will solve this riddle for us and the obscurity about malignant neoplasms must vanish before human intellect and then will come an effective treatment based upon the etiology of the disease "Life is short, but Art is long Hippocrates *Ο μὲν βίοι βραχυς η δὲ τέχνη μακρὰ*

[40] Chirurgischer Congress 1901

A Clinical Lecture

ON

SYPHILITIC AFFECTIONS OF THE STOMACH.

Delivered at the London Temperance Hospital

BY W SOLTAU FENWICK MD, M R C P LOND,

SENIOR PHYSICIAN TO THE HOSPITAL PHYSICIAN TO THE EVELINA HOSPITAL FOR SICK CHILDREN

GENTLEMEN During the last few months you have had the opportunity of observing several cases in which instead of adopting the orthodox methods of treatment for ulcer of the stomach or gastritis we employed large doses of iodide of potassium and other anti syphilitic remedies with immediate and complete success The curious toleration displayed by these patients to drugs which under ordinary circumstances aggravate rather than relieve the symptoms of gastric irritability helped at the time to confirm our suspicions concerning the specific origin of the diseases in question, and will now serve me as an excuse to draw your attention to a subject of great practical importance, but one which is hardly mentioned even in the most recent English text books

It is commonly taught that while both the mouth and the rectum frequently suffer from tertiary manifestations of syphilis, the intermediate portions of the alimentary canal habitually escape and even the cases of gummatous lesions of the stomach described many years ago by Cornil, Klebs and Birch Hirschfeld have apparently failed to shake this belief The conservatism thus displayed is not due entirely to that strange pertinacity which causes each successive author to reproduce the time worn arguments and statistics of his predecessors but also in great measure *to the* injudicious zeal of certain writers who, having been imbued with the notion that in a syphilitic subject all diseases are syphilitic, too often neglect demonstrable facts in favour of unwarrantable assumptions. I therefore propose to confine my observations to such morbid conditions of the stomach as have been proved to result from syphilis, and only to draw such conclusions from them as clinical observation can substantiate.

Syphilis may affect the stomach in three ways: (1) by the formation of gummata; (2) by the production of endarteritis; and (3) by exciting chronic inflammation of its mucous membrane.

1. *Gummata.*—A gumma of sufficient size to attract attention is rarely encountered. Chiari only observed three instances in 243 necropsies upon persons suffering from syphilis and in all about 16 genuine examples are recorded in the literature of the subject. The tumour, which is often multiple, is usually situated in the submucous tissue of the pyloric region near the lesser curvature. It is round or somewhat flat, yellowish in colour, firm on section, and varies from 10 to seven centimetres or more in diameter. At first the mucous membrane which covers it is stretched and thinned out from pressure, but as the nodule increases in size and its substance undergoes softening it usually becomes destroyed and an ulcer is produced. A gummatous ulcer consequently presents certain features which serve to distinguish it from the simple variety. In shape it is often irregular, scalloped, or even triangular, its edges are thickened and undermined, while its walls and base are shaggy, cheesy, hæmorrhagic, or covered with a firmly-adherent yellow slough. The mucous membrane in the vicinity of the neoplasm or its resultant ulcer exhibits signs of chronic inflammation and is not infrequently studded with minute gummata. Perforation of the stomach has not been observed, although in a case recorded by Lancereaux this accident was only prevented by the presence of a cheesy nodule. It is important to observe that in all these cases manifestations of syphilis were present in the other abdominal viscera, the liver, pancreas, spleen, or lymphatic glands presenting gummata or cicatrices. In cases of congenital syphilis in newly-born infants the small intestine is particularly apt to suffer and small gummata may often be found scattered throughout its length or congregated about the ileo-cæcal valve. Similar conditions have also been described in the fœtus (Bittner).

2. *Endarteritis.*—Obliterative endarteritis affecting the gastric vessels must not be regarded as necessarily an indication of syphilis. It may be observed in the fibrous base of nearly every chronic simple ulcer and in not a few cases of long-standing perigastris due to disease of some neighbouring organ. Its pathology is similar to that form of the endarteritis which commonly accompanies cirrhosis of the lung and kidney, and in the case of a gastric ulcer its existence is of some value to the organism since the gradual occlusion of the arteries which lie in the track of the advancing disease tends to prevent hæmorrhage. The syphilitic variety, on the other hand, is comparatively rare as a primary complaint, and as far as my own experience goes is always associated with gummata in the liver, spleen, pancreas, or retro-peritoneal glands. It chiefly affects the smaller branches of the pyloric vessels which ramify in the subserous and submucous connective tissue, and by thus diminishing the blood-supply to the part tends to induce inflammatory thickening of the mucous membrane and to give rise to interstitial hæmorrhages and superficial ulcerations. When the process is especially severe or widely diffused the nutrition of the gastric wall is so much reduced that the tissues are no longer capable of withstanding the solvent action of the gastric secretion, which consequently erodes the surface and gradually produces an indolent form of ulceration. In other cases the partially obstructed vessel becomes the seat of thrombosis and the mucous membrane which it supplies, being suddenly deprived of blood, is rapidly digested. In the former case the patient suffers from the symptoms of chronic ulcer of the stomach; in the latter from attacks of acute dyspepsia which are not infrequently followed by hæmatemesis.

3. *Chronic gastritis.*—This may ensue either as a direct or as an indirect result of syphilis. The latter variety is by far the most common and is due either to embarrassment of the gastric circulation from disease of the liver or spleen, to lardaceous degeneration of the vessels of the stomach, to secondary disease of the kidneys, or to the specific cachexia. This gastritis does not differ histologically from the usual forms and like them usually subsides when its exciting cause has been removed. Chronic inflammation of the stomach *directly* dependent upon the systemic infection occasionally results from repeated acute attacks during the early phases of the complaint, such as have been described by Jullien and Fournier, but as a rule it only appears at an advanced stage of the disease and is often associated with gummatous lesions of the bones, liver, or testes. To the naked eye the mucous membrane is either dull white and peculiarly opaque, or appears to be thickened and irregularly congested, with a surface like velvet pile. On microscopical examination the superficial roughness of the tissue is found to be due to an absence of the normal columnar epithelium and to a hyperplasia of the connective tissue between the mouths of the glands which give the section the appearance of being connected with fine papillæ. The capillary vessels which ramify between the glands are dilated and filled with blood corpuscles, but here and there their outlines are obscured by an accumulation of small round cells which pervade the whole of the connective tissue and form thick layers around the mouths and fundi of the glands. The lymphoid follicles are enormously enlarged and their cellular elements frequently penetrate the muscularis mucosæ and invade the submucosa. The gastric glands vary in appearance at different parts of the section, at one spot being comparatively healthy, while at another they are twisted, distorted, or disorganised by the round-cell infiltration. These general features are common to all forms of interstitial gastritis, from whatever cause they arise, but in the present case two special phenomena exist which indicate the syphilitic origin of the disease. The first of these takes the form of miliary granulations which occupy the whole thickness of the mucosa and may even invade the submucous tissue or project slightly above the free surface. These nodules, which are really minute gummata, consist for the most part of a homogeneous, granular, non-staining material, and where several have coalesced a large portion of the section appears to consist entirely of this cheesy material. The other characteristic feature of a syphilitic gastritis is a hyperplasia of the inner coats of the small arterioles situated in the submucosa which produces considerable narrowing of their lumina and not infrequently leads to thrombosis. These arterial changes may be observed in any part of the section but are always most noticeable in the vicinity of the miliary gummata.

Before proceeding to describe the clinical aspect of these diseases there are two errors against which I must caution you. In the first place, do not run away with the idea that every gastric ulcer is due to syphilis simply because the patient happens to have suffered at some time or other from that complaint. It should always be borne in mind that probably about 5 per cent. of the population suffer from ulcer at some period of their existence, and since syphilis is also by no means uncommon it must necessarily happen that the two diseases will frequently be associated in the same individual independently of any causal relationship between them. In 308 cases of chronic gastric ulcer of which I possess clinical notes a history of former syphilis existed in 10 per cent., but in the 132 fatal cases of the disease gummata or other evidences of syphilis were observed after death only in eight, or about 6 per cent. I am therefore of opinion that only about 5 per cent. of all chronic ulcers of the stomach have any direct connexion with syphilis, and that in the majority of these the connecting-link is to be found in arterial degeneration rather than in the formation of gummata.

My second warning is this: before you conclude that the symptoms of gastric irritation in a syphilitic subject are due to the specific malady make quite sure that they do not arise from injudicious medication. You are aware that many persons are very intolerant both of mercury and potassium iodide, and that the prolonged administration of these drugs frequently gives rise to troublesome gastritis, accompanied by anæmia, loss of appetite, emaciation, and great debility. When these symptoms develop in a patient who has been under our care from the first there is, of course, no difficulty in assigning the gastric disorder to its proper cause and, by discontinuing the line of treatment, in curing it. When, however, a patient of whom we know nothing except that he has had syphilis consults us for chronic gastritis there is always a great temptation to overlook the possibility of toxic influences and to prescribe the same drugs which were originally responsible for the disease. Some of you may recollect a good instance of this in the case of a woman who was sent to us with a diagnosis of cancer of the stomach on account of the pain after food, vomiting and loss of flesh from which she had suffered for several months. You will remember we found upon inquiry that she had been under medical treatment for some time for an ulcer of the leg and was inclined to attribute her indigestion to the pain and worry attendant upon that disease. As, however, she was obviously suffering from a gastritis of toxic origin we preferred to take the view that the medicine and not the sore *on the leg was the cause of the trouble, the assumption* being that the former treatment had been directed against possible syphilis. Careful regulation of diet combined with a rhubarb and bismuth mixture afforded immediate relief and within a month the patient reported herself as feeling perfectly well. It therefore behoves us to remember that gastritis occurring during the course of syphilis may result from injudicious treatment as well as from the disease itself.

Chronic ulceration of the stomach due to syphilis is most common in men between 25 and 40 years of age, in many of whom secondary symptoms of the infective disorder have either been very slight or were rapidly removed by treatment. The gastric complaint usually develops slowly and for several months may be mistaken for some form of simple or inflammatory dyspepsia, but sooner or later the characteristic symptoms of ulcer show themselves and soon become severe. So far as my own experience goes—and I am unfortunately obliged to quote it owing to the absence of clinical literature—these cases chiefly differ from the simple variety of the disease in three particulars, the first of which is the extreme severity of the pain and vomiting, the second the infrequency of hæmorrhage, and the third their obstinacy to ordinary treatment and tendency to relapse.

Pain is invariably present, and as is usual in gastric ulcer is principally experienced in the epigastrium within half an hour after a meal containing solid food. In many instances, however, the suffering is almost constant and even a diet of milk gives rise to oppression at the chest with distension and troublesome flatulence. When the disease has existed for some months the pain is often most intense during the night when the stomach is devoid of food, and it may then extend all over the abdomen and chest and radiate down the extremities or up the neck. Under these conditions the epigastrium is usually very tender, and the cranium, the tibiæ, and the heels may also be unduly sensitive to pressure. The attacks last for several hours and are frequently accompanied by flatulent and acid eructations, burning in the throat, intense thirst, and vomiting. They are temporarily relieved by a draught of milk or a dose of bicarbonate of sodium and more effectually by vomiting. Rosanow diagnosed a syphilitic ulcer in a patient on account of the nocturnal pain and successfully treated it, while Bartumeus appears to lay stress upon attacks of emesis during the night, but since both these phenomena are met with in simple ulcer when complicated with hypersecretion they cannot be regarded as pathognomonic of the specific form of the complaint. Vomiting is another conspicuous feature of the disease. At first the patient may only be sick during the painful crisis which the act of emesis tends to curtail, but as soon as secondary gastritis develops vomiting may occur after every meal, while from time to time attacks come on which last for many days and prevent the administration *of nourishment by the mouth.* The constant pain and vomiting soon induce a serious deterioration of the general health. The patient becomes very thin and feeble and presents the pinched and careworn look of one who is always suffering. The appetite may remain good or even be excessive, but he is afraid to gratify the desire for food on account of the punishment which is sure to follow, while at intervals he is tormented by a thirst which no amount of water will subdue. The bowels are confined and the tongue is often covered with a white fur. The urine is diminished in amount and its reaction is often neutral or slightly alkaline, while in many cases it contains an excess of phosphates but is deficient in chlorides. Anæmia is invariably present and the peculiar sallow complexion of many of the patients is very suggestive of specific cachexia. Although nearly 70 per cent. of the cases of simple ulcer suffer from hæmatemesis this symptom appears to be comparatively rare in the syphilitic disease, possibly on account of the gradual obliteration of the gastric vessels which, as I have already pointed out, occurs in the vicinity of the sore. When, how*ever, the portal circulation is embarrassed by coexisting* disease of the liver or spleen vomiting of blood may be an early and recurrent symptom.

As a rule the complaint fails to respond to the ordinary methods of treatment, and even when anti-syphilitic remedies are employed it may exhibit a great tendency to relapse. This latter peculiarity was very marked in the case of a woman who came under my care four or five times within two years for severe pain and vomiting after meals, accompanied by rapid emaciation. On each occasion the administration of mercury and iodides afforded almost immediate relief and the disease appeared to be cured at the end of two months, but as soon as she discontinued the medicine, though persevering with a liquid diet, the pain [illegible] vomited her food [illegible] f digestion I have very [illegible] stages of the complaint free hydrochloric acid may usually be detected after a test meal, and in those cases where nocturnal attacks of pain are present the vomit usually contains an excess of the mineral acid. But when the disease has given rise to great loss of flesh and to debility I have never observed hyperchlorhydria, but on the contrary have usually found evidence of lactic acid fermentation. When vomiting is excessive the ejecta consist almost entirely of alkaline and bile-stained mucus. The usual cause *of death is exhaustion from inanition*, but an intercurrent affection like tuberculosis or some syphilitic complication often hastens the fatal termination. Hæmatemesis and perforation appear to be rare. Among the sequelæ of the disease pyloric stenosis is the most important, as has been recorded by Cornil, Wagner, and Klebs.

Gastritis occurs both in hereditary and acquired syphilis and is chiefly characterised by its chronicity and intractability to ordinary treatment. In infancy and early childhood the intestine usually suffers along with the stomach, so that in addition to the vomiting there is either diarrhœa or obstinate constipation. In all cases the loss of flesh, anæmia, and debility are out of all proportion to the severity *of the local symptoms owing to the consecutive* atrophy of the gastric and intestinal glands which can be demonstrated in almost every case of so-called "syphilitic marasmus." During the period of childhood intercurrent attacks of acute gastritis, characterised by incessant nausea and vomiting and occasionally by severe gastralgia, are apt to occur from time to time. The bowels are confined, the tongue is thickly [illegible] appear at night. If no food c[illegible] the disease may prove fatal, bu[illegible] passes off in a few days and is again replaced by the chronic form. In almost every instance the child presents evidences of syphilis in the face, teeth, and eyes, while not infrequently the development of a gumma heralds the onset of an acute attack. In a case which I have often shown in this hospital a large mass could be felt for several months in the liver and subsequently a gummatous swelling appeared upon the forehead, while in the one reported by Heimmeter the child presented an enormous gumma of the lower jaw.

Mild forms of gastritis occurring in adult life are practically indistinguishable from the alcoholic variety, but in the more severe cases the progressive loss of flesh, excessive debility, anorexia, and profound anæmia, coupled with the absence of free hydrochloric acid from the gastric contents, are highly suggestive of a malignant growth. More than one case of this description has come under my care in which, if it had not been for a routine trial of iodide of potassium, I should have diagnosed cancer of the stomach, and I have known several patients who were condemned to carcinoma of the stomach or pancreas after an exploratory incision who made a perfect recovery under anti-syphilitic treatment. Although traces of altered blood may appear in the vomit, severe hæmatemesis is rarely observed unless the liver or spleen is also diseased.

DIAGNOSIS.

Specific ulceration of the stomach has to be distinguished clinically from the simple variety, from cancer, and from the gastric crises of locomotor ataxia. In every case of gastric ulcer the possibility of former syphilis should be borne in mind, and a careful search should be made for scars and other evidences of the disease. [illegible] severe pain and vomiting with great emaciation or profound anæmia are always suspicious symptoms, while nocturnal attacks in which pain is felt in the long bones as well as in the abdomen are most suggestive of syphilis. The [illegible] chief point of distinction, however, is the intractability of the disease to ordinary methods of treatment, while its symptoms rapidly subside on the administration of anti-syphilitic remedies. More than 60 years ago Andral diagnosed a syphilitic ulcer of the stomach from the fact that it was cured by mercury, and Galliard, Lancereaux, Wagner, Hayem, Rosanow, and Maic have all recorded instances in which the nature of the complaint was manifested in a similar manner.

The differential diagnosis of specific ulcer and cancer is often very difficult, especially when the former is accompanied by severe gastritis. In malignant disease, however, a tumour can usually be detected in connexion with the stomach: the loss of flesh and strength are more rapid, nocturnal attacks of pain are infrequent, and the vomit often contains altered blood. The subjects of gastric cancer are also very intolerant of mercury and iodides and after a few days' treatment will usually volunteer the statement that the medicine is making them much worse. In the syphilitic affection, on the other hand, these remedies are the only ones which are found to afford relief. The gastric crises of locomotor ataxia occur at irregular intervals and are seldom excited by the ingestion of food. There is little or no localised tenderness of the epigastrium and the patient presents the usual signs of early tabes. It is important to remember that the gastric disease and the specific lesion of the central nervous system seldom, if ever, coexist.

The diagnosis of syphilitic gastritis is made by the absence of the usual conditions which excite inflammation of the stomach and by the discovery of a strong history or of objective evidences of syphilis. A few days' trial of iodide of potassium will usually clear up any doubt, since in ordinary cases of gastritis this drug greatly increases the dyspeptic symptoms, while the contrary result is observed in the specific disorder.

TREATMENT.

Absolute rest is essential, and much time will be saved if the patient is confined to bed for the first fortnight. Milk should form the staple diet for the first three or four weeks, but as it does not always agree so well as in simple ulcer it may be necessary to administer it diluted with soda water or Vichy water. When vomiting is a troublesome symptom the milk should be peptonised. Clear soups and broths and jellies and junket may also be allowed if they can be taken without discomfort. After the first month, should the case be progressing favourably, milk puddings, soft bread-and-butter, eggs, tripe, and oysters may be allowed, and the diet may subsequently be increased by the addition of pounded fish, finely-minced sweetbreads, and chicken cream. Meat and green vegetables should not be allowed for at least six months. If vomiting is urgent it may be necessary to feed the patient by the rectum. When abdominal pain is severe the epigastrium may be constantly covered with a large linseed poultice, but as a rule the repeated application of small blisters is of greatest value. With regard to medicinal treatment it may be stated at once that mercury should always be combined with the iodides, since the latter are much less efficacious when given alone. In most instances it is sufficient to prescribe a mercurial pill of two grains with an equal quantity of extract of hyoscyamus night and morning, but occasionally drachm doses of the solution of perchloride of mercury are to be preferred. In young children inunctions of mercurial ointment or full doses of mercury and chalk are the most convenient method of administering the drug. If there is any tendency to diarrhœa a small quantity of opium may be included in the prescription. The iodide of potassium must be given in doses of from five to 15 grains, and is conveniently combined with carbonate of bismuth and liquid extract of sarsaparilla, while the addition of 10 minims of glycerine of carbolic acid often helps to prevent the oppression and flatulence experienced after food. Should the bowels remain constipated in spite of the mercury a teaspoonful or more of Carlsbad salts may be given each morning before breakfast. Lavage is chiefly indicated in chronic gastritis accompanied by troublesome vomiting and in cases of partial obstruction of the pylorus; but it must be avoided when the symptoms of ulceration are present. In every instance the patient should be warned of the possibility of a relapse lest he be tempted to discontinue the treatment as soon as the urgent symptoms have subsided.

VACCINATION STATISTICS.—At a meeting of the Bath Board of Guardians held on Sept. 18th it was reported that during 1900 there were 1668 births registered and that of these children 1071 were successfully vaccinated. 40 summonses for non-vaccination were obtained, of which 18 resulted in the defendants being fined, the remaining 22 being eventually vaccinated.

THE INFECTIOUSNESS OF THE MILK OF TUBERCULOUS COWS; THE BACTERIOLOGICAL DIAGNOSIS, AND THE PRACTICAL VALUE OF TUBERCULIN FOR THE EXTERMINATION OF TUBERCULOSIS AMONG CATTLE.[1]

BY DR. LYDIA RABINOWITSCH,
OF THE INSTITUT FÜR INFEKTIONSKRANKHEITEN, BERLIN.

THE frequency and constant increase of tuberculous disease among cattle long ago drew serious attention to the question whether the milk of tuberculous cows is capable of carrying infection to other animals. By means of minute and varied experiments it has been established beyond doubt that such is indeed the case—that tuberculosis can certainly be produced in calves and swine through feeding them with infected milk. Nevertheless, it still remained to be shown how very common this mode of infection is under natural conditions. The magnitude of this danger of the spreading of tuberculosis among animals due to the consumption of milk is best illustrated by the frequent occurrence of tuberculosis among calves and by the alarming increase of the same disease among swine which has been observed within the last few years. About 90 per cent. of the latter cases have been proved to originate in feeding with infected milk. The frequent occurrence of intestinal infection need not be wondered at when we consider the extent of tuberculous disease among milch cows as well as the fact that for a considerable length of time after birth the young calves are almost exclusively fed with their mothers' milk. The increase of tuberculosis among swine is further explained by the fact that the farrows are likewise raised on cows' milk, the principal fodder of pigs in these days of large dairies consisting in the raw dairy residues made up of the deposits and the skim milk left over from the centrifuging process. The transmission of tuberculosis among cattle and pigs by means of milk being established, it now remains to be seen whether the milk of all tuberculous cows contains tubercle bacilli, or whether the infectious properties are confined to special forms of tuberculous disease.

The investigations of Bollinger, Bang, and a great number of other observers many years ago established that the milk of cows suffering either from general tuberculosis or from tuberculosis of the udder contains tubercle bacilli. A few observers, such as Hirschberger and others, have experimentally demonstrated the infectious quality of milk derived from cows with incipient tuberculosis and non-tuberculous udders. Since the important discovery of tuberculin, however, there has been no examination into the question as to whether tubercle bacilli may not be present in the milk of animals which do not show any clinical signs of tuberculosis but which nevertheless are shown by their susceptibility to the tuberculin test to be tuberculous. A positive answer to this question was furnished in 1899 by the joint investigations of myself and Dr. Kempner. We found that tubercle bacilli may be present in the milk in cases of tuberculosis, latent, but revealed by the tuberculin test. If, then, the milk of such cows contains tubercle bacilli, it must needs be regarded as infectious, and such milk must be held no less dangerous for the consumption of young animals than that of milk from cows with advanced general disease or with diseased udders. In these as well as in my subsequent experiments I tested the presence of tubercle bacilli in the milk by means of intra-peritoneal injection in guinea-pigs, as I consider this method to be not merely satisfactory, but indeed the only safe method. The alternative way to prove the infectious character of milk by feeding animals with it is unreliable, since the quantity of tubercle bacilli thus introduced in the course of one experiment or of several experiments is greatly inferior to the amount which the animals would actually consume within a given period of time as part of their food. In the long run even a very slightly infectious kind of milk is bound to produce the disease.

---

[1] A paper communicated to the British Congress on Tuberculosis, Section III., Pathology, including Bacteriology.

The presence of tubercle bacilli in the milk of cows that respond to the tuberculin test without showing clinical evidence of tuberculosis was proved in the same year by Ostertag in regard to mixed milk and by Adami and Martin in regard to the milk of a number of individual cows. A further proof in support of this theory was furnished by my observations last year on milk supplied to infants in Berlin. I found no tubercle bacilli in the milk taken from cows which had been regularly subjected to the tuberculin test, while the supply obtained from animals not subjected to this test contained tubercle bacilli though they showed no clinical symptoms of tuberculosis. My own bacteriological observations of former years, as well as the more recent investigations chiefly concerning the milk of cows with suspected tuberculosis of the udder, established the following facts:—

The detection of tubercle bacilli by means of microscopical examination of specimens of cream and sediment from centrifuged milk is unreliable, because the absence of acid-resisting bacilli from the specimens examined cannot be considered convincing as their number may be so small as not to be found on every slide examined under the microscope, whilst even a very small number of tubercle bacilli can be detected by animal experiment. Besides, in milk there occur bacteria which with regard to their growth, as well as to the effect which they have on the animal organs, are very similar to the acid-resisting bacilli which were found by Koch in butter, and which under the microscope are unfortunately very difficult to distinguish from tubercle bacilli. These bacilli were not only found by Petri, Beck, Santoni, myself, and others in the ordinary market milk, but we were also able to detect and to isolate them by animal experiments from specimens of milk obtained under aseptic conditions from individual cows. The above-mentioned discovery of the acid-resisting bacilli, so similar in their nature and appearance to tubercle bacilli, in the milk of cows suspected of tuberculous disease made by our observations some years ago has been recently confirmed by the experiments of Kühnau. This investigator was able both in specimens of mixed milk and also in milk taken under aseptic conditions from individual cows, to prove by animal experiment the presence of these bacilli in from 20 per cent. to 25 per cent. of the cases examined. Whether these bacilli are secreted by the mammary glands or whether they enter the milk ducts of the frequently inflamed udders from without is still uncertain, and for the differential diagnosis of these bacteria is without importance. In the light of recent investigations we certainly need not be surprised to find these bacilli in the milk. Several years ago Severin found the same kind of bacteria in cow dung while Olt demonstrated their presence in the contents of the intestine of tuberculous as well as of healthy cattle. Moëller further succeeded in obtaining isolated cultures of these acid-resisting bacteria from the cow dung as well as from the timothy grass used as fodder. The same kind of acid-resisting bacteria, or similar ones, have been recently detected by Cowie on the udder, and by Ludwig Neufeld in the mammary gland, of the cow. Besides these acid-resisting bacteria Nocard and Mollereau, Bang, and others detected, some years ago, saprophytic as well as pathogenic bacteria, especially streptococci, in the udder of cows suffering from mastitis. These discoveries were recently confirmed by the experiments of Ward, as well as by those of Reed and Ward. The last named observers have even isolated streptococci along with harmless bacteria from the milk of cows which were apparently healthy, showing clinically no signs of mastitis. When the udders of the slaughtered animals were examined streptococci of the same kind were found to be present in all parts of them. The other bacteria too, which were found in the udder after the cow was slaughtered proved identical with those previously isolated from the milk. That streptococci may be present in the milk a long time after the mastitis has disappeared has recently been proved by the experiments of Lameris and van Harrevelt.

In view of these facts the presence in cows' milk of the bacteria which resemble tubercle bacilli is, after all, not difficult to explain, as these microbes, as well as streptococci, can either enter the udder from the outer world through the teat, or they can be taken in with the food and absorbed by the blood and lymph stream from the intestinal canal and carried thence to the udder. In the present state of our knowledge it is not yet certain whether these bacteria can be the cause of the mastitis, or whether, the mastitis already existing, the inflamed tissue merely furnishes a suitable nourishing medi[illegible] these acid-resisti[illegible] in a specimen of [illegible] tion of these from the genuine tubercle bacilli, especially when both kinds are present mixed in one and the same specimen of milk, is rendered extremely difficult or even impossible.

The only reliable method of proving the presence of tubercle bacilli in milk which remains is therefore, animal experiment—namely, the intra-peritoneal injection into guinea-pigs of a mixture of the cream and sediment of thoroughly centrifuged milk. The following interesting experiment made by Ostertag shows how very susceptible the guinea-pig is when subjected to intra-peritoneal inoculation. The milk of a cow with a tuberculous udder, 20 cubic centimetres of which being given to a guinea-pig by the mouth produced intestinal tuberculosis, was able to produce general tuberculosis when injected into the peritoneal cavity of guinea-pigs even after it had been diluted 100 000 times. By comparative experiments I was, indeed, able to prove that the last milk obtainable from the udders of suspected cows gave positive results in regard to the presence of bacilli whilst the first milk obtained from the full udders was not able to convey tuberculous infection in the animals. It must further be noted that it is necessary to examine the suspected milk repeatedly and at various times, as a single negative result cannot be considered finally convincing. Although it is easy to prove the presence of a small number of tubercle bacilli by means of inoculation the result of the experiments may be obscured where changes resembling tubercles are seen in the tissues when examined with the naked eye but which in reality have been caused by the action of the above-mentioned acid-resisting bacilli. Their pseudo-tuberculous nature can easily be proved when examined under the microscope. But, as we have already seen, real tubercle bacilli may be found in the tissues along with the acid-resisting bacilli; it is therefore advisable to carry on, in addition to a histological examination, inoculation experiments with parts of the suspected tissue until positive results are obtained. Thus the process of diagnosing tubercle bacilli by means of experiments on animals may become very tedious and two or even three months may elapse before we are able to decide whether the milk of the cow suspected of tuberculosis really contains tubercle bacilli.

The presence of tubercle bacilli in the milk does not, as a rule, correspond to the extent of the disease in the animal as we have already had occasion to mention. It must be admitted though, that in cases of extensive general tuberculosis or tuberculosis of the udder the presence of tubercle bacilli in the milk may be expected. How very often the clinical diagnosis of tuberculosis of the udder meets with great difficulties, even in the hands of the most competent observers I had an opportunity to convince myself in the course of my last year's observations. The milk of the cows in question as well as the results of the clinical examination, were kindly placed at my disposal by Dr. Schütz, professor at the Veterinary School in Berlin, and Dr. Schroeder. I made it my task this time to carry on my experiments on the occurrence of tubercle bacilli in the milk only of such cows as have been proved by repeated clinical examinations to be suspicious or to show tuberculosis of the udder. These 10 cows, the milk of which was repeatedly examined microscopically and by animal experiment, have not been submitted to the tuberculin test. In experiments this year it has merely been wished to ascertain whether the clinical examination of a cow, especially of her udder, allows the inference that the milk of the animal is infectious. It would lead us too far to enter here into details of our experiments. I shall only mention the results of the examination of those cows which throw most light on the subject in question.

In one case where the clinical diagnosis pronounced the udder to be tuberculous the presence of tubercle bacilli was only detected by animal experiment, microscopical examination was negative. In another cow with the same diagnosis the microscopical examination of the milk repeatedly revealed a great number of acid-resisting bacilli while the animal experiment gave negative results. The necropsy of this cow did not confirm the clinical diagnosis of tuberculosis of the udder; it revealed merely the presence of chronic interstitial mastitis. Inoculation experiments with portions of the suspected udder also failed. In two other cows in one of which the diagnosis of tuberculosis of the udder was made with great certainty while in the other a strong suspicion was entertained, microscopical examination repeatedly detected in the milk a great number of acid-resisting bacteria of the nature of which we could not be sure. We thought them at times to be real tubercle bacilli; at other times they seemed more like rod-shaped bacilli merely resembling tubercle bacilli. Inoculation experiments with the milk of these two cows produced in the animals experimented upon suspicious changes which were due to acid-resisting bacilli resembling the tubercle bacilli. Further inoculation with suspected tissues of these animals gave a negative result. Of special interest was a case where the clinical diagnosis of tuberculosis of the udder was confirmed by the post-mortem examination. Neither the microscopical examination nor the experiments on animals could show the presence of tubercle bacilli in the milk. The microscopical examination of sections of the tuberculous udder revealed numerous clumps of tubercle bacilli in the tuberculous interstitial tissue, while there were none to be found in the milk ducts.

From a review of these cases we arrive at the conclusion that the clinical diagnosis of tuberculosis, especially of tuberculosis of the udder, does not enable us to judge whether tubercle bacilli are secreted with the milk of the affected cows. For, on the one hand, our previous investigations, as is seen in the account of the same, have shown tuberculous disease of the udder sometimes to escape detection altogether, or simple inflammation may be diagnosed clinically, while later the histological examination, as well as the results of inoculation experiments with the milk and with portions of udder tissue, prove that it was clearly a case of tuberculosis of the udder. Delépine arrived at the same result in the examination of a cow the udder of which was not found to be tuberculous till examined histologically. The milk of this cow contained tubercle bacilli, although repeated clinical examination as well as the observation of the udder with the naked eye after the necropsy yielded no grounds for suspicion of tuberculous disease. Of course, it is not to be wondered at that the commencement of disease of the udder escapes detection when palpation is used.

On the other hand, the udder may be clinically pronounced tuberculous while both the necropsy as well as the histological examination clearly show that we have merely to deal with a case of interstitial mastitis or of cyst formation in the udder. This fact was not only proved by Dr. Kempner and myself, as may be seen from the above synopsis, but the investigations of Adami and Martin, as well as those of Delépine, illustrated by a series of interesting experiments, led to the same results. Kühnau, in his recent paper on the Extermination of Tuberculosis among Cattle, has further shown that streptococci, which not infrequently invade the udder, as seen before, are occasionally capable of producing changes closely resembling tuberculosis. A third possibility has been also demonstrated in the present year by my own investigations, in which I proved that even repeated inoculation of the milk may fail to show the presence of tubercle bacilli, though the clinical diagnosis of tuberculosis of the udder was confirmed by the necropsy, and though great numbers of tubercle bacilli could be detected with the microscope in the tuberculous interstitial tissue though not in the milk ducts.

The presence or absence of tubercle bacilli in the milk of cows with tuberculosis of the udder is, in our opinion, greatly dependent on the extent of the disease in the organ. It is easy to understand that in a case where the tuberculous foci in the udder are circumscribed and encapsuled the tubercle bacilli will not be able to enter the milk ducts with the same case as they may do when the disease of the organ is diffused. From examination with the naked eye and under the microscope, as well as histologically, of a number of tuberculous udders which were kindly placed at my disposal by Dr. Reissmann, the director of the Berlin slaughter-houses, I was enabled to convince myself how very much the occurrence of tubercle bacilli in the milk depends on the extent and the local seat of the tuberculous changes in the udder tissue. In many cases of very advanced disease I was only able to detect the presence of tubercle bacilli in the fluid expressed from the milk ducts after having examined a great number of specimens. In several cases I failed to detect tubercle bacilli in the capillary milk ducts under the microscope, while in other cases the milk capillaries were crowded with bacilli. In view of the great variety of bacilli found in tuberculous udders, as seen in my investigations in this field, I venture to express a doubt whether the method (first recommended by Nocard) of harpooning does always furnish us with a sure means of judging whether in a doubtful case we are dealing with tuberculosis of the udder or not. Besides this the harpooning method has been pronounced recently by Kühnau to be not quite without danger to the animal.

So far we have seen that the clinical examination of milch cows as a means of inferring the presence of tubercle bacilli in the milk is, without the aid of auxiliary methods of research, both insufficient and unreliable. On the other hand, the method of demonstrating the presence of tubercle bacilli by means of experiments on animals may prove very tedious. There remains only the tuberculin test which is the sole quick and sure method. The tuberculin test is recommended by most of the distinguished authors along with the clinical examination as the best means of diagnosing and thus aiding the extermination of tuberculosis among cattle. It is, on the other hand, not difficult to understand that in view of the enormous spread of bovine tuberculosis the farmers should try to discredit tuberculin. But the great diagnostic value of tuberculin can scarcely be diminished by the fact that the failures in the diagnoses only amount to 2·9 per cent. (as Schütz proved) of all the cases subjected to this test. In cases where the diagnosis of tuberculosis has been made with great certainty by means of clinical examination the tuberculin test becomes naturally superfluous. This does away with the argument that about 10 per cent. of the cattle which fail to react to tuberculin nevertheless are tuberculous. These 10 per cent., as is well known, consist of highly tuberculous animals which have themselves produced and contain in their bodies so much tuberculin that they are unable to respond any longer to the tuberculin test: this argument is nevertheless brought forward again and again by the adversaries of our method. The tuberculin test should only be applied to animals which are suspected of tuberculosis, and when thus used failures in the diagnosis never occur, as I am informed by Nocard, who based his opinion on a prolonged experience in France. Bang, in his last year's treatise, also appears as a champion of tuberculin for diagnostic purposes; he still considers it to be the finest and safest means for diagnosing tuberculosis in animals in spite of the many opinions to the contrary.

We must point out the fact that the present scientific data with regard to the extermination of bovine tuberculosis clearly show this to be practically impossible without the aid of tuberculin. Naturally we must, in the first place, make a point of exterminating the cows affected with tuberculosis of the udder and general tuberculosis, since their milk is more than all other to be regarded as infectious. In the second place come the animals in which the clinical diagnosis can only be established by the help of tuberculin. These cows must first of all be separated from the healthy ones. The questions whether they should be killed and as to the proper time for doing so will depend on the quicker or slower progress of the tuberculous disease. That is to say, that of course not all the animals which react to tuberculin need be immediately slaughtered. We may therefore say that combined with the clinical and bacteriological examinations the tuberculin test furnishes us with the safest means of obtaining milk free from tubercle bacilli as well as of rearing cattle free from tuberculosis.

A CASE OF ACUTE DOUBLE PNEUMONIA TREATED WITH OXYGEN; RECOVERY.

By G. E. RICHMOND, B.A., B.Sc., M.B., B.S. LOND.,
OF THE IMPERIAL YEOMANRY HOSPITAL, PRETORIA.

THE treatment of pneumonia, like that of most acute fevers, is chiefly symptomatic and therefore more or less unsatisfactory. The great things expected of the anti-pneumococcic serum have scarcely been realised and one is sometimes tempted to think that the course of the disease has not been favourably altered by its administration.

According to Dr. Andrew Smith[1] of New York in pneumonia the cocci do not enter the substance of the lungs, but are contained in the air vesicles, as in a test tube, where they flourish and produce their toxins, which by absorption [illegible] the fever and prostration characteristic of the [illegible] e an acid reaction after [illegible] which by its accumulation in the air vesicles has been supposed to destroy the cocci and thus to bring about a sudden termination of the process. Now, it is well known that the pneumococci of Frænkel do not flourish in an atmosphere of pure oxygen, and [illegible] the administration of [illegible] pneumonia might pr[illegible] the lung which were still healthy and would probably be antagonistic to the growth of the cocci already present in the lungs.

---

[1] Twentieth Century Practice of Medicine, article "Pneumonia."

Some years ago an interesting case in point occurred in the Miriam Ward of Guy's Hospital under the care of Dr J F Goodhart, whose clinical assistant I was at the time. The patient was an old woman who was admitted for leucocythæmia, for which she was given inhalations of oxygen lasting 10 minutes three times a day. Suddenly she developed a high fever and definite signs of pneumonia consolidation appeared at the left base. Dr Goodhart examined the case and, agreeing with the diagnosis, gave a very bad prognosis, pointing out that pneumonia was often the closing scene of such a chronic disease. The inhalations were continued, and, to the surprise of everyone, the pneumonia rapidly cleared up in two days' time. The *only other treatment adopted was hot linseed poultices to* the left side. The particulars of the present case are as follows.

A man, 23 years of age, belonging to Kitchener's Fighting Scouts, was admitted to the Imperial Yeomanry Hospital at Pretoria on July 23rd, 1901, suffering from pneumonia. He had been ill for two days on the train coming from Durban and was somewhat collapsed on admission. His temperature was 101° F, his pulse was 120, and his respirations were 60 per minute. The abdomen was distended and tympanitic. The spleen was not enlarged. No typhoid spots were present. The tongue was covered with white fur. There were sordes on the lips and the patient was in a typhoidal state. A very troublesome cough was present, with expectoration of thick white sputum mixed with bright red blood. The man complained of pain in his chest on breathing or coughing but no friction rub was present. Breathing was rapid and laboured and at the rate of from 60 to 70 per minute. The slightest movement brought on a paroxysm of coughing which greatly exhausted the patient.

On examining the chest in front and in the axillæ and over the upper lobes behind there was harsh, loud, compensatory breathing, with absence of any adventitious sounds or bronchophony. Behind there was dulness of both bases up to the level of the ninth rib, and over this area there was bronchial breathing, with small consonating râles and bronchophony of cough sounds. *Above* the area of dulness on both sides the air did not enter well except in the upper lobes, where compensatory breathing was heard. The temperature rose to 103° at 10 P.M., but the patient was a little more comfortable.

The treatment consisted in the application of a pneumonia jacket and the administration of a mixture containing five minims of tincture of opium, four minims of liquor strychninæ, five minims of dilute hydrochloric acid, and one *ounce of peppermint water every four hours*, two ounces of brandy were also given daily. On the next day (July 24th) the signs of consolidation were extending upwards *pari passu* on both sides behind. In front the lungs were still quite clear. The temperature varied between 102° and 103·8°, the pulse was about 120 per minute, and the respirations were from 50 to 60. Dr H D Rolleston saw the patient in consultation with me and agreed with the suggestion that oxygen inhalations should be given to prevent if possible the spread of the infection to the upper lobes. These inhalations were ordered for 10 minutes every four hours on the morning of the 25th, and as there were no oxygen cylinders in the hospital nor in Pretoria the gas had to be prepared in a laboratory in the town and then brought up to the hospital in 40 litre gas holders. Great credit is due to Quartermaster Lieutenant Bruce, R.A.M.C., for the despatch with which he procured oxygen and kept up the needful supply of 40 litres daily for the inhalations. On the 25th the temperature was 104·6°, the pulse was 120 per minute and the respirations were 80. The oxygen inhalations were commenced on this morning and were continued until the 29th inclusive. The physical signs of consolidation (dulness, bronchial breathing and bronchophony, &c.) had extended upwards and the whole of the lower lobe on the left side and the lower and middle lobes *on the right side* were quite solid; the upper lobes remained quite free and compensatory breathing was heard all over their area. Examination was difficult as the slightest movement brought on a paroxysm of coughing and caused great exhaustion of the patient, his pulse and respirations becoming very rapid at these times. The respirations were from 90 to 110 per minute. There was a considerable amount of white frothy expectoration mixed with bright red blood and the cough was troublesome.

Dr Rolleston saw the patient with me again; we both thought that he would probably succumb to his disease and suggested giving four minims of liquor strychninæ and four minims of liquor atropinæ hypodermically twice a day instead of the above mixture. A special sister was detailed for the case and her assistance did much to bring about a favourable termination. The injection was given that night for the first time and was continued until the evening of July 29th. A mixture containing 15 minims of tincture of digitalis was ordered every four hours and the brandy was increased to four ounces daily. On the 26th the temperature was 103°, the pulse was 124 and the respirations were from 40 to 60 per minute. The patient was more comfortable, the cough was less troublesome, and he had a fairly good night but did not sleep much. There was no delirium. The back was not examined, but in both axillæ there were the physical signs of consolidation of the anterior bases of the lower lobes. The upper lobes remained free. The temperature fell slightly during the day and was only 101° at 4 P.M. No change was made in the treatment, oxygen still being given every four hours. On the 27th the patient was much more comfortable. The temperature fell from 101° at 4 A.M. to 98·6° at 8 P.M., the pulse rate from 138 to 86, and the respirations from 50 to 36. After this the patient made a good recovery, although he had an attack of pleurisy with acute pain in both axillæ necessitating the administration of one grain of morphia hypodermically and the application of blisters. Another attack of pain occurred over the left base on the 29th and over the right base on the 30th. A definite friction rub was heard in both axillæ and over the bases of both lungs behind, appearing first at the left base and then on the right side one day later. The man was now quite well with the exception of being debilitated.

On summing up the evidence for and against the value of oxygen as a prophylactic agent in the treatment of this case of pneumonia we find that there are certain points in favour of the patient quite apart from all considerations of treatment and other points of grave prognosis which perhaps under less favourable conditions might have brought about a fatal termination. The three chief points in this patient's favour were: (1) he was a young man (23 years of age); (2) his constitution was fairly robust; and (3) the degree of toxæmia was not of that severe type which is sometimes met with giving rise to temperatures ranging from 105° to 106° or more. The highest temperature charted was 104·6°. But when these points have been brought forward there is little else that can be said in favour of the patient himself being able to combat the attack.

The points against a favourable termination were: (1) the pneumonia was double, a point of grave import always; (2) the disease progressed *pari passu* on both sides until the upper lobes alone were left intact; and (3) the patient fell into a typhoidal state without delirium it is true, but with respirations of 80 per minute and a pulse varying from 120 to 136, and after the slightest exertion the respiratory rate was anything from 80 to 120 per minute. If this condition had lasted a day or two longer than it did the patient must, I consider, have died from lack of respiratory capacity, or if the upper lobes on either side had been attacked the subsequent dyspnœa must have killed him very shortly. From the time the oxygen was given the temperature began to fall, whilst before that it had been rising, the highest temperature (104·6°) being reached just before the first inhalation.

The difficulty of deciding whether it was the patient's own constitution or the benign influence of oxygen upon the course of the disease which brought about the successful termination is very apparent. But personally, I think that the administration of the oxygen prevented the spread of the infection to the upper lobes and probably brought about an earlier termination of the process than would otherwise have occurred. I [illegible] to have [illegible] respiratory and cardiac stimulant the hypodermic injection of strychnine and atropine was apparently of more service than administration by the mouth.

Pretoria.

A RÉSUMÉ OF MODERN VIEWS ON GASTRIC DIGESTION.

BY HENRY F. BELLAMY, M.D.

THE complex nature of the gastric mechanism renders the discovery of its inner workings a matter of ever-increasing toil to the experimental physiologist. To the medical man, unless his treatment is to be largely empirical and the results thereof uncertain, the need of a proper understanding and appreciation of the circumstances which control or influence the march of digestion in the normal stomach becomes each day more pressing. Fortunately, recent experience of the behaviour of the organ in health supplies him liberally with the means from which to form a rational basis for his therapeutical measures when called upon to remedy its distorted functions in disease. It is the purpose of the present article briefly to pass in review some important facts in connexion with this subject which have lately found light in the Lausanne laboratory.

Since the introduction by Pawlow of improved methods for accurately observing the phenomena of digestion on the living animal the physiology of the subject has made immense strides. The advance of knowledge has chiefly been in the direction of ascertaining how far the gastric function is influenced by the foodstuffs habitually ingested by the organism. Many years ago Schiff entered deeply into the subject of these influences, but, possessing no method of determining, even approximately, the amount of juice secreted under given conditions, his researches were necessarily restricted. For him there were but two possibilities—viz., either simple gastrostomy or infusions of the mucous membrane. The first proceeding enabled him to measure the power of the juice, as judged by the progress of digestion in the interior of the stomach; the second to measure the amount of pepsin to be found in the mucous membrane after the death of the animal. Nowadays, the classical operation of Pawlow affords a trustworthy method whereby the quantity and quality of the juice secreted under certain experimental conditions may be accurately estimated. As is well known, the operation consists in forming from the fundus of the stomach a diverticulum retaining its nerve-supply both from the vagus and sympathetic; its nerves being intact, this cul-de-sac works and rests in unison with the rest of the organ and furnishes a quantity of absolutely pure juice proportional to the extent of its surface. It is then possible, by digestions in vitro, to estimate the digestive capacity of juice received direct from the living animal.

Schiff's experiments and the conclusions derived by him therefrom are too well known to need recapitulation here. Those of the latter which more nearly concern our present subject may be summed up as follows. 1. That the gastric mucous membrane can, by a suitable and adequate meal, be entirely exhausted of its holding in pepsin. 2. That while certain "indifferent" foodstuffs exercise no influence whatever either upon the quantity or the quality of the juice secreted at the time of their ingestion there are others which possess in a marked degree the property of furthering the formation of pepsin. Among the 27 foodstuffs examined by him 12 proved themselves to be more or less positive in this respect; he accordingly termed them "pepsinogenes." They are as follows: (1) raw meat, (2) watery meat extract, (3) meat broth, (4) bone gelatin, (5) bread, (6) watery extract of bread, (7) dextrin, (8) certain peptones, (9) cheese, (10) watery extract of small peas, (11) watery extract of linseed, and (12) black coffee.

In contradistinction to these, the pepsin-forming substances, Pawlow's experiments on dogs have led him to the discovery of another class of substances possessing the property of calling forth the rapid and copious secretion of juice normally rich in acid, but producing no corresponding increase in the amount of pepsin; these substances are called by him juice-forming or "succagogues." Out of 16 foodstuffs examined the following eight were found to possess this property: (1) raw meat, (2) meat-juice. (3) broth, (4) meat extract (Liebig), (5) milk, (6) gelatin, (7) certain peptones, and (8) water (in large quantities).

Now, a comparison of this list with the preceding one reveals the striking fact that the majority of the substances described by Pawlow as "succagogues" are identical with those to which Schiff ascribed pepsinogenic properties. One would thus be led to suppose that these substances (or at any rate those of them which had been examined by both observers) were possessed of the double property, pepsin-forming and juice-secreting—or, in other words, that these two properties were identical. But a closer examination of the experiments of the respective observers brings to light the fact that these two classes of substances differ in one very important respect. Whereas the "pepsinogenes" of Schiff retain their action when absorbed from the rectum, the "succagogues" of Pawlow work only when brought into actual contact with the gastric mucous membrane, their action being entirely negative when administered per anum. It thus appears that the "pepsinogenes" exercise their influence through the agency of the blood and the "succagogues" through that of the nervous system.

It now occurred to Herzen that there might possibly exist substances possessing entirely or in great part the one or the other property. It so happened that Schiff had never experimented with Pawlow's most active "succagogue" (Liebig's extract), nor had Pawlow tested the "succagogic" properties of Schiff's principal "pepsinogene" (dextrin). With the object, therefore, of testing these two substances equally in both directions Herzen undertook a series of comparative experiments, of which the following may be considered typical. Pawlow's operation was performed upon a young, well-conditioned dog weighing 40 kilogrammes. The operation failed, however, in this respect—that in spite of every care the stomach fibres of the vagus appeared to have suffered injury. The possibility of this accident was suggested by the observations that the animal showed no trace of psychical reflex. As it happened, the absence of the latter was a distinct advantage, since its presence would have become a considerable hindrance to the determination of the possible secretory power of the "pepsinogenes"; indeed, it would have been necessary to counteract this disadvantage by an œsophagotomy, a proceeding demanding constant and elaborate care. The dog made a rapid recovery and the gastric cul-de-sac was found to carry out its functions satisfactorily.

It would be as well to diverge at this point from the account of the experiments performed on this animal in order to emphasise the importance of certain experimental conditions necessary to be fulfilled before the experiments themselves could be of any value. The holding in pepsin of the gastric mucous membrane at a given moment obviously depends upon the amount of pepsin formed by the previous digestion and how much of it has been secreted; in other words, on how much true pepsin (not propepsin) has remained over in the mucous membrane. If, then, the observer contents himself with merely taking the animal in a fasting condition, without regard to the quantity and quality of the last intake of food, he obtains, as chance may direct, a juice of less or greater activity. Since there may be pepsin remaining over from the previous digestion, by what method may the experimenter determine how much of the quantity present in the juice is newly formed as the result of the action of the substance experimented with, or even if this substance has in any way contributed to this new formation? The value of this quantity can only be accurately determined by ensuring the apeptic condition of the mucous membrane at the time of the experiment; this has been found to be the case when, from 14 to 18 hours before the experiment, a copious preparatory meal is given to the animal, the stomach being compelled in this manner to throw out the whole quantity of pepsin formed during the digestion of the meal. In order that its stomach might be in the apeptic condition in the morning, when the experimental meal was given and the juice collected, the Lausanne dog received its preparatory meal every evening between five and six o'clock. Some idea of its appetite may be gathered from the fact that the latter meal consisted, as a rule, of 1500 grammes of horseflesh boiled in water and given to the animal together with its broth and 3000 grammes of half-liquid polenta. The dog then received nothing except fresh water until between eight and nine o'clock on the following morning (16 hours after the preparatory meal) when the experimental meal was given. Now this latter meal had to be of such a nature that its main mass was composed of an "indifferent" substance—i.e., a substance the ingestion of which provoked the secretion of juice minimal in quantity and activity Both Schiff and Pawlow had been in the habit of employing for this purpose boiled meat washed out in running water, or coagulated albumin, after experimenting with various foods Herzen discovered an excellent material in polenta given in a half-liquid form. To this were added 50 grammes of the substance the properties of which it was desired to determine, when occasion demanded it the latter could also be administered per anum. The juice flowing from the gastric cul de sac was then received into a graduated vessel In the summer of 1900 over 100 experiments were carried out in this manner on the same dog The following are some of the more important results

1. *July 30th* —The preparatory meal was given on the previous evening at five o'clock. This morning at eight o'clock the experimental meal was given, consisting of polenta alone. The beginning of secretion was at nine o'clock 10 cubic centimetres of juice were collected at 10 o clock, the same digested 1 5 cubic centimetres of albumin The result was little juice and very little pepsin

2. *August 3rd* —The preparatory meal was given on the previous evening at five o'clock This morning at 8 30 the experimental meal, with the addition of 50 grammes of dextrin, was given The beginning of secretions was at 8 50 A M 10 cubic centimetres of juice were collected at 9 10 A M and 45 cubic centimetres at 10 50 A M Digestion of the first, 10 cubic centimetres and six cubic centimetres of albumin, that of the last, 10 cubic centimetres of albumin The result was very much more juice and considerably more pepsin

3 *August 4th* —The preparatory meal was given on the previous evening at five o'clock. This morning at nine o'clock the experimental meal, of polenta alone, was given The beginning of secretion was at 9 20 A M 10 cubic centimetres of juice were collected at 9 30 A M, when an enema of 50 grammes of dextrin in 200 grammes of water was given Further 25 cubic centimetres of juice were collected at noon The first 10 cubic centimetres digested 2 5 cubic centimetres of albumin the last 10 cubic centimetres digested 10 cubic centimetres of albumin The result was less juice than in the case of No 2, but still more pepsin

4 *August 15th* —The preparatory meal was given on the previous evening at five o clock. This morning at eight o'clock the experimental meal, with the addition of 35 grammes of Liebig's extract, was given The beginning of secretion was at 8 50 A M The first portion (10 cubic centimetres) of juice was collected at 9 15 A M At 11 o'clock a further 25 cubic centimetres had been collected The first 10 cubic centimetres digested three cubic centimetres of albumin, the last 10 cubic centimetres digested six cubic centimetres of albumin The result was a large quantity of juice containing a moderate holding of pepsin

5 *August 21st* —The preparatory meal was given on the previous evening at five o clock. This morning at 8 30 the experimental meal, of polenta alone, was given The beginning of secretion was at 8 45 A M Five cubic centimetres of juice were collected at 9 25 A M, when an enema of 20 grammes of Liebig's extract in 200 grammes of water was given At 11.25 A.M a further 10 cubic centimetres of juice were collected The first five cubic centimetres digested one cubic centimetre of albumin (10 cubic centimetres = two cubic centimetres of albumin), the last 10 cubic centimetres digested eight cubic centimetres of albumin. The result was little juice with rather high pepsin holding

It will be apparent from these five examples of Herzen's experiments that, when given in *large doses* by the mouth the meat extract and dextrin act both as "succagogues and "pepsinogenes'—i.e, that the copious ingestion of either of them suffices to produce the double effect of more juice and increased pepsin holding It is obvious, however, that the administration of a dose of Liebig's extract sufficient to ensure its action in both these directions would of itself give rise to pronounced digestive disturbances, and that instead of being assisted, digestion would quickly become deranged by this treatment A similar drawback attends the employment of large doses of dextrin, the disagreeable flavour of which soon becomes objectionable to the patient. In order, therefore, to avail himself successfully of this line of treatment the therapist must take advantage of a further remarkable fact brought to light by Herzen's experiments. It is found that, when given in *small doses* the pepsinogenic property of the meat extract and the secretory property of the dextrine tend to disappear, in other words, owing to the diminished force of their converse properties, the meat extract and the dextrin tend respectively to become a true "succagogue' and a true "pepsinogene" By prescribing, therefore, small doses of one or both of these substances the therapist may modify, according to the needs of his patient, the quantity and composition of the juice secreted

It has been mentioned earlier that the "succagogues" lose their secretory property when caused to be absorbed from the rectum A brief glance at Experiment No 3 in the foregoing series reveals a surprising fact in connexion with the administration of dextrin in this manner: it will there be seen that all influence in the direction of increased secretion of juice becomes lost the pepsinogenic property of the substance being alone retained

We have now to consider the question, Do there exist substances possessing *exclusively* the one or the other property? The latest work in the Lausanne laboratory points conclusively to a reply in the affirmative. Radzikowsky, Herzen's assistant, and Madame Mark Schnorf, one of his pupils have recently devoted their attention to this subject, the former has succeeded in discovering a true "succagogue' and the latter two "pepsinogenes The work of Radzikowsky has shown that ethyl alcohol is a pure juice expelling substance devoid of any trace of pepsin forming properties Experimenting in the manner above described, he finds that when the stomach has been thoroughly exhausted of its pepsin by a proper preparatory meal, the acid juice secreted by the action of alcohol is as good as pepsin free. The alcohol however, does not hinder the transformation of the propepsin into pepsin under the influence of a pepsinogenic substance, since when dextrin is at the same time caused to be absorbed from the rectum, the secretion of a juice rich in pepsin is obtained It is a remarkable fact that when administered per anum, alcohol also exercises a certain succagogic influence This action would appear to be an elective one on the gastric mucous membrane since unlike pilocarpine its administration causes no secretion from the other glandular structures of the body In ethyl alcohol we thus have an exception to the general rule above enunciated that juice-expelling substances work only through the agency of the nervous system, it is quite possible that further research will reveal others possessing a like property The results of Madame Mark Schnorf show that inulin and glycogen, carbohydrates closely allied to dextrine, even when given in large doses are pure pepsinogenes exhibiting no trace of secretory action. Another remarkable fact gleaned from the experiments of this observer is that the white so called pure dextrin exercises no influence whatever, either pepsin forming or juice expelling on the gastric mucous membrane these properties being entirely confined to the yellow dextrine of commerce

The practical importance of these researches may be estimated from the under mentioned examples representing the average variations in activity of the stomach under the conditions already discussed 1 After a meal consisting of 'indifferent' food stuffs such as boiled and washed out meat or coagulated albumin 10 cubic centimetres of juice may be secreted by the stomach in one hour, these 10 cubic centimetres will barely digest one cubic centimetre of albumin 2. After a similar meal to which has been added a juice-expelling substance 50 cubic centimetres of juice are secreted in one hour A portion of 10 cubic centimetres taken from this juice will digest one cubic centimetre of albumin, thus the whole hour's secretion digests five cubic centimetres instead of one cubic centimetre This is already a great advantage for the digestion 3 After a meal similar to No 1, to which has been added a pepsinogenic substance barely 10 cubic centimetres of juice are obtainable in one hour, but these 10 cubic centimetres digest say, six cubic centimetres of albumin This also is a great advantage for the digestion 4 Finally after a meal similar to No 1 to which has been added both a juice secreting and a pepsinogenic substance 50 cubic centimetres of juice can be collected in one hour of which each 10 cubic centimetres digests from five to six cubic centimetres of albumin—i e, in all from 25 to 30 cubic centimetres Here the advantage for the digestion is enormous, it being from 25 to 30 times stronger than in the first case and from four to five times stronger than in the second and third cases

These results tend to throw some light upon the fact that the juice furnished by a normal stomach is always in sufficient quantity and contains enough pepsin to bring about the digestion of an ordinary meal The majority of the foodstuffs contain secretory and pepsinogenic principles sufficient to call forth the secretion of a juice adequate for their digestion; those foodstuffs which do not initially do so nevertheless furnish them during digestion by virtue of the chemical changes which they undergo within the stomach. Natural feeding thus offers ample means for putting digestion in motion. Once started, its march becomes each moment more rapid until the culmen is reached when, owing to accumulation of its products, it begins to decline. There can be no doubt, however, that without unduly fatiguing the stomach its digestive capacity may be considerably raised by the ingestion of those principles the properties of which we have been considering. The importance of this fact becomes emphasised when dealing with the diseased or functionally inactive organ. Since their action is to raise the digestive capacity of the stomach two- or three-fold the administration of these substances becomes a therapeutical measure of immense value. It is not to be imagined that the clinical importance of their results remained unrecognised by Schiff and Herzen. Though their knowledge was limited to the power of the pepsin-forming substances yet they did not fail to realise the fact that in this class alone they possessed a potent means of control over the more commonly occurring forms of gastric derangement. Indeed, the favourable influence exercised on these cases by the "pepsinogenes" was repeatedly tested and confirmed by them. They found, for instance, that in obstinate cases of hyper-acidity almost immediate relief could be afforded by restoring the normal balance of acid and pepsin in the juice by the administration of a pepsin-forming substance. Thus, the excess of hydrochloric acid, formerly causing such distressing symptoms, was utilised for the benefit of the organism

The advantages in other directions of this control over the composition of the juice are so obvious that their recapitulation becomes almost superfluous. There seem, however, to be pathological or semi-pathological conditions in which this simple form of treatment becomes more especially indicated. An instance may be found in pyloric constriction where, on account of the suspension or deficiency of intestinal digestion, malnutrition forms a prominent and troublesome symptom. In these cases, by means of suitable stimulation, a large proportion of the work performed by the duodenum may be thrown upon the stomach and by this means the general nutrition may be correspondingly improved. Again, in the fatigued condition of the stomach during convalescence from acute diseases, when, in spite of the relative integrity of the digestive function, the work of the stomach is not carried out with sufficient energy to maintain the increased metabolism demanded by the enfeebled system, the organ may be stimulated to increased exertion and, by its initiative, may incite the other factors in the digestive cycle to renewed activity. Further, relief may be obtained in obstinate cases of infantile dyspepsia due to the interruption or perversion of natural means of nutrition, with consequent emaciation of the child; in a large percentage of such cases malnutrition is the result of a resort to artificial feeding. The treatment of the acute dyspepsia arising from this cause by the simple means of mixing broth with the child's milk has long been known as an empirical preventive measure; but its *rationale* becomes apparent only when it is known that meat broth, by virtue of its activity in the double sense of pepsin-forming and juice-secreting, has the property of promoting the rapid and copious secretion of a juice rich in pepsin.

The simple and even nourishing nature of the substances which may be employed to further the production either of juice or pepsin is a great consideration in favour of their use under the circumstances above enumerated. Nature is, so to speak, assisted through the agency of her own materials; food is necessary for the maintenance of life, and it should be the aim of the therapist to remedy the cause of disordered digestion through the natural channel offered by alimentation rather than by the more artificial, but in no wit more scientific, resources of pharmacodynamics. Further, owing to the facility attending the administration of these pepsinogenic substances per rectum the stomach does not become surcharged with materials which can be equally well absorbed elsewhere; by this means also the whole energy of the remedial agents is secured to the performance of its allotted task, no part of it being held back by the process of digestion. Personally I have seen nothing but good result from this line of treatment. The combination of dextrin and Liebig's extract or of dextrin and alcohol is especially to be recommended. The efficacy of dextrin alone in cases of insufficient production of pepsin is surprising and in no case has its administration been known to produce unpleasant results. A very large proportion of the knowledge derived from these researches should, however, be applied in avoiding harmful modes of nourishment in those cases where the cause of the trouble is already recognised by the medical man. It is perfectly obvious, for instance, that in cases of hyper-acidity no substance known to be "succagogue" should be ordered to be taken, since the symptoms of the patient would only be aggravated thereby. By the observance of rules such as this a rational line of treatment can be marked out to suit the requirements of almost any type of gastric disorder.

Lausanne.

A DILATED SUPERFICIAL ABDOMINAL VEIN WITH A SUGGESTIVE HISTORY.

By THEODORE FISHER, M.D., M.R.C.P. LOND.,

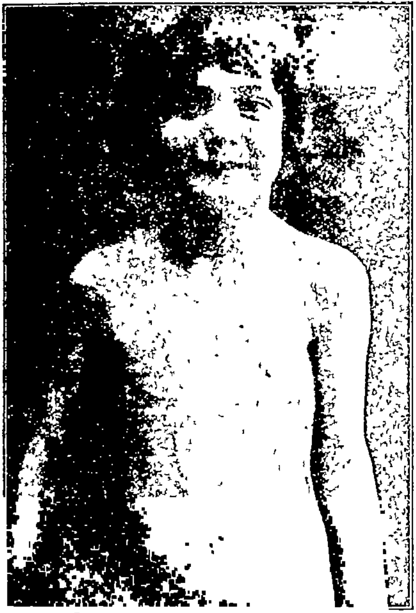
PHYSICIAN TO OUT-PATIENTS AT THE BRISTOL HOSPITAL FOR SICK CHILDREN; PATHOLOGIST TO THE BRISTOL ROYAL INFIRMARY.

THE accompanying illustration is reproduced from the photograph of a mentally deficient girl who attended the out-patient department of the Bristol Children's Hospital under my care. A large superficial vein was found running upwards over the right half of the abdomen. The history of its appearance is interesting and may be considered to lend some support to one of the theories of the causation of infantile hemiplegia. At the age of one year and seven months the child was seized with convulsions and remained unconscious for about a week, but no loss of power in either arm or leg was apparently present.[1] Towards the end of the week the right leg and thigh were swollen and the dilated abdominal vein was noticed to have appeared. The girl is said to have been bright and intelligent at the time of the attack and to have been able to say a few words. After recovery of consciousness no attempt was made to speak for more than two years and the girl, now 10 years of age, is still unable to read. She is of cheerful disposition and on good terms with her brothers and sisters, but has not sufficient intelligence to be entrusted by her mother with the most simple errand. No indication of weakness of either side of the face is present and there is no defect of sight or hearing. There is no weakness of either arm or leg and the knee- and elbow-jerks and reflexes are equal on the two sides. The vein seen in the illustration runs upwards from the centre of the right groin to the costal margin, where it divides into several branches which spread over the front of the right half of the chest, some reaching nearly as high as the clavicle. Below the point of division the vein nearly equals an ordinary penholder in diameter. The blood in it flows upwards. When emptied from above it remains empty, but it immediately fills on removing the pressure of the finger. The girl has five brothers and sisters, two of whom have attended the hospital as out-patients. One boy has had empyema following pneumonia, but mentally and physically they present no defect. In this girl also the head is well-shaped and she is tall rather than short for her age. There is nothing to suggest congenital syphilis. A further detail in the history may be worthy of mention. The mother attributes the attack of convulsions to the falling of the child into a dirty stream about three weeks before their onset. The child was nearly drowned, and after being pulled out she vomited a considerable quantity of water which had been swallowed.

In this case there has obviously been blockage of the external or of the common iliac vein. Such blockage of acute onset may most reasonably be attributed to thrombosis. At the time that the obstruction of this vein occurred there were convulsions followed by unconsciousness of a week's duration which terminated in permanent mental defect. The association of acute cerebral symptoms with mental defect as a sequel points to some definite lesion in the brain.

---

[1] Recently in going through my notes I discovered that this girl had been seen by me in August, 1896. The history then given by the mother in the main is the same as that recorded here, but a few additional facts of importance are mentioned. At the onset of the unconsciousness there are said to have been twitchings of the right side of the face and the mouth was drawn to the right side. Jerking movements were also present in the right arm and the right leg. The child could not walk for five or six weeks after the attack and then limped on the right side. At the time she attended the out-patient department she was said to be using the left hand in preference to the right, but no weakness of the grasp of the right hand could be detected. She was then commencing to say a few words, but was said to have been able to speak better before the attack, since which more than three years had elapsed.



An enlarged superficial abdominal vein in which the blood flows upwards. The child is mentally weak, and the cerebral defect dates from an acute illness which was followed by the appearance of the enlarged vein.

The evidence of thrombosis of a vein within the abdomen strongly suggests that the primary cerebral lesion was also a thrombosis.

No hemiplegia was present in this case and the lesion was probably outside the motor area. Apparently, however, thrombosis of a vein in the region of the motor area need not occasion hemiplegia. I have made a necropsy upon a case of death from broncho-pneumonia in a boy, aged four years, where the left cerebral vein was distended with a pale stratified thrombus, yet no weakness of either side had been noticed during life. Although the vein was completely blocked and the deposition of clot had apparently been taking place for several days before death the disturbance of the neighbouring circulation had not been great. There was little congestion of the pia-arachnoid and no softening of the cerebral substance was present. The morbid appearances were very different in a case where veins situated over the parietal lobe, passing up to the superior longitudinal sinus, had become thrombosed There the swelling and softening of the convolutions were very great. In this second case hemiplegia was present. The thrombosis occurred as a complication of ascites due to cirrhosis of the liver in a girl, aged 12 years.[2] In these two cases thrombosis of cerebral veins occurred as a complication, not as the primary disease, and consequently they do not necessarily lend support to the theory that hemiplegia of acute onset occurring in a healthy child is due to this cause. In one of the cases cultures from the thrombosed vein showed streptococci and in the other the thrombosis was probably secondary to the absorption of organic bodies contained in the peritoneal effusion which was disappearing at the time of onset of the hemiplegia. Cultures taken from thrombosed vessels in the great majority of instances show micro-organisms to be present. It is easy, therefore, to understand that when a child is suffering from some disease in which micro-organisms can readily obtain access to the circulation thrombosis of veins and arteries may occur, and it is not surprising that in a few cases in which hemiplegia in children has been present as a complication of acute disease thrombosis of a cerebral artery or of a vein has been found to have been the cause.

Hemiplegia of acute onset in an apparently healthy child is more difficult to explain. If the paralysis be due to a blood infection resulting in thrombosis of a cerebral vessel one would suspect some indication of ill health before the onset of the acute cerebral attack. Generally, however, the child is described as being strong and well at the time of the onset of the convulsions which usher in the hemiplegia. Yet apparently other manifestations of a blood infection, such as purpura, may show themselves suddenly, and one would think that the normal condition of the blood must be much impaired before a rigor can take place, but when a rigor is a symptom of commencing acute disease it has rarely been preceded by any feeling of ill health which has attracted the patient's attention.

It is of some interest to note that in the present case the child swallowed a considerable quantity of dirty water a short time before the onset of the cerebral affection, and it is not unreasonable to suppose that some organisms contained in the water were the cause of the thrombosis.

It may be added that, if thrombosis due to a morbid blood condition be allowed to be a probable cause of hemiplegia in an apparently healthy child, it is more easy to believe that such thrombosis occurs in a vein than in an artery. It must be remembered, however, that thrombosis of cerebral arteries as well as of veins has been found to occur as a complication of disease in children. I have met with both conditions in the post-mortem room. In the above case, although there was obviously thrombosis of a vein within the abdomen, if thrombosis existed also within the cranium it does not necessarily follow that the vessel affected was a vein. When the blood presents a liability to clot during life, thrombosis may sometimes arise in a vein in one place in the body and in an artery in another. In this case it cannot be proved that thrombosis occurred in either a cerebral vein or an artery, but it may be again mentioned that consideration of various points in the case seems to indicate the probability of such a lesion having been present.

Yet while no evidence of hemiplegia remains, the existence of cerebral defect shows that the brain has suffered injury The additional facts mentioned in the footnote seem to show that weakness of the right side was at one time present. The occurrence of such injury as the sequel of an acute cerebral attack in which ante-mortem clotting in a cerebral vessel was very probably present may be considered to lend support to the thrombosis theory of the causation of infantile hemiplegia.

Bristol.

THE PROSPECT OF CURE IN CANCER.

BY HORACE MANDERS, M.D. BRUX., F.R.C.S. ENG.

CANCER is a disease chiefly of the grand climacteric, when youth has attained its old age and the organs especially pertaining to that epoch are beginning their decadence, so, with the lessening supply of the vital fluid to those parts whose function is no longer needed in the economy come diminished vitality and a more feeble resistance to adverse influences introduced from without. So beautifully harmonised is this decadence in general that there just remains sufficient vitality to maintain the negative energy of resistance, but not enough to produce the active energy of function until physiological atrophy is arrived at. So long as these two balance each other in the normal proportion of decadence the system is protected, but should anything cause a disturbance of the harmony those parts in which the equilibrium is upset become open to assault and invasion from without. It is not my object here to enter upon the causes that may disturb the balance

Some remedies are designed to act against the *origo mali*, whatever that may be—plasmodium, zyme, or enzyme—and which will be determined eventually, but the great point in the treatment of cancer is to direct our attention to the natural forces inherent within the body.

---

[2] Notes of both of these cases were read before the Society for the Study of Disease in Children in November, 1900 (THE LANCET, Dec. 8th, 1900, p. 1653) See also Brit. Med. Jour., July 6th, 1901.

It is a matter of common knowledge that the secreting power of cells can be influenced by the action of certain drugs acting on their protoplasm. Pilocarpine, for example, and arsenic have a beneficent action, but electricity alone is capable of directly and profoundly affecting the molecular changes that go on within the cells, of acting as a powerful tonic and restorative to the protoplasm itself whereby metabolism is promoted and resistance to adverse influences is greatly augmented. The immediate effect of this is to restore the lost equilibrium.

The term "electricity" comprises much, but the particular form of electricity only that affects cells so profoundly modified as are those of cancer is the current of high frequency and high potential discovered by Tesla and first introduced into therapeutics by d'Arsonval. It is now nearly two years ago (November, 1899) that I advocated the use of these currents in the treatment of pulmonary tuberculosis in combination with the open-air treatment. On account of the outbreak of the war in South Africa I was called away from pursuing further studies in that direction, but the successful results obtained by Mr. Chisholm Williams in 43 cases of phthisis treated by him recently by these currents are so clear that there can be no possible doubt in the mind of anyone who has observed the cases under this treatment that the protoplasms of the various cells of the body are marvellously vitalised and resuscitated, to the extent that they are once more able to repair the consequences of invasion and to resist attack. No doubt the leucocytes also are stimulated to secrete suitable alexines. I would wish to point out that the good effects of the Tesla currents are not limited to tuberculosis of the lungs only, but that if applied locally through a highly exhausted unipolar glass tube to tuberculous affections of joints and other parts a result equally satisfactory may be expected.

In cancer we may not have to deal with an invading microbe, yet it is evident that some malign source is at work whose influence the natural defensive powers of the body have become unable to resist, and it is only reasonable to infer from analogy that if these inherent powers could be re-vitalised to the extent that generally obtains in the equilibrium of health, as has been done in tuberculosis, then there is a definite prospect of a cure for that even more intractable disease cancer. If these inherent powers did not exist we should all fall victims, as it is unreasonable to suppose that we are not constantly exposed to the source of cancer just as we are to that of tuberculosis, of which we are now well aware.

Two cases have already been recorded, one in America and the other in the *British Medical Journal*, in which cancer has been arrested by means of the x rays, and I am acquainted with a third in which the improvement has been marvellous; but the treatment has not been without its disadvantages, and I am very strongly of the opinion that it is not the ultra-violet or x rays that produced the result, but that the real agent was the oscillatory violet rays which are generated at the same time as the former but are few in quantity and are masked by the greater quantity of the x rays. With Tesla's currents, run from a solenoid resonator into a unipolar highly exhausted glass tube as used by Tesla, one finds an enormous number of these violet rays given off with a few x rays—so few as to be a negligible quantity. Now, these violet rays, of tremendous speed of alternation from oscillation, amounting to millions per second, possess the advantage of being very easily applied, locally, to very small surfaces of the body—an advantage which is not possessed by the x rays, as these need, for local application, a considerable arrangement of covering for the protection of adjacent parts, otherwise severe burns are probable. Also it is impossible to charge the body as a whole with the x rays, a matter which is quite easy when the violet rays of the solenoid are used, whereby the protoplasm of the cells throughout the body is stimulated in its molecular action. It is well known to x-ray workers that after a little use a greater resistance is set up in the Crookes's tube and that rays of a different character are produced; in fact, the rays emitted from a Crookes's tube at different speeds of alternation, resistances, &c., are not yet thoroughly understood, or sifted for the different work expected from them.

It is quite probable that there is more than one cause of the various forms of cancer, and that this is the case I am inclined to think from the results of the yeast treatment in my hands, sometimes so efficacious in arresting this disease, at other times with little or no effect. Therefore I think it unwise to limit oneself to any one form of treatment, but I am of opinion that in these currents of high potential and exceeding frequency we have a means, hitherto unknown, of stimulating the vital energy of cells and of enabling them to utilise, by taking into their protoplasm, auxiliary remedies of which hints have been given, and that sometimes one and sometimes another, when used in conjunction with these currents, will be found to be the particular one needed. The progress of my cases undergoing this treatment is already most encouraging.

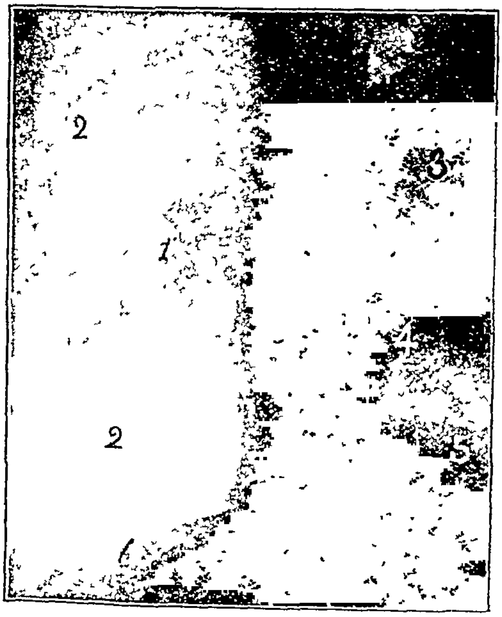
Bentinck-street, W.

A CASE OF PNEUMOTHORAX SHOWN BY THE ROENTGEN RAYS.

By ERNEST W. MARTIN, M.B., CH.B. EDIN.,
RESIDENT MEDICAL OFFICER, CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK, E.

THOUGH within the last year a large amount of work has been done with the x rays in connexion with medical diseases of the chest, as far as I can ascertain up to the present time no photograph of the chest in the condition of pneumothorax has been taken. The case I obtained the negative from was one of pneumothorax in connexion with caseous tuberculosis, and the photograph is of interest as showing more accurately than physical signs could demonstrate the actual condition of affairs within the thorax and the displacement of the viscera.

The patient, a man, aged 22 years, was admitted into the City of London Hospital for Diseases of the Chest, Victoria Park, on August 5th, 1901. He gave a history of continuous cough for the last two years, together with loss of flesh, sweating, and shortness of breath. On examination he was found to be suffering from chronic phthisis, both lungs being affected throughout. The apex-beat was in the fifth intercostal space one inch internal to the vertical nipple line. The history of the attack of pneumothorax was as follows. On April 12th at 5 P.M., after a fit of coughing, he was suddenly seized with severe pain in the left side, accompanied by dyspnœa, the latter not being very marked. On examination it was found that the percussion note over the apex posteriorly was resonant, but that there was no displacement of the heart; at 7 P.M., after another fit of coughing, the patient had more pain and the dyspnœa



1. Collapsed left lung. 2. Air in pleural cavity. 3. Tuberculous lung. 4. Right margin of heart. 5. Right dome of diaphragm, normal. 6. Depressed left dome of diaphragm. The heart is not seen at all to the left of the vertebral column, the shadows of the vertebræ being quite clear. The intercostal spaces on the left side of the chest are broader than are those on the right.

increased to orthopnœa. On examination it was then found that the percussion note was resonant all over the left side of the chest back and front, the cardiac dulness was obliterated, and the heart's impulse could not be felt at all to the left of the sternum. The bell sound was easily obtained The patient died on April 13th from syncope. The skiagram was taken shortly after death; an exposure of three minutes was given, the tube being at a distance of two feet above the chest

At the necropsy on puncturing the chest-wall over the left pleural cavity gas escaped under pressure. On opening the chest the cavity of the left pleura was found to contain a large quantity of gas, the lung being collapsed and compressed and the heart being displaced so as to be almost in the middle line. The pneumothorax extended throughout the pleural cavity; there were a few recent adhesions at the apex. No fluid or pus was present. The perforation had taken place posteriorly and above the root, there being a small slit-like opening leading into the lower part of an apical cavity. The lungs showed caseous tubercle throughout. There was no recent pleurisy.

Remarks.—In a case such as the above there is of course no difficulty in making a diagnosis of the condition present and the chief interest of the skiagram, apart from what may be learned from it by the practical x-ray worker, lies in the very clear demonstration of the position of the displaced viscera in a case where the lung is not firmly bound by adhesions and where there is a positive pressure within the pleural cavity. The flattening and downward displacement of the diaphragm could hardly be made out by physical signs; the position taken up by the lung and the complete displacement of the heart from the left side of the chest are all clearly shown in the skiagram. Another point well brought out is the broadening of the intercostal spaces on the side of the pneumothorax. In addition the skiagram shows the shadows thrown by caseous tubercles, the portion of lung immediately above the right arch of the diaphragm being the only clear piece of lung shown.

For permission to publish these notes I am indebted to Dr. Clifford Beale, under whose care the case was.

P.S.—Since sending this case to THE LANCET I have shown in the museum of the British Congress on Tuberculosis five cases of a similar condition; and I believe other cases are on record, one being shown by Professor Béclère of Paris

Victoria Park, E.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF EXTRA-UTERINE GESTATION; RUPTURE INTO THE GENERAL PERITONEAL CAVITY; OPERATION; RECOVERY.

BY D. LLOYD CLAY, M.R.C.S. ENG., L.R.C.P. LOND.

ON April 19th, at 5 A.M., I was called to see a woman, aged 31 years, who presented all the signs of internal hæmorrhage. Her face was deadly pale and her pulse was very quick and almost imperceptible. She was bathed in cold perspiration and she complained of agonising pain in the lower part of the abdomen, chiefly on the right side, and also about the right shoulder. On examination slight distension of the lower part of the abdomen could be made out and there was great tenderness in the right iliac region, the slightest touch causing the patient to call out. The breathing was very shallow and purely thoracic. Per vaginam I was able to make out a little fulness on the right side and behind the uterus. The history of the case was as follows. For six weeks she had suffered from irregular hæmorrhages accompanied by shooting pains; the discharge would sometimes last two or three days At times she passed some solid material. Previously to the appearance of these hæmorrhagic discharges she had not "seen anything" for six weeks. From the above symptoms and the history I diagnosed extra-uterine gestation (three months) with rupture into the peritoneal cavity, and I called in Dr. W. Fell who confirmed the diagnosis and advised immediate operation.

At 7 A.M., after the patient had rallied slightly, I accordingly opened the abdomen midway between the pubes and the umbilicus, the incision being three inches long. On reaching the peritoneum that membrane bulged into the wound and on being opened a quantity of blood escaped. I then easily reached the gestation sac, transfixed the base with an aneurysm needle threaded with stout silk, and tied it in two places. One ligature was cut short, while the other was thrown round the whole pedicle and tied again and the sac was removed. All clots were removed, Douglas's pouch was well sponged out, and the abdominal cavity was washed out with large quantities of boric lotion, saline solution being used at the finish. The abdominal wound was now stitched in the usual way and the patient was put back to bed, having stood the operation, which lasted 35 minutes, very well. Vomiting was very troublesome for the first 24 hours, and the patient was given ice to suck and small doses of morphia hypodermically. The patient did very well up to the nineteenth day, when I was again sent for. On examination some fulness and tenderness could be made out in the lower part of the abdomen. The temperature was 102 6° F. I now felt sure that there was some collection of pus somewhere in the pelvis. On the twenty-first day there was great abdominal distension, together with retention of urine. The temperature was 101°, the pulse was quick, and great pain was complained of. Per vaginam a fluctuating swelling could be made out in Douglas's pouch, pushing the uterus upwards and forwards, the cervix being felt right above the pubes. The posterior vaginal wall was very tense and bulged externally. Pelvic abscess was diagnosed, and I decided to make an opening as soon as possible per vaginam. On examination per rectum, however, the abscess was found pointing and on the verge of bursting about three inches above the anus. Slight pressure by the finger was sufficient to open the abscess and a large quantity of pus mixed with blood escaped. There was immediate relief; the temperature dropped and the patient recovered without a bad symptom.

I report the case on account of its successful result and because it was so very heavily handicapped. The operation had to be done in a great hurry and in a private house—where, of course, strict antiseptic principles could not be carried out. The patient was so blanched that not a single vessel had to be seized on cutting through the abdominal wall.

Wellington, New Zealand.

A CASE OF PAGET'S DISEASE OF THE NIPPLE OCCURRING IN A YOUNG SUBJECT.

BY RICHARD ALCOCK, M.D. VICT.

SOME time in 1892 I was consulted by a woman on account of an eczematous condition of the right nipple and areola She was 28 years old, was married, and had borne children. She came to me from time to time afterwards, but no treatment had any effect In 1893 I advised her to have the entire breast removed. The condition at that time was as follows. Occupying the situation of the areola was a slightly raised eczematous surface, moist, red, and exuding a discharge clear, yellow, and viscid. There was no ulcer, strictly speaking, the surface of the sore retaining a cutaneous appearance. The nipple itself was non-existent; as the patient expressed it, "it had scaled away," probably a literal statement of actual fact The condition was sharply limited to the region of what was formerly the areola. I advised complete removal on account of the known tendency to carcinoma in these cases and also because a nippleless mamma would be a useless appendage.

In November, 1893, the patient was removed to the Goole Cottage Hospital and the operation was performed by my friend Dr Macdonald Brown, surgeon to that institution. The after-history was uneventful Up to the present time (1901) there has been no recurrence and she has enjoyed good health since and given birth to further children

I prepared sections for the microscope, from one of which a drawing was made under a low power (vide illustration) It will be seen that there is a considerable proliferation of the epithelium downwards into the subcutaneous tissues in the form of branching and anastomosing columns of cells. The vascular papillæ reach up as far as the free surface and no doubt account for the exudation On the surface there are abundant evidences of loss of substance by shedding of the superficial epithelial cells. The morbid conditions were limited to the cutaneous tissues. The condition is clearly a neoplasm, simulating epithelioma to a certain extent, but differing from it in many respects, notably in the entire absence of "nests." I have thought it worth while to place the case on record on account of the youth of the patient and also on account of the microscopical characters which I have not seen described as here presented in any text-book to which I have immediate access.

HÆMORRHAGE DUE TO INCOMPLETE ABORTION.

By F. W. ERNEST HUTCHISON, M.B., C.M. GLASG.

A WOMAN, aged 36 years, who had been married 10 years and was the mother of four children, consulted me in January last, complaining of losing blood at different times, first dating the symptom from a miscarriage which she had had six months before. She was two and a half months pregnant, she said, when the miscarriage took place. Just before consulting me she was losing a much greater amount of blood than previously. She was extremely anæmic and weak. On examination blood could be seen escaping from the os uteri. The sound passed three inches and the uterus was slightly enlarged. The patient losing so much blood and being so weak I decided at once to explore the interior of the uterus. This I did in the usual way by Hegar's dilators, and passing the finger inside I at once detected a number of small lumps studded over the surface. These were removed by the finger-nail chiefly and also by Récamier's curette. Afterwards I applied pure carbolic acid to the endometrium Subsequently the patient menstruated normally in every respect.

Kelvedon, Essex.

LONDON TEMPERANCE HOSPITAL.—A stained-glass window has been recently unveiled at the London Temperance Hospital by Mr. Alderman Strong, chairman of the board of management The window is the gift of the brother of a patient, is the personal work of the donor, and was given as a token of appreciation of kindness and benefits bestowed by the hospital staff. The window is pictorial in design, the central figure being that of Christ, surrounded by those in fetters, the suffering, and the young; underneath is inscribed the text, "Come unto Me, all ye that labour and are heavy laden." On either side are angels praying and shields bearing the words, "Amor," "Pietas," "Patientia," and "Fortitudo," surmounted by angels in glory; the canopy is white and gold. Among those present were the Rev. Dawson Burns, D.D., Colonel Sheffield, L.C.C., and the members of the board of management.

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF TUMOR CEREBRI IN WHICH ROTATION OF THE TONGUE WAS PRESENT.

(Under the care of Dr. J. ROSE BRADFORD.)

THE abnormal movement of the tongue described in the case recorded below is remarkable and difficult to account for by the light of our present knowledge. In cases of lingual paralysis it is very desirable to determine, when possible, which individual tongue muscles are paralysed, both intrinsic and extrinsic. For the notes of the case we are indebted to Mr. A. Ernest Jones, late house physician.

A woman, aged 37 years, was admitted into University College Hospital on Jan. 5th, 1901, with the following history. She had suffered from headache, which was not localised, for two years. Attacks of vomiting had occurred every month for the past five months, lasting for three days. These attacks had no relation to food. There was no nausea. She had had fits for three years. The convulsions started in the right arm or leg and never became general. They were accompanied by no loss of consciousness and could be stopped by sitting on the twitching hand. She had had two "strokes." The first "stroke" occurred on August 21st, 1899, when she became unconscious after several fits and was comatose for six weeks. There was no vomiting. The right arm, leg, and face were found to be paralysed on the tenth day. The second "stroke" occurred on Dec. 26th, 1900, and left her weak in the left side of the face. Her memory had been failing for 18 months.

On admission there were slightly marked cerebral hemiplegia on the right side, involving the face, and fine occasional tremor in the right hand, which was increased by exertion. Sensation was unaffected. The movements of the eye and the pupils were natural. The palate moved well. On opening the mouth the lower jaw distinctly went over to the left, and the left masseter was weak. The tongue, when protruded, went to the left, but not more than would be accounted for by the jaw movement. It, however, rotated in such a manner that the dorsum looked upwards and to the left. It was horizontal when at rest and showed no atrophy or trophic changes. Well-marked optic papillitis with commencing atrophy was present, the inflammation being more marked on the left side than on the right. The sight was unaffected. There was no other evidence of involvement of the cranial nerves. The sphincters were unaffected. The intelligence was dulled.

The patient died seven weeks after admission. During that time she had 50 or 60 fits, no aura occurring. The only changes in the physical signs were that the rotation of the tongue became less marked in the last two weeks of life and rigidity of the left limbs supervened a few hours before death. Twitching of the right face also frequently occurred

Necropsy.—At the post-mortem examination a subcortical tumour was found on the left side of the cerebrum. It was five or six centimetres high; it had its centre opposite the arm area, involved the corpus callosum, and was evidently pressing on the opposite hemisphere. Microscopically it was a round-celled sarcoma

Remarks by Mr. JONES.—I have been unable to find a case of rotation of the tongue occurring clinically anywhere recorded. Beevor and Horsley[1] state that on stimulation of a localised area of the cortex in the lower part of the ascending frontal convolution opposite the upper end of the inferior transverse frontal sulcus of Eberstaller the tongue rotates in such a manner that its dorsal surface becomes applied to the cheek of the same side. This movement was not obtained by the same authors[2] on stimulation of any part of the internal capsule. The movement therefore appears to have been described experimentally before it was noted clinically.

---

[1] Philosophical Transactions of the Royal Society, vol. 185B., Part i., 1894, pp. 54-58.

Applying the above knowledge to this case, as the centre for this movement was assumedly paralysed, when the tongue was protruded one might expect the opposite centre to have unopposed action and to rotate the tongue so that its dorsum was applied to the right cheek, whereas what really happened was that its dorsum was applied to the left cheek. This anomaly is parallel to the difficulty that meets the clinician with respect to the experimental and clinical deviation of the tongue—namely, that appropriate stimulation of the left cortex causes the tongue to deviate to the right, whereas in hemiplegia from tumour, &c., which destroys that centre, the tongue also deviates to the right when the patient is asked to protrude it. Beevor[3] has suggested the following explanation of the apparent anomaly. Stimulation of a localised area with an electrode is not parallel with asking a patient to put out his tongue, but rather with asking a patient to touch one cheek with the tip of his tongue, so that it is not justifiable to antagonise the two facts although they apparently contradict each other. In health protrusion of the tongue is a bilateral movement, but in disease it is not known by what movements protrusion is effected, and up to the present no complete explanation has been offered as to why the tongue deviates to the paralysed side in hemiplegia. The presence of the rotation phenomenon clinically suggests a lesion in or near the cortex, but as to the side of the lesion I do not think that one can at present dogmatise. I am indebted to Dr. Rose Bradford for permission to publish the case.

NORFOLK AND NORWICH HOSPITAL.

A CASE OF MYOSITIS OSSIFICANS.

(Under the care of Dr. F. W. BURTON-FANNING.)

WITH our present absence of knowledge of the etiology of myositis ossificans the record of every case is desirable. In one respect the following case differs from most of those which have hitherto been reported; there is very distinct evidence of the occurrence of the disease in the patient's father. Dr. W. P. Herringham[4] says: "All agree that it is congenital but not hereditary"; and the absence of any history of inheritance of the disease is certainly marked in most cases. For the notes of the case we are indebted to Mr. A. Ll. Vaughan, late house physician.

A man, aged 33 years, was admitted into the Norfolk and Norwich Hospital on account of increasing difficulty in opening his mouth. He gave the following history. At the age of eight years his left shoulder gradually became stiff without any previous injury or pain. The stiffness had only progressed slightly. At the age of 12 years the movement of the right knee became impaired and had gradually become worse till all power of movement had gone. Following this in order came stiffness to the left hip, sides of the chest, and lower part of the back. The immobility of these parts had been slowly increasing since the onset. At the age of 26 years the right arm from the shoulder downwards was much swollen, the skin becoming red and tender. The inflammation was so acute that the arm was thought to be poisoned. The swelling, however, passed off and then the arm was found to be absolutely fixed in the extended position while the movements at the shoulder—previously impaired—were further diminished. Flexion and extension remained at the wrist, but the forearm could only be supinated through half the natural extent. Two years later stiffness of the right hip was noticed. During the winter of 1898 difficulty in opening the mouth began but passed off during the summer, only to return, however, in the following winter in a worse degree. There was some slight improvement in the summer of 1900, [illegible] the legs [illegible] but had [illegible] an increase of his malady directly to any injury. He had been remarkably free from any other disease except for constant trouble with his eyes, which were affected with ciliary blepharitis.

The patient's family history is worthy of special note. His grandfather, who was a healthy man and lived to the age of 60 years, had two sons, of whom one was in perfect health and had no congenital deformities; the other one was the father of the patient and suffered from myositis ossificans, dying at the age of 33 years from an accident. In this case the disease began at the age of 15 years in the right arm and was attributed to an injury from a fall. The disease had steadily progressed, but had not reached the same degree as that found in the patient. This man had a congenital deformity of the thumbs, there being no joint beyond the metacarpal one.

The present patient was a spare man with an unhealthy look due to the inflammation of his eyelids. The face was directed downwards and forwards due to slight flexion at the hips and fixation of the vertebræ The left foot was kept about six inches in advance of the right and there was slight flexion of the left knee. Progression was effected by sliding the left foot forwards by using all the power of flexion that remained in the left knee and ankle and then dragging the right leg up to it.

Examination of the muscular and osseous systems showed that both erectores spinæ were almost completely replaced by bone which had retained the natural outline of the muscle and which prevented any movement whatever in that portion of the spine over which the muscles lie. The deep muscles at the back of the neck were similarly affected and the only movements along the central axis of the body left to the patient were a slight rotation and flexion of the head. Both of these movements were limited. There were bony plates between several of the ribs on each side and along the anterior border of the left quadratus lumborum was a hard band fixing the twelfth rib to the crest of the ilium. These growths together prevented any movement of the chest except in the region of the first two ribs which moved slightly on respiration. The teres major and pectoralis major on each side had their distal halves bony and by them shoulder movements were nearly prohibited. On the right humerus immediately above the olecranon fossa was a bony mass of about the size of a walnut which involved the whole thickness of the triceps, binding the muscle to the bone and preventing any flexion of the elbow. There was another similar growth over the upper ends of the radius and ulna limiting pronation and supination. In the lower extremities the quadriceps extensor on each thigh was almost replaced by bone. There were diffuse osseous growths round the head of the right fibula and enlargement of both internal malleoli and also of the tuberosity of the right scaphoid. There were no growths on any other bones of the feet. The big toes on each foot presented the deformity met with typical in this disease—namely, slight hallux valgus with shortening and broadening of the phalanges which were fused together.

Remarks by MR. VAUGHAN.—In considering the new formation of bone found in this patient two groups present themselves: (1) deposition along the course of a muscle, and (2) deposition over some existing prominence of bone. The majority of the new bone belongs to the first group and seems to be an ossification commencing at the attachment of muscle to bone and extending along the muscle in a manner analogous to the "rider's bone." In a great number of the recorded cases there is evidence of injury preceding a deposit of bone, making the analogy more striking, but in this case no injury has been assigned as a cause of any increase of the disease while, on the other hand, there was marked progression of the affection during the winter months with a remission during the summer.

The disease for the most part is chronic, but occasionally, as in the case of the right arm of this patient, there is an acute inflammatory process, accompanied by much pain. In the *United States Journal of Medicine*, De Witt has described minutely the sequence of pathological events, prominent amongst which is a phlebitis accompanied by an exudation into the connective tissue of the muscle rich in osteoblasts. Such a lesion would explain satisfactorily all the symptoms present during an acute process preceding the deposit of bone in the right arm of the patient now discussed, but this is the only instance in which any acute inflammation had occurred during his malady nor has there been pain of any character in any other part of him that could be attributed to his disease Pain as a symptom of this disease is remarkable for its absence, whereas in rheumatism and osteo-arthritis it is most constant.

In the present instance there are no masses of bone lying free in the muscle substance, but all are connected to bone. The joints are free from disease and what movement is left to the patient is unaccompanied by pain, creaking, or grating. In conclusion, I would draw attention to the fact of the disease occurring in the parent and being in him associated with a congenital deformity of the thumbs. I am indebted to Dr. Burton-Fanning for permission to record the case.

Reviews and Notices of Books.

Anæsthetics and their Administration. A Text-book for Medical and Dental Practitioners and Students. Illustrated. By Frederic W. Hewitt, M.A., M.D. Cantab., Anæsthetist to H.M. the King. London: Macmillan and Co. 1901. Pp. 552. Price 15*s.* net.

The first edition of Dr. Hewitt's manual was issued in 1893: the present is, however, more than a second edition, as the author has recast his material and added much which is important, as well as including two sections dealing respectively with the history of the introduction and development of anæsthetics and the physiology of the subject. We welcome the last-mentioned addition, for no rational knowledge of anæsthetics can be acquired without a thorough grasp having been obtained of the very large amount of experimental work which has been prosecuted during the last half century. The views of Dastre are prominently advanced in these pages, but a meritorious effort has been made to present other schools of thought. Even in the 50 pages devoted to the subject it is not possible to give anything like a complete *résumé* of the researches bearing upon the physiological aspects, and it is difficult to avoid at times attaching what some physiologists may regard as undue weight to the opinions of certain workers and too little to those of an opposite school. The alteration which under many conditions takes place in the activity in conveying power of the blood corpuscles, influencing as it does the oxidation and vitality of the tissues of the body, is one which must be reckoned with when the physiology of anæsthesia is being discussed, and the omission of the investigations upon this point breaks the chain of reasoning, especially in connexion with the gases in blood from anæsthetised animals. Most of the analyses of the gases in blood which have up to the present been given must not be accepted as final since many precautions and errors of experiment require examination. The whole subject is worthy of fuller elaboration. We gather that Dr. Hewitt accepts the views of Professor Leonard Hill with regard to the much discussed question, "Does primary cardiac syncope occur under chloroform?" The arguments advanced by the Hyderabad Commission, and more recently in Surgeon-Lieutenant-Colonel Lawrie's book on Chloroform, do not appeal to Dr. Hewitt as sufficiently convincing, for he says (p. 91): "To sum up, then, on this much disputed point, it may be regarded as established that during chloroform anæsthesia this anæsthetic directly produces a depressing effect upon the heart itself; and that while it is true, not only in the physiological laboratory but in actual practice, that respiration generally ceases before cardiac action finally fails, it is the want of cardiac action which is the essential factor in the causation of death under chloroform."

In Part II. various matters connected with the selection of the anæsthetic are considered and this section, taken in conjunction with Chapters XIII. and XIV. dealing with anæsthetic mixtures and sequences, presents the writer's views upon the merits of the agents in common use. Nitrous oxide given with oxygen is recommended for brief cases, and nitrous oxide followed by ether for prolonged operations. The nitrous oxide and oxygen mixture is not advocated for long cases, although the author admits that this mixture may in some few instances be employed for periods exceeding two or three minutes. Such sequences as nitrous oxide and ether followed by chloroform, and chloroform or the A.C.E. mixture in sequence with ether, also find favour with Dr. Hewitt and thus far it appears that the author falls into line with the usual custom among English anæsthetists. Those who have used oxygen with ether in appropriate cases will not agree with the adverse criticism which Dr. Hewitt pronounces upon the method. As, however, the "best" plan is said on page 285 to be to introduce the oxygen through a small tube into a Rendle's inhaler the failure to obtain more satisfactory results may be due to the methods suggested. Dr. Hewitt is, perhaps, less in accord with the prevalent feeling in not reprobating the administration of morphine concurrently with chloroform, but he is probably quite correct in saying that provided morphine is only employed in carefully selected cases it should be retained in the armamentarium of the anæsthetist. The addition of atropine appears to us to be advisable even if, as Dr. Hewitt suggests, there is at present an increasing disbelief in the danger of cardiac failure through vagal inhibition. It must be admitted that many of the undoubted dangers of morphine given in association with chloroform are removed when atropine is added to the other alkaloid. In the chapter dealing with Mixtures, Schleich's method of employing a solution of chloroform, ether, and petroleum ether in different proportions is accorded a place. These solutions have been very extensively employed in Germany as well as in the United States and have been highly spoken of. Dr. Hewitt says that he is not aware of their having been employed in this country, but we believe that they hav been tried with success at the London Hospital by Dr Probyn-Williams who regarded his trial as encouraging.

In describing apparatus and the methods of employing them Dr. Hewitt is peculiarly felicitous. He devotes most of his space in the sections dealing with the practical side of his subject to the methods and apparatus which he himself employs. Other methods are detailed although less fully. He is not in favour of Clover's larger gas and ether inhaler, although we believe that this apparatus is much used and is by many preferred to the smaller regulating inhaler even with the numberless modifications to which it has been subjected. Certainly the charge that the larger apparatus cannot be cleansed is inaccurate, as we have seen it constructed in such a way as will allow of every part being fully cleansed and disinfected. For chloroform administration Dr. Hewitt advocates the employment of a Skinner's mask and a drop bottle, using Junker's inhaler only in nasal and oral surgery. We find ourselves in accord with him when he insists upon the peril of accepting the use of Junker's or any inhaler as a "perfectly safe" method, but we venture to think that the plan which he suggests is open to a similar objection. Dr. Hewitt's favourite anæsthetic appears to be the A.C.E. mixture or a sequence containing it and his description of his method of employing it is admirable. Sections are given dealing with bromethyl, amylene (pental), and ethidene dichloride, but these agents do not appear to have appealed to Dr. Hewitt who, rightly we think, rather deprecates their use. Professor Wood's careful study of the effects of dichloride of ethidene upon the heart clearly shows that that anæsthetic is at least as dangerous a circulatory depressant as chloroform. Nitrogen, which comes in for a rather full notice, cannot, we think, ever be worth the attention of the practical anæsthetist on account of its comparative inertness. The same remark applies to carbonic dioxide, although Waller's careful work upon this gas deserves notice. In comparing the various anæsthetics Dr. Hewitt comes to the conclusion that ether is at least five times safer than chloroform judged from statistics—a less favourable result than Waller obtained in his research upon isolated nerve. His ratio of safety was seven times in favour of ether. The common criticism that ether kills by its after-effects makes Dr. Hewitt's careful study of the whole question of dangers and after-effects particularly valuable. He has since the issue of his first edition altered his views with regard to so-called ether pneumonia. His experience has convinced him that certain patients do succumb to lung trouble apparently initiated by ether inhalation. He has not, we think, quite appreciated the undoubted fact that bronchitis and even broncho-pneumonia are by no means uncommon in hospital practice after chloroform, especially after prolonged operations. We regret that the limits of his space prevented Dr. Hewitt from giving an even longer discussion of this most important question. Again, renal dangers have been carefully studied and it is reassuring to find that Dr. Hewitt's experience is in favour of ether. The section dealing with the dangers and *contretemps* of anæsthesia is very valuable, but it might, we think, be made more so by some re-arrangement and division into paragraphs. Dr. Hewitt declares himself little in favour of drugs, and this probably accounts for his comparatively slight notice of the use of strychnine, a drug in which Professor Wood places the utmost confidence, and for the omission altogether of the recently advocated use of freshly prepared suprarenal capsule, which, according to Schäfer, is the most powerful remedy in cases of circulatory failure at present known. Among remedies "forced respiration," or pulmonary perflation, has in the hands of Professor Wood proved of the greatest value. We believe, indeed, the authority given goes so far as to say that death from respiratory failure will never occur when this plan is adopted. Although Fell's method is mentioned on p. 464 Dr. Hewitt has not emphasised the use of forced respiration as opposed to the routine plans of Sylvester and Howard. What Dr. Hewitt insists is that whatever restorative measures are adopted the anæsthetist should devote himself wholly and solely to restoring respiration and should not allow his attention to be diverted from that object. Undoubtedly "prevention is better than cure" in anæsthetic emergencies, and so the sections, which Dr. Hewitt has carefully written, dealing with preliminaries and contained in Chapters V. to VIII. inclusive, should be read with close attention. The author is right in insisting upon the extreme importance of posture and has done valuable service by systematising the subject. We find, however, that, although apparently accepting Professor Leonard Hill's view with regard to vaso-motor paralysis under chloroform and the incidental danger of the collection of blood in the "abdominal pool" so causing cerebral bloodlessness, Dr. Hewitt says (p. 476): "There seems to be very little evidence that the sitting position is of *itself* a danger in chloroformisation provided that the respiration be unembarrassed and the corneal reflex is not completely abolished." This is undoubtedly true if the corneal reflex is not completely abolished, for in that case the "stop-cock action" of the capillaries is still safeguarding the circulation, but we think that Dr. Hewitt's caution that the sitting posture should be avoided in chloroformisation is weakened by the concluding words of the paragraph which we have quoted. We say this in no carping spirit, but as the result of our experience that it is most important to be dogmatic on general principles, and we contend that only the most experienced of chloroformists can be relied upon to conduct a chloroformisation except under the most favourable conditions. Dr. Hewitt's book, as a whole, is a valuable one; good as was the first edition, the present one is better. It has been enriched by a larger experience, the experience of a man who has lost few opportunities of learning from his cases and studying his results, and we congratulate him upon his work.

Pernicious Anæmia, its Pathology, Septic Origin, Symptoms, Diagnosis, and Treatment. By WILLIAM HUNTER, M.D. Edin., F.R.C.P. Lond., F.R.S.E., Senior Assistant Physician to the London Fever Hospital; Joint Lecturer on Practical Medicine, Pathological Curator, and late Pathologist, Charing Cross Hospital. With Plates, Charts, and Illustrations. London: Charles Griffin and Co. 1901. Pp. 480. Price 24s.

DR. WILLIAM HUNTER, having made a prolonged study, extending over 15 years, of pernicious anæmia in all its aspects, may fully claim a right to be considered an authority on the subject, yet in this work we find a strange mixture of certainty and hesitation—certainty in the results of his extensive and painstaking investigation, but hesitation in exactly determining the etiology of the condition concerning which he is writing with exhaustive intent. The impression (it may be a false one) we received after reading the book was that Dr. Hunter would like to assign cario-necrotic conditions of the teeth as the sole cause of pernicious anæmia, but is afraid to do so on account of the obvious question, As dental necrosis is so common, if it be the cause of pernicious anæmia, how is it that the latter condition is so rare? In fact, Dr. Hunter himself remarks: "Dental cario-necrosis is far too common to be itself the cause of so rare a disease as pernicious anæmia." Yet further on he says: "Pernicious anæmia is a chronic infective disease. ..... The chief source of the infection is oral sepsis, arising in connexion with long-continued and neglected cario-necrotic conditions of teeth"; then he still further weakens his argument by adding, "Sometimes, possibly, arising from other causes—e.g., drain poisons." It is true he acknowledges it to be a "special infection of the digestive tract," but the contrast between such statements as the above is confusing, and we are forced to the opinion that Dr. Hunter would have acted more wisely by deferring coming to the above conclusions as to the etiology of the disease until he had examined more cases, for apparently 12 cases only were observed by himself. He also lays too much stress upon the statements of patients themselves as connecting the dental condition with the general condition. Dental cario-necrosis will, as is generally known, cause glossitis and general gastric and intestinal troubles, partly due perhaps to direct infection from the teeth and largely, no doubt, to the defective manner in which the food is masticated.

Dr. Hunter makes a strange statement when dealing with the bacteriology of dental caries. He says: "On this point—the infective nature of dental caries—I need not dwell." Now, we should have imagined that from his point of view—viz., that the infection arises from dental caries—nothing could be of more importance than a thorough investigation of the micro-organisms found in connexion with the teeth. He refers to the acknowledged fact that the pneumococcus is frequently found in the mouths of healthy people, yet under certain circumstances the organisms take on a malignant action and an attack of pneumonia is the result. If he means to suggest that a similar course of events occurs in connexion with pernicious anæmia we should consider this a very plausible theory. Dr. Hunter's observations on Dental Disease as a Cause of Septic Gastritis and his remarks on the Nature of the Infection of Pernicious Anæmia are rather vague and in marked contrast to the decided manner in which he discusses the pathology of the disease and the nature of hæmolysis. He designates the infection as "most probably of a 'mixed' character," and also states that "one element in the infection is streptococcal. ..... Such infection the more readily occurs if the stomach or intestine is already from any cause the seat of disease; the most potent antecedent cause is 'septic' gastritis arising in connexion with oral sepsis." Such statements as these, in which "oral sepsis" is in one sentence stated to be the "chief source" of infection and in another as an "antecedent cause" producing a condition which enables the "chief source" to produce its pathogenic action, are confusing and make the etiology most involved. The bacteriological and pathological conditions must be further investigated to ascertain their relative dependency on each other before we can accept Dr. Hunter's theory as he now presents it; or as he himself expresses it: "It must remain for future observations to determine the nature of the organisms concerned and their relative rôle."

If we consider the author's investigations as to the etiology of pernicious anæmia as incomplete we can speak in the highest terms of approbation as to his investigations on hæmolysis, which are some of the most elaborate and instructive yet carried out; and his conclusions regarding the pathology of the disease are the result of prolonged and patient observation. With regard to the morbid anatomy of the disease he maintains that "none of the pathological conditions—e.g., malignant disease, atrophy of the stomach, gastro-intestinal lesions, &c.—occasionally found associated with the features of pernicious anæmia can be rightly regarded as the essential anatomical lesion underlying the anæmia present, or as reasonably accounting for the remarkable degree of its anæmia as compared with that of all other forms of anæmia." This conclusion is based mainly on two considerations—(1) that similar anatomical changes, often far more marked, are constantly to be met with in cases presenting none of the features of pernicious anæmia; and (2) that still more frequently cases of pernicious anæmia are met with without any such anatomical lesions. Dr. Hunter then proceeds to discuss the changes in the blood and blood organs, pointing out the interesting fact that the rich hæmoglobin colour of the spleen always contrasts markedly with the bloodless condition of all the other organs and tissues with the single exception of the bone marrow. He also shows that in pernicious anæmia the hæmolysis differs in important respects from that occurring in health, and cannot be regarded merely as an exaggeration of the normal process. The most important point in this connexion is that the hæmolysis is confined to the portal area, and inasmuch as gastro-intestinal influences are those which, even in health, specially determine the occurrence of hæmolysis Dr. Hunter considers that it is reasonable to conclude that the conditions that determine the hæmolysis in pernicious anæmia are also situated within that tract—moreover, "that they are of a special character." This last conclusion we have already commented on.

The symptoms of pernicious anæmia are described in an interesting manner and the treatment as based on Dr. Hunter's theory is duly considered, stress being naturally laid on the hygiene of the teeth and mouth, but he very rightly urges that such measures as may prevent or remedy oral sepsis should not replace, but should be supplemented by, the use of arsenic. The part of the volume devoted to the Physiology of Blood Destruction (Hæmolysis) is well worthy of careful study. His experiments in regard to this process have been carefully carried out and demonstrate that the spleen is the chief seat of hæmolysis, the liver being less important, its rôle being mainly that of an excretory organ. Second only in importance to the spleen, the gastro-intestinal capillary area is the chief seat of hæmolysis. Dr. Hunter's reasons for coming to these conclusions are clearly demonstrated. We have not been able to agree with the whole of Dr. Hunter's arguments and consider that portions of his investigations—especially in reference to the etiology of pernicious anæmia—are incomplete, but we do not wish to detract from the value which his work possesses. He has added greatly to what was previously known as to the nature of the disease; in fact, he has been one of the first to establish it as a separate disease, in no way connected with other forms of anæmia, and has shown it to be in all probability a toxæmic condition. We trust that he will carry his investigations further so as to be able to isolate definitely the organisms on which it is dependent.

Vorlesungen über die Pathologische Anatomie des Rückenmarks. (Lectures on the Pathological Anatomy of the Spinal Cord.) By Dr. HANS SCHMAUS, with the coöperation of Dr. SIEGFRIED SACKI. Wiesbaden: J. F. Bergmann. 1901. Illustrated. Pp. 600. Price 16s.

THIS large and exhaustive treatise, which deals exclusively with the pathological anatomy of the spinal cord, affords eloquent testimony to the industry and genius of modern neurologists. It is hardly a hyperbole of speech to say that three-quarters of the facts which go to make up the monumental contents of this book had not been discovered 20 years ago, and that for the most part their discovery has been rendered possible by the vast improvements in histological technique which we owe to Weigert, to Golgi, to Marchi, and to Nissl. The illustrations which adorn the pages of this work are among the finest examples of reproduction with which we are acquainted.

Although the story of the neuron is but a matter of recent history it has proved so complete and satisfactory a basis for the understanding of what were previously little better than pathological conundrums, that the doctrine of these independent cell systems has become practically an article of neurological faith. It will come, therefore, as a matter of surprise to many of us that Dr. Hans Schmaus should be at pains to explain his reasons for accepting this doctrine as the anatomical basis of his neuro-pathological arguments. Although Golgi himself has all along maintained his belief in the probable continuity of contiguous neuronic systems by means of an anastomotic network of fine fibrillæ, this belief has not been shared by the majority of workers in this field of pathology. The view almost universally held has been that the connexion between different neurons was one of contact only and that the nerve-cell exercised a controlling influence over the entire neuron with which it was associated. However, according to the recent researches of Apathy, there seems reason for believing that, at least in the case of certain of the lower animals, the axis-cylinders of nerves are composed of primitive fibrillæ floating in a more or less fluid medium, and that the final ramifications of these fibrillæ or telodendrites are woven into a variety of anastomotic network (*Netzwerk*, *Gitterwerk*, or *Elementar-gitter*) not only in the substance of the nerve-centres but in the ganglion cells themselves (neuropile).

Although up to the present we are in want of actual demonstration that the same histological arrangement holds good in the case of man, Nissl has commented on the considerable hiatus which exists in our knowledge concerning the elements of which the grey substance of the brain and spinal cord are composed, and has ventured on the speculation that the unknown elements may consist of the terminal filaments of primitive fibrillæ woven into an anastomotic neuropile of the same character as that described by Apathy in the case of lower animals. And, further, the controlling influence of the nerve-cell, except as regards its trophic functions, has been called in question by Bethe. By a very delicate manipulative process he has convinced himself that in the case of a crab (*Carcinus mœnas*) reflex actions can occur without the intermediate influence of the nerve-cell, and to the neuropile he relegates this important function. After a very careful consideration of the evidence on which the above hypotheses are based Dr. Schmaus has elected, with all reservation, to abide by the orthodox conception of the independence of separate neurons and the central administration of the nerve-cell. Pathologists will, however, read with the greatest interest the able summary which the author supplies in Lecture II. of the views which threaten to assail the anatomical foundations of modern neuropathy. The significance of the "Nissl bodies" in the life-processes of the nerve-cell are dealt with at considerable length. The process of chromatolysis, whereby the stainable matter disappears, is not regarded as being associated with any specific influence in the determination of disease; it may occur as the result of totally distinct exciting causes, and in various degrees in a great variety of pathological and physiological conditions: it is to be regarded not as a degenerative process *per se*, but as a reaction condition (*Reaktionzustand*) of the nerve-cell. In accordance with the suggestion by Lenhossek the names "tigroid" and "tigrolysis" are respectively adopted throughout this work for the colouring matter of which the "Nissl bodies" are composed and for the process whereby it disappears. These modifications in the nomenclature will obviate many of the ambiguities and misunderstandings which were involved in the use of the terms "chromatin" and "chromatolysis." The consideration of tabes dorsalis occupies three lectures and nearly 100 pages. As a type of a nervous system degeneration which offers the widest scope for discussion the space which is devoted to this subject cannot be grudged. The condition which gives rise to this variety of degeneration is regarded as an elective toxæmia which acts directly upon the intra-medullary fibres in conjunction with other coöperating etiological factors, such as nerve-strain, cold, traumatism, &c. With regard to the possibility of an initial lesion of the ganglion cells of the posterior roots being able to give rise to organic changes in the terminal nerve filaments in the posterior columns, when no demonstrable organic change is present in the ganglion cells themselves, Dr. Schmaus suggests that the conception of a functional disturbance of the nerve-cell leading to degeneration of its most distant process-endings is not altogether incompatible with what we know of cell pathology. The application of Edinger's "adequate nutrition" theory (*Ersatztheorie*) to the pathogenesis of tabes, as well as to that of certain trade palsies, is suggestive and to the point.

The distinctions between atrophy and degeneration on the one hand, and between degenerations and inflammatory processes on the other, which have recently been exposed to the destructive criticisms of most enlightened pathologists, have once again to run the gauntlet of a very severe analytical examination on the part of Dr. Schmaus. We gather that he is inclined to the view that such distinctions as have been attributed to these processes must properly be regarded as distinctions in degree and not in kind. In conclusion, we can only hope that much of the extremely valuable information contained in this volume will, through the medium of our lecturers on pathology, filter through to the rank and file of the profession in this country.

The Twelfth Annual Report of the Asylums Committee of the London County Council for the year ending March 31st, 1901. With Graphic Charts and Statistical Tables London: P. S King and Son. Folio, pp. 188. Price 2*s*.

IN this valuable document, issued by the London County Council, with its wealth of facts and figures concerning London's pauper lunacy, we are informed that the total number of pauper lunatics in the county of London on Jan. 1st, 1901, was 21,369, showing an apparent reduction of 24 on the corresponding number for Jan. 1st, 1900 This apparent diminution is partly due to the recent incorporation of the hamlet of Penge in the county of Kent, thus relieving the county of London of 50 pauper lunatics, and partly to the removal of 124 patients in the London county asylums originally classed as paupers to the class of "private" patients. Allowing for these circumstances the original figures represent an increase of 150 lunatics during the year. Besides, "certified lunatics" the above returns include all lunatics in workhouses and "with relatives or friends." Limiting consideration, however, to pauper lunatics under reception orders (this being the class for which accommodation has to be found in the London county asylums), the total number on Jan. 1st, 1901, was 15,274, being an increase for the year of 213. "During the 11 years the Asylums Committee has had the control of the asylums there has been an increase of 5174 certified pauper lunatics. ...... As the 1901 census figures for London have just been published it is possible to give the ratio of lunatics to the population [in 1901] as compared with 1891, and this shows that there is an increase in the ratio of pauper lunatics to the population." Thus the ratio of "certified" pauper lunatics in January, 1891, was 2·467 per 1000 of population of the county of London (excluding the City), and in January, 1901, it amounted to 3·389 per 1000. The ratio of all pauper lunatics, whether certified or in workhouses or in the care of relatives, in January, 1891, was 3·940 per 1000 of population, and in January, 1901, it amounted to 4·739 per 1000. These facts comparing the increase of lunacy with that of the population are graphically shown in a coloured chart. The normal capacity of the existing asylums has been of late utilised to the utmost and there yet remain 1283 patients in excess of the accommodation at the date of the report. To meet this and future increases an asylum at Horton for 2000 patients is in course of construction and an epileptic colony for 300 male patients will shortly be commenced. Meanwhile temporary buildings put up five years ago at Colney Hatch and Banstead for the accommodation of 600 patients (300 females and 300 males) have been occupied under the sanction of the Home Secretary, and a further extension of time for another five years has been applied for and allowed. The building of the new asylum at Horton Manor is progressing satisfactorily, and 110 male patients are now located there in a temporary annexe to the main building. The Council recently approved of the provision of a working colony for 300 insane male epileptics on the Horton Estate and sanctioned a sum of £89,000 for carrying out the plans, and after consultation with the Commissioners in Lunacy it was finally decided that villas on the single floor plan should be built. Suitable plans were prepared, and they received the sanction of the Commissioners in Lunacy in November, 1900, and the sealed approval of the Home Secretary in April, 1901.

The recovery- and death-rates of the patients in the county asylums are given in Table I. of the Report. From this it appears that during the year 218 patients were discharged as "recovered" from Hanwell Asylum, 242 from Colney Hatch, 238 from Banstead, 150 from Cane Hill, 213 from Claybury, 175 from Bexley Heath, and 45 from Horton Manor Asylum The total number of recoveries thus amounted to 1281, or 9·02 per cent. of the average number of patients resident in the London county asylums. The deaths during the year amounted to 232 at Hanwell, 212 at Colney Hatch, 247 at Banstead, 190 at Cane Hill, 233 at Claybury, 165 at Bexley Heath, and 43 at Horton Manor. The total deaths thus amounted to 1322, or 9·31 per cent., calculated on the same basis. It will be seen from a consideration of Table III A. that the recovery-rates varied considerably for different asylums. Thus, at Horton Manor it was 6·56 of the average number resident, at Cane Hill it was 6·77, at Claybury 8·53, at Hanwell 8·66, at Colney Hatch 9·52, at Banstead 9·74, and at Bexley Heath 13·53 Leaving out the first and last institutions, which are both of recent origin and in which the recovery-rates show the lowest and the highest figures respectively, the five older (and larger) asylums show a variation in the recovery-rate from 6·77 (Cane Hill) to 9·74 (Banstead), which is difficult to apprehend except on the supposition that the term "recovery" has, as regards insanity, no hard-and-fast demarcation, and is differently construed by different authorities. The death-rates, however, show a remarkable uniformity throughout the asylums, being 8·3 per cent. at Colney Hatch, 8·5 at Cane Hill, 9·2 at Hanwell, 9·3 at Claybury, and 10·1 at Banstead, the mean death-rate being 9·3 for all the asylums.

The weekly cost of the maintenance per head during the financial year 1899-1900 was 10*s.* 1½*d.*, but as this was insufficiently met by the weekly charge to the unions and parishes of 9*s.* 11*d.* per patient, it became necessary to revise the latter, and in view of the increased prices of coals, provisions, and stores the charge has been raised to 10*s.* 9½*d.* per week as from July 1st, 1901.

An interesting and concise report of the work done at the pathological laboratory at Claybury is appended by Dr. F. W. Mott, the director. The work includes investigations in neuro-pathology and the pathology of insanity. A small department with apparatus for psycho-physical measurements has been placed under the charge of Mr. W. G. Smith, M.A., Ph.D. of Leipsic. A second volume of the "Archives of Neurology" will shortly be published which will contain the record of the work done in these departments. The Report on the whole is a weighty document, showing how large and important is the question of lunacy for London and the nature of the social and financial burden which it entails on the community.

Gynæcology: a Manual for Students and Practitioners. By MONTGOMERY A. CROCKETT, M.D. Series edited by BERN B. GALLAUDET, M.D. Illustrated with 107 Engravings. London: Henry Kimpton. 1901. Pp. 368. Medium 8vo. Price 7*s.* 6*d.* net

IN this book Dr. Crockett has endeavoured to reflect the accepted views of the foremost authors and practical gynæcologists as expressed in the rich standard literature of the subject. He has succeeded in producing a book which undoubtedly does give a fair view of the present conditions of gynæcology. The space devoted to the various subjects is well proportioned and there is no unnecessary detail. The tendency to over-estimate the importance of minor gynæcology and local applications is not yielded to by the author who rightly points out that "there are a few cases of uncomplicated metritis which may be benefited by local applications, but they are so few that womankind as a whole would be the gainer were topical application within the uterus utterly abolished except in connexion with the operation of dilatation and curettage." A good and practical account is given of the uses and mode of application of the vaginal tampon—a useful means of treatment with which students are often somewhat unfamiliar. Dr. Crockett holds that the routine method of disinfecting the vagina must be severely criticised if it be judged by the results of Whitridge Williams's work upon the bacteria of the genital tract. Part of his argument—viz., that after labour healing takes place more favourably if internal disinfection be omitted—hardly holds good. It must be remembered that the passage of the child's head tends to obliterate all the vaginal folds and the escape of liquor amnii washes out very effectually the whole of the lower genital tract. There is nothing at all analogous to this natural cleansing in the case of a patient who is to have an operation performed upon the uterus or vagina. We are glad to see that in discussing the treatment of chronic metritis and chronic pelvic peritonitis the author lays stress upon the importance of treating the general health of the patient. The value to the patient of conservative measures in operations upon the ovaries is very great, and we are fully in agreement with Dr. Crockett when he says, "There is developing such an array of clinical facts in favour of conservative gynæcology that the surgeon who as a routine practice removes tubes and ovaries is now put upon the defensive and must show cause why he is not open to severe criticism." On the whole, a book we may safely recommend for the use of students.

LIBRARY TABLE.

Brief Notes on the Outbreak of Plague in the Jammu Province, Kashmir State, during 1901. By B. R. SAWHNEY, M.B., B.S. Durh. Jammu, 1901. Pp. 21.—In this pamphlet Dr. Sawhney, Chief Medical Officer, Jammu Province, gives a detailed account of the spread of plague in 16 villages having an aggregate population of 7620, among whom there were 489 cases of the disease with 329 deaths between Feb. 27th and June 11th, 1901. In the largest of these places, a town called Samba, with 2618 inhabitants, popular feeling was so much opposed to the measures adopted for limiting the spread of the epidemic that all official interference had to be suspended. In one of his statistical tables Dr. Sawhney shows that the proportion of persons attacked and also the duration of the epidemic were much greater in the villages in which the people had to be left to themselves than in those where preventive measures were adopted officially.

Shanklin Spa: Its History and Guide to the Town and Neighbourhood. By "MONOPOLE." Shanklin: Silsbury Brothers. 1901. Pp. 150. Price 6*d.*—This little book describes the Shanklin Spa at which comparatively recently an installation of warm ferruginous baths has been established on the same principle of the iron baths at Spa and Schwalbach. It is profusely illustrated and the illustrations are pleasing and artistic. "Monopole" is enthusiastic in favour of Shanklin as a health resort and he certainly has strong argument in favour of his case. It is stated in the preface that some change will be made in the next edition when the report of the Special Commissioner of THE LANCET[1] on the chalybeate water will be inserted. Intending visitors to Shanklin and to the charming scenery of its environment will find this little book of interest, and we should not be surprised if "Monopole's" example were followed by writers resident in other health-resorts.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., with the coöperation of ADAM SEDGWICK, F.R.S., W. F. R. WELDON, F.R.S., and SYDNEY J. HICKSON, F.R.S. With Lithographic Plates and Engravings on wood. London: J. & A. Churchill. 1901. New series, Vol. XLIV., Part 4 (price 10*s.*), and Vol. XLV., Part 1 (September, pp. 88, price 10*s.*).—The articles contained in Part 4 of Vol. XLIV. are as follows: 1. On Two New Species of Onychophora from the Siamese Malay States, by Richard Evans, M.A., B.Sc., of Jesus College, Oxford. Mr. Evans was fortunate enough to obtain 13 specimens of Peripatus, two of which—both females—he has named Eoperipatus Weldoni and 11 of which—six males and five females—are named Eoperipatus Horstii. The first specimen, he says, was brought to him by a Malay who carried it between the prongs of a split stick. On handling the animal it suddenly squirted upon Mr. Evans a whitish sticky slime to a distance of fully 18 inches. His hands were covered with it, and though it did not stick to the body of the animal itself he only succeeded in getting it off with much difficulty. This slime, though fluid when first exuded, solidifies almost immediately and whilst semi-solid can be drawn out into threads like the juice of the rubber tree. A very detailed description is given of both species and six plates with many figures accompany and illustrate the article. 2. A second article by Mr. R. Evans, supplementary to the foregoing, gives a description of a single female of a new species sent to this country by Mr A. M Butler, curator of the museum at Selangor Straits Settlement, which Mr Evans has named Eoperipatus Butleri. The details of the structure of this species are given in a plate 3 On Two New British Nemerteans, by R C Punnett, B A., with two plates These animals were found by Mr Punnett whilst digging in the mud of the river Yealm at low water mark. He has named one of the species Micrella rufa, which belongs to the family of the Lineidæ, and the other Oxypolia beaumontiana, which belongs to the family of the Eupolidæ. Two plates illustrate the dissection of these animals 4 The Coelomic Fluid in Acanthodrilids, by W Blaxland Benham, D Sc, with a plate Dr Benham finds that in addition to amœbocytes there are "eleocyte" cells or cells containing refringent oily globules There are also some curious thread containing cells or linocytes, and lastly large rounded cells with a distinct pedicle without pseudopodia. The cytoplasm is occupied in these cells, which he names lamprocytes, by numerous vacuoles, each of which usually contains a small, highly refringent granule The lamprocytes are the most abundant of the four forms of corpuscle 5 The Crystalline Style of Lamellibranchia by S B Mitra of Calcutta The style is pronounced by Mr Mitra to be in reality a secretion, a digestive ferment whose function it is to digest starch—i e to convert starch into a reducible sugar The structure of the style is given in a plate This part of the *Quarterly Journal of Microscopical Science* contains the table of contents and the index of the forty fourth volume of the new series —Part 1 of Vol XLV contains two memoirs The first is by J Graham Kerr on the Development of Lepidosiren Paradoxa, with a note upon the corresponding stages in the Development of Protopterus Annectens illustrated by four plates The author shows that the earlier stages of the development of the protopterus closely resembles that of lepidosiren He remarks that the contradictory statements to be found in the accounts of the development of these and other animals given by distinguished observers are due in part to insufficiency of material and in part to differences in the methods of preparing specimens for section and in their subsequent treatment The second memoir is by Richard Evans, M A., B Sc, of Jesus College Oxford, on the Malayan Species of Onychophora, dealing especially with the Development of Eoperipatus Weldoni The article is illustrated with five plates

[1] THE LANCET, Oct. 6th, 1900, p. 1029.

The *Practitioner* for September continues the discussion of Fractures Mr John Poland contributes a comprehensive article on Separation of the Epiphyses which is very well illustrated, including some good reproductions of skiagrams Fractures of the Spine and their Treatment are dealt with by Mr C A. Morton, who takes on the whole a view very unfavourable to operation in the remedying of these injuries His opinion is that in the vast majority of the cases the chief damage is that done to the cord at the time of injury which is unaffected by subsequent operation In this connexion the little value of skiagrams, as showing nothing of the injury of the cord, is remarked upon. The rare cases in which there is fracture of the arch alone are by far the most hopeful ones for operative treatment Dr C H Bond writes on Fractures in the Insane, showing their frequency to be due to nutritional bone-changes giving to the bones a much diminished breaking strain The review of Infectious Diseases contains an account of researches as to the etiology of small pox that will be read with interest at the present moment. Definite peculiar corpuscular elements have been observed in variolous pus, but the interpretation of their significance is at present different at the hands of different observers

Progressive Medicine Vol II June, 1901 Edited by HOBART AMORY HARE, M D, assisted by H R M LANDIS M D London Henry Kimpton 1901 Pp 470 — The list of contributions to the June number of this quarterly is a short one, and therefore may not inappropriately be mentioned at length The first is by Dr W B Coley, and deals with the Surgery of the Abdomen. The second is on Gynæcology and is from the pen of Dr T. G Clarke The third and fourth are contributed by Dr A Stengel and Dr E Jackson respectively, and supply the latest information with regard to the Diseases of the Blood and the Surgery of the Eye In addition to a general review of the most important developments in abdominal surgery, Dr Coley has selected as a subject for special discussion the Surgical Treatment of Malignant Disease of the Stomach and Bowels This affords him an excellent opening for dealing generally with recent advances in the methods of intestinal suturing, and particularly with the "Connell method" of end to end anastomosis and the Lee holder, a most convenient instrument for maintaining the intestine in position during the operation In this section also a full account is supplied of the indications for surgical interference in cases of suspected perforation during the course of typhoid fever Dr Osler's recent and important paper on this subject[1] is carefully abstracted and his schedule of instructions for house physicians with regard to the diagnosis of this complication is given at length To prove how useful such a schedule may be in the hands of intelligent medical officers it may be mentioned that at Dr Osler's own hospital 11 cases of perforation had been surgically treated up to January, 1901, with five recoveries The chances of successful surgical treatment of course largely depend on the celerity with which the diagnosis of perforation is made by the attending physician Dr Clarke prefaces his article on Gynæcology with an account of Leopold's blastomycetic theory of cancer, a little further the subject of enteroptosis is considered chiefly from the pathogenetic point of view of weak abdominal walls and relaxed pelvic floor The author also describes at length Kelly's modified operation for the removal of the uterus, uterine tumours, and appendages by his "bisection method" The value of pain in the diagnosis of diseases belonging to this department is also fully discussed Dr Stengel's contribution which is the only one which deals with medical subjects occupies about 80 pages and is all too short The examination of the blood as a help to diagnosis together with an account of several improvements in method and technique occupy the first 15 pages of this section. For the rest anæmia hæmophilia scurvy, diabetes, and gout represent the chief diseases which deserve to be included among those which may be said to have "progressed." In the article on Ophthalmology although it is an excellent summary of recent improvements in eye surgery, there is nothing to arrest the reader's attention with the exception of an account of the retraction movements of the eyeball in certain congenital conditions of maldevelopment of the extrinsic musculature of the eyeball

New Inventions.

THE TWIN ICE BAG

THE twin ice bag represented in the accompanying illustration is intended for the application of ice to the thorax or abdomen of restless patients and has been made according to my instructions by Messrs Arnold and Sons of West Smithfield London E C It is made entirely of plain rubber, straps included and is thereby not injuriously acted upon by the secretions from the body Having given it a good practical trial I have found it to give complete satisfaction and I can confidently recommend it to the profession. The advantages I claim for it are as follows :—1. In its application to the thorax, back or front; restlessness of the patient does not interfere with its perfect action. The ice or ice water, owing to the two separate compartments, cannot gravitate from the side on which it is required to act. It can be emptied or filled with very little disturbance to the patient if the nightdress is put on so that its opening corresponds to the seat of the ice-bag—namely, on either the anterior or posterior surface of the body. On loosening the shoulder straps (not interfering with the waistband) whilst the patient lies on his side and allowing the upper portion of the bag to hang down, removing the stopper, and slightly pressing on the bag, the contents can be emptied into a dish and the bag refilled with a minimum of disturbance to the patient. If the patient is not too ill to sit up in bed it will be easier still to empty and fill the bag. The openings in the bag are so placed that they are very unlikely to press on the patient, but if they happen to do so they are within such easy reach of the patient that he can place them just where he likes. The application of ice in pneumonia I believe to be the most satisfactory treatment, especially from its effect in controlling the temperature. 2 In its application to the abdomen, as will be seen, the shoulder straps can be made use of round the thighs, and the ice-bag in this situation has all the advantages claimed for it in its application to the thorax. On the abdomen it is not only useful in cases of inflammatory troubles situated in this cavity, but also as a general temperature reducer I have found it to act very beneficially. I see no reason why this bag should not be applied to the head as well in cases of refractory patients, using the arm straps under the armpits and the waistband under the chin.

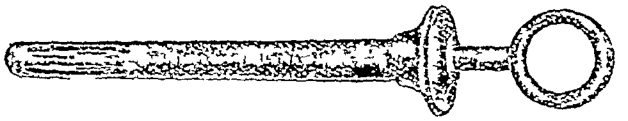
MARTIN J. CHEVERS, L.R.C.S., L.R.C.P. Irel.
Huddersfield.

NEW FORM OF OINTMENT CARRIER FOR THE RECTUM.

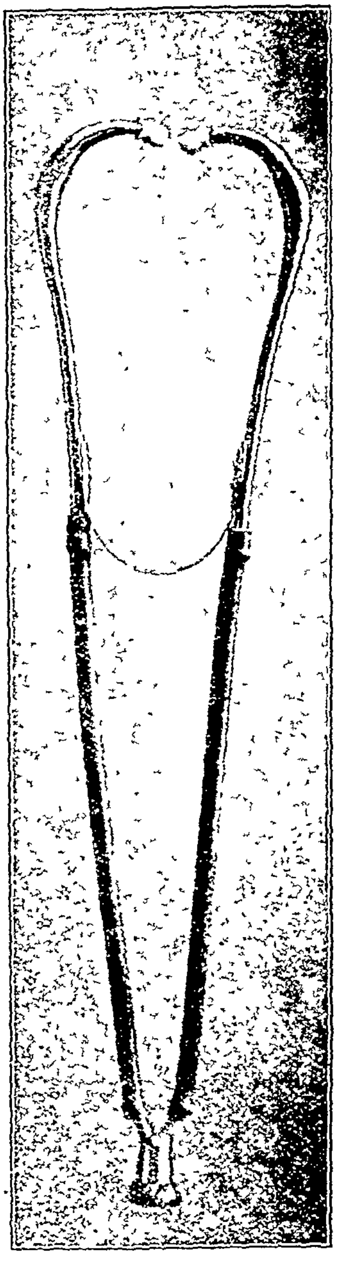
THE various forms of ointment carriers (rectal and otherwise) are, I consider, made on a wrong principle, being fed from below. When such instruments have been used and then left for some time till required again, it will be found a difficult matter to get them to work, the ointment left after previous use having become hard and dry. The form depicted in the illustration and made for me by Messrs Arnold and Sons of West Smithfield, London, E C., gets over the difficulty completely. The point is to be dipped into the ointment receptacle and then rotated while the piston is being withdrawn, when the cage at the top will be filled, and if the instrument is then introduced into the bowel and the piston pushed home all the ointment will be extruded and none left to block the tube when required for use again. The openings at the point are much larger than usual, which is another advantage, for in the older form the small perforations became completely plugged after one using. The simplicity and saving of time by the use of the form of ointment carrier now described should ensure its universal adoption.



ALEXANDER DUKE, F.R.C.P. Irel.
Cheltenham.

A BI-RESONATING STETHOSCOPE.

I HAVE devised this instrument with a view of intensifying and rendering more distinct the sounds which the auscultator is accustomed to listen for when examining a patient. As seen from the illustration, the stethoscope is a simple one no complex mechanism being brought into its formation, thus avoiding any danger of the production of accessory sounds, which might be produced by the friction of a complex mechanism. The difference between my instrument and those that are already used for the same purpose is that in others there is only one resonating chamber and that is placed against the chest wall, or in very close proximity. In my instrument it will be observed that there are two resonating chambers, and that they are placed in close apposition to the ear-pieces. The advantage of the above arrangement is that the various sounds are conveyed up the almost straight tubes and enter the resonating chambers; there they are intensified and the impressions are conveyed direct to the ears and have not to travel through any tubing after being so rendered more distinct. Another great advantage in this instrument is that by the position of the resonating chambers the sounds have the impression to the auscultator of being very much nearer, thus some of the minutest sounds are comparatively easily heard and detected and no buzzing noise interferes while using the instrument The instrument is light in weight and compact, being similar to that of the ordinary stethoscope. The spring is fixed on to the tubes by means of an additional plate, thus the lumen of the tubes is in no way interfered with



Any chest-piece can be used with this instrument, but the one I find best is of simple construction and is dome-shaped, as seen in the illustration. The instrument has been made for me by Mr. A. Schollar, instrument maker, 64, Praed-street, London, W., and the complete cost is 12s. 6d

FROM

THE LANCET LABORATORY.

(1) MAMESIN; AND (2) MA.ME CO.

(THE MYOSIN ALBUMIN MEAT EXTRACT COMPANY, 107, STRAND, LONDON, W.C.)

LIEBIG long ago admitted that meat extracts possessed but feeble if any real nutrient property at all, and it is regrettable that Liebig's conclusions, which were correct in every detail, are not more seriously regarded than they are. The bulk of meat extracts at the present day only represent the actual nutritive value of meat to a very limited degree. The real essence and nourishing portion of meat is the albumin of the muscle which is readily digested, readily absorbed, and readily appropriated Yet most commercial methods reject, if not altogether, certainly the greater part of, this powerful nutrient material. We therefore recognise in the preparations before us an important advance, for they both contain myosin albumin in a proportion exactly adapted for nutritive requirements. The albumin is extracted by an ingenious and physiologically sound process which at the same time is simple enough in detail to admit of the product being sold at a moderate cost. Ma.Me.Co., to describe it as simply as possible, is wet myosin albumin. Its proximate composition is as follows: water, 86·04 per cent.; mineral matter, 0·66 per cent.; and meat derivatives, 13·30 per cent. The albumins amounted to 12·46 per cent., equal to 1·99 per cent of nitrogen, and the meat basis amounted to 0·30 per cent., equal to 0·01 per cent. of nitrogen, while fat was present to the extent of 0·54 per cent. The total nitrogen was thus 2·00 per cent. Mamesin differs from Ma.Me.Co only in containing besides myosin albumin the extractives and gelatines of beef. *Its proximate analysis was as follows:* water, 81·24 per cent.; mineral matter, 3·21 per cent.; and meat derivatives, 15·55 per cent. The total amount of albumin was 11·73 per cent., equal to 1·87 per cent of nitrogen, while the meat bases amounted to 3·27 per cent, equal to 0·79 per cent. of nitrogen, and the fat to 0·55 per cent. The total nitrogen was 2·66 per cent., of which nearly three-fourths are contained in myosin albumin. The preparations readily peptonise, giving quite clear solutions of peptone. An important feature is the entire absence of fibroid matter or similar insoluble nitrogenous stuffs of meat which are difficult of digestion. Thus while both Mamesin and Ma.Me Co. are practically equal from a nutritive point of view, weight for weight, to meat, they obviate any difficulty of digestion arising from the presence of meat fibre. Mamesin is tasteless, while the taste of Ma.Me.Co is of a pleasant beefy character. Both preparations are contained in tins and we could not find the slightest evidence of any action upon the metal having taken place; it was bright and without any signs of corrosion We also searched for chemical preservatives but without any evidence of their presence. The preparations are a very obvious advance on many so-called meat extracts; they present the actual albumin of meat, which is easily absorbed, sustaining, and powerfully nourishing.

AROMATIC IRON MILK (DOLLE BREMEN).

(A. STRAUSS COLLIN, BUSH LANE HOUSE, CANNON-STREET, LONDON, E C.)

This is a somewhat remarkable preparation In appearance it is exactly like milk, but on analysis we found it to consist of a liquid containing pyrophosphate of iron in suspension, associated with spirit, glycerine, and sugar, and certain aromatics. "Iron milk" certainly does not present the appearance of a preparation containing iron, being quite white, while it possesses no taste except that of aromatics and has no astringent effects. We found the preparation to contain 1·12 per cent. of ferric oxide, which is equivalent to 2·9 per cent. of anhydrous ferric pyrophosphate. Of course, the preparation does not affect the teeth because the iron is in an insoluble form until it reaches the gastric organs. It is an excellent means of administering iron, pleasant to take, and free from medicinal taste. Having regard to the fact that the iron is associated with phosphorus the preparation is calculated to exert marked tonic effect. We could find no objectionable preservatives in it. In German clinics "iron milk" is spoken of as a very satisfactory means of exhibiting iron and as free from the objectionable disturbing effects often set up by ferruginous preparations.

SINARO NATURAL TABLE WATER.

(LONDON OFFICES, 29, ELY-PLACE, HOLBORN, E C.)

On analysis Sinaro shows only a moderately saline composition. The chief saline ingredients are common salt, carbonate of calcium, and carbonate of soda. The amount of salt given in an analysis by Professor Fresenius is considerably below the amount which we found, so that we infer that a small quantity of salt has been added to the natural water to make it more palatable. The total saline ingredients amounted to 2·138 grammes per litre and were comprised as follows: carbonate of soda, 0·55 gramme per litre; carbonate of calcium, 0·74 gramme per litre; and common salt, 0·848 gramme per litre. The water is very agreeable to the taste, bright in appearance, and though pleasantly sparkling contains not a great excess of carbonic acid gas. We could find no evidence of organic impurity. It possesses antacid properties and is a table water of a good description.

CROWN MALT EXTRACT

(THE UNITED BREWERIES COMPANY, LIMITED, COPENHAGEN LONDON OFFICES, 46, QUEEN VICTORIA-STREET, E C)

Malt extract contains chiefly malt sugars and dextrine and potassium salts (mainly the phosphate), while nitrogen-containing substances are not present to any important extent. On analysis the Crown malt extract gave the following results: extractives, 10·51 per cent; mineral matter, chiefly phosphate of potassium, 0·23 per cent; absolute alcohol, by weight 5·81 per cent., by volume 7·25 per cent, equal to proof spirit 12·70 per cent It will thus be seen that the extract presents much the composition of stout, though with its nourishing qualities enhanced and its acid contents reduced to a minimum The extract effervesces slightly and possesses a strong malty flavour. It, however, shows no digestive action upon starch, so that what diastase may have been in it has been rendered inactive, probably by boiling. It presents the nourishing qualities of malt in a concentrated form.

(1) TABLOID SODIUM CACODYLATE, (2) TABLOID HYPODERMIC SODIUM CACODYLATE, AND (3) TABLOID MORPHINE AND EMETINE

(BURROUGHS, WELLCOME, AND CO., SNOWHILL-BUILDINGS, LONDON, E C)

The salts of cacodylic acid are interesting in that they enable a comparatively large quantity of arsenic to be administered in diseases in which arsenic is of known value. The accuracy of dosage is, of course, of great importance and this is secured by the use of tabloids both for administration by the mouth and for hypodermic use. Both tabloids contain a quarter-grain of the pure sodium salt The tabloid morphine and emetine contains $\frac{1}{20}$th of a grain of morphine sulphate and $\frac{1}{30}$th of a grain of emetine—a formula which is designed to be of service as a sedative and expectorant in alleviating irritable cough. The tabloid is to be dissolved gradually in the mouth, where it exerts also demulcent properties.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 28, 1901.

The Local Government Board and Vaccination.

ON Sept. 17th the Local Government Board, in order to strengthen the hands of vaccination officers in the discharge of their duties, addressed to boards of guardians throughout the country a circular containing the opinion of the law officers of the Crown on certain questions which have arisen in course of the enforcement of the Vaccination Acts. This circular deals with some of the defences that have been raised by legal gentlemen defending parents charged with neglecting to have their children vaccinated. These defences have often shown considerable ingenuity and have frequently been successful before paid magistrates as well as before country benches, mainly, no doubt, because the vaccination officer is pitted against a professional advocate, while his own practical knowledge of the law of evidence and of the interpretation of statutes is limited to those cases in which he has been engaged under the Vaccination Acts. The defences to which the Local Government Board calls attention relate to the service, to the proof of the service, and to the contents of two notices which have hitherto played an important part in vaccination proceedings. The first of these notices is the notice which is to be given by a public vaccinator of his intention to visit a child's home in order to offer to vaccinate it, if it has not been vaccinated within four months of its birth. The notice is given under Section 1 (3) of the Vaccination Act of 1898. The second is the notice to procure a child's vaccination referred to in Section 31 of the Act of 1867, which must be given as a preliminary to any proceedings under that enactment. With regard to both these notices it has been urged that they must be served personally on the parent or other person having the custody of the child. The Local Government Board, on the advice of the law officers of the Crown, informs vaccination officers that personal service is unnecessary, and that both these notices may be sent by post in ordinary unregistered letters.

The circular then calls attention to the proper procedure to be followed in issuing summonses under Section 31 of the Act of 1867, intimating that the points to be stated in the information when the summons is applied for are—(1) that the child has not been vaccinated; (2) that the parents have had notice under Section 31; and (3) that the notice has been disregarded. Then it is pointed out that upon the hearing of the summons the only question to be determined is whether the child has or has not been vaccinated, or has already had the small-pox. To the determination of this question it is entirely irrelevant whether the parent had notice that the public vaccinator would come to his house, nor does it matter whether the public vaccinator ever went there and offered to vaccinate the child or not. No evidence, therefore, need be given as to this. Nor is proof of the sending of the second notice (that is, the notice under Section 31 of the Act of 1867, to procure the vaccination of the child) a necessary part of the case for the prosecution. But as it may become so, owing to evidence being given for the defence that no notice was received, or as magistrates may refuse to adopt the view of the law officers of the Crown upon this point, the further opinion is given:—(1) that the service of the notice will be *primâ facie* established by showing that it was sent to the defendant properly addressed, prepaid, and posted; and (2) that the contents of the notice may be proved by verbal evidence without production of original or duplicate documents. At the same time, however, excellent advice is given to vaccination officers as to the best method of keeping accurate record of all notices given, with a view to proving their contents, and with this advice the circular ends. That it was desirable that some such attempt should be made to elucidate the procedure in vaccination cases there can be no doubt. Without multiplying instances we may mention the following. In last November Mr. FORDHAM, sitting at the North London Police-court, allowed two points to be successfully taken by the defendant's advocate, only adjourning the case on the vaccination officer paying £5 5*s.* as costs, and this in order that notice might be given to the defendant to produce the notice given to him of the intention of the public vaccinator to call and offer vaccination. This notice is now declared by the law officers of the Crown to be wholly irrelevant. On the other hand, sitting in South-west London within a short time of this, Mr. R. O. B. LANE, another metropolitan magistrate, took the opposite and, as it now appears, correct view, and held that proof of the service of the public vaccinator's notice was not a condition precedent to prosecution and conviction. If London magistrates who are barristers of experience thus differ among themselves it can hardly be expected that the lay bench will do better; but in future, on these points at any rate, magistrates will only go wrong if they care to decide in the teeth of the opinion of the Attorney-General and Solicitor-General and to risk attention being called to their errors by appeal to the High Court.

The Local Government Board has also addressed a letter to the London School Board in order to obtain if possible the coöperation of the London School Board in dealing with the outbreak of small-pox in the metropolis. The Local Government Board asked the London School Board to accord the same facilities for the examination of children in the schools under its control as have been afforded by the managers of voluntary schools with a view to the protection of the children, and so of the public, by vaccination. In seeking the coöperation of the London School Board in the present emergency the Local Government Board has not been charged with the carrying out of powers to compel. It has rather had to endeavour by persuasion and diplomacy to convince a body—and a body fully alive to its own importance and the strength of its own position—of the urgency of maintaining the public health by all possible precautions. In this it has not been altogether successful owing, no doubt, to the views held by admitted anti-vaccinationists on the School Board and to the fear of arousing unpopularity among their constituents on the part of others. In response to the representations addressed to it by the Local Government Board the School Board passed on Sept. 23rd, after a lengthy discussion and the moving of many amendments, a motion which in its final form was as follows:—

"That facilities be given to the public vaccination officers of the metropolis, on the application of the proper local authority, to enter the schools of the Board in infected areas for the purpose of examining the arms of the children with a view to advising the parents to allow their children to be vaccinated, provided that the School Board issue a circular to the parents of the children asking if they have any objection to that examination, and in case of such objection in any particular case that the said examination shall not take place, and that the Local Government Board and the public vaccination officers be informed accordingly."

On the principle that half a loaf is better than no bread the facilities thus afforded may be accepted by the Local Government Board and by the London public, but it must be pointed out that facilities so hedged round with conditions and qualifications do not amount to much. The steps that may now be taken are not the most effective that the law would have permitted, and will not be sufficient to ensure the safety of the London School Board children as a body from small-pox, while any estimate of the number of vaccinated and unvaccinated children in the metropolis based upon the examination of the Board's children will be untrustworthy. Presumably, parents of vaccinated children will, as a rule, offer no objection to the arms of their offspring being examined by the public vaccinator, and the objectors will be mainly the parents of at proportion of the unvaccinated; but it will not be safe to assume that they are entirely so, while figures based solely on the proportion of vaccinated and unvaccinated among those actually examined would undoubtedly be fallacious. It is to be hoped that the parents—some at any rate—of the unvaccinated will yield to the advice which the London School Board, with great consideration for their prejudices, allows to be administered to them, and that a serious spread of the epidemic will not necessitate the closing of schools on any large scale

On Sept. 25th three more circulars emanated from the Local Government Board, each showing that our official bureau of public health is on the alert to prevent a disastrous spread of small-pox in the capital. The first is a memorandum on the steps specially requisite to be taken by boards of guardians, their vaccination officers, and sanitary authorities in places where small-pox is prevalent The second, a supplement to the first, specially urges upon boards of guardians the value of prompt revaccination, and the necessity of seeing that their vaccination officers immediately take such steps as may be necessary to deal effectively with any arrears in the union or parish. The boards of guardians are enjoined to see that any cases of default are dealt with by the vaccination officers under the Vaccination Order of 1898, and that the addresses of unvaccinated children are ascertained from all available sources; while they are instructed to assist their vaccination officers if there is any difficulty put in the way of a quick performance of their duties The third circular is addressed to the metropolitan borough councils, and asks the councils to specially instruct their medical officers of health to visit without delay all houses where an outbreak of small-pox has been notified, and to take immediate steps for the isolation of the patient and the disinfection of the premises

◆

The Nursing Home.

ONE of the most remarkable developments in medical life of recent years, arising naturally enough as a side issue from the growth of modern surgery, has been the creation and the extensive use of private surgical homes. As the success of surgery became more and more apparent since the introduction of the aseptic principles, so the number of operations performed every year increased enormously. It was not only that operations hitherto believed to be impossible, or unjustifiably risky, or at least inadvisable, were one after another brought within the ordinary list of the surgeon's operative scheme, but also the public became more and more aware that a surgical operation was no longer a dreadful ordeal with a more than doubtful issue, but that it was in many cases a painless experience with a perfectly satisfactory result. Thus an ever-increasing number of persons, particularly of the better-educated and better-off classes, came to seek the help of surgery; and surgeons, anxious to repeat the successes of their hospital experience, naturally enough strove to assimilate the conditions of operations in private to those that had stood them in good stead in hospital work. And so the private hospital and the surgical home became established things. Once inaugurated such institutions soon proved their usefulness to both patient and surgeon Sojourn in them was necessarily somewhat expensive, but on all hands their great convenience was so much insisted upon that to be a patient in one was part of the routine of a surgical patient of some means. Now it may well be questioned whether entry into such a refuge is not sometimes insisted upon when a patient's welfare and comfort would be better consulted if he were to remain at home.

The great advantage which operating in a surgical home originally offered, as opposed to operating in a private house, was that in the former a surgeon secured all those conditions which he considered necessary to success A clean, simply-furnished room, the proper light, plenty of nurses and all the elaborate requirements of perfect antisepsis were at his hand, and in a building near his own home. These were rarely available in a private house. To-day the same does not hold good. We have learnt by experience that surgical cleanliness is more simply guaranteed than was at first thought possible. Antiseptic sprays altogether, and strong antiseptics with many surgeons, are things of the past A steriliser for the instruments, the concentrated form of some chosen antiseptic, and a liberal supply of hot water satisfy nowadays the most exacting surgeon, and allow him to achieve successes rarely attempted and never surpassed a few years ago. He has also learned that there is no safety in a multitude of counsellors, and counting every fresh pair of hands a fresh chance of danger he likes to keep down the number of nurses immediately concerned in the operation to a minimum. There are, too, more well-trained nurses now than formerly, and one of these can rapidly render any bedroom of fair size as favourable an operating theatre for all ordinary proceedings as that of any surgical home. For these reasons, unless the operation has to be done at very short notice, a surgeon who can send his nurse into the house 24 hours before the operation may usually count on success in a patient's residence just as surely as in a nursing home. Moreover, in a private house his nurses are under his own control, whereas in a home it is not unknown for the authority of an ill-trained matron, who is constantly on the spot, to bear adversely upon the directions of the surgeon.

From the patient's point of view to go into a nursing home offers this great advantage, that his own house is spared the inevitable disturbance that an operation demands, as well as the continual inconvenience of harbouring one nurse, if not two or three. The nurses, however, presuming that they are of a kind now happily becoming common, will soon be found to add to the convenience of the household, and the upsetting of the house for the operation will not be of much moment unless it is a very small abode. Unhappily, it is just in these instances that a nursing home is likely to be out of the question for pecuniary reasons, which brings us to a second criticism of the institutions. In spite of the large number of homes there is no doubt need of one, in London at any rate, where patients could be received belonging to that large class who are not suitable for hospital treatment and yet cannot afford the expense of a surgeon's fee, in addition to the hotel charges during the long period necessarily passed in a surgical home if the operation is one of any severity. Except the saving of inconvenience in his own house there is no advantage offered by a nursing home that a patient in well-to-do circumstances cannot get if he is in the hands of a careful medical attendant who has provided good nursing. There are, however, several disadvantages from which he will be free. First of all he will be among his own people, and this is not simply a sentimental consideration, but often one of therapeutic influence. We are, of course, excluding all cases in which removal from familiar surroundings and too sympathetic friends is an essential part of treatment. Again, choice of food will be freer, subject to professional advice, and the manner in which it is served will be more to the patient's taste than is possible at any rate in most nursing institutions. Quiet, too, is far more easily obtained in a private house than in a nursing home, where there is an inevitable amount of constant movement due to the passing to and fro of nurses, the arrival and departure of surgeons and physicians and anæsthetists, and the visits of friends. With regard to the visitors there is in some homes an amount of tyranny exercised that is unknown to the medical man in charge of the case but is very annoying to his patient. The matron may decide that a patient is to see nobody on a certain day, and the very visitor may be refused admittance whose presence would have favourably influenced the progress of the case.

We have mentioned the surgeon's point of view, in which must be included the great advantage to him of being able to see several patients in one visit to a home, that home being probably quite close to his residence. We have considered the point of view of the patient. Now there is a third aspect of the case requiring attention—that, namely, of the general practitioner. When the patient is placed in a surgical home it often means that visits entailing no exercise of particular skill are paid by the operating surgeon, often a comparative stranger, rather than by the general practitioner to whom the patient is accustomed and by whom he would be welcomed. The surgeon no doubt has said, "Come and see your patient whenever you like," but perhaps the home is not within the practitioner's usual round, and perhaps he knows that the patient will not relish paying for two professional visits when only one is necessary. When after-treatment requires particular knowledge and skill the case is, of course, different; but in the vast majority of instances the general practitioner, fortified by the definite instructions which he will be careful to receive from the operator, is perfectly capable of taking charge of the case. He will naturally arrange for additional visits from the surgeon as may be necessary. The surgeon should not overlook the point of view of his colleague the general practitioner nor forget that the patient, whose welfare and comfort are of course the main objects of both, may desire to see and consult his regular adviser. Such are the pros and cons of the surgical home question. From them, in our opinion, it becomes apparent that the main objects desired—namely, the patient's safety and comfort and the surgeon's and practitioner's convenience, will be as well, and often better, met if the sufferer is nursed in his own house than if he is bundled willy-nilly into the strange surroundings of a nursing home.

◆

On Coming Back.

THE proper conduct of a holiday is a subject upon which many writers have expatiated from different aspects. We have pointed out in these columns the futility of making a holiday only a change of work, and have urged upon persons no longer in their first youth to refrain from rushing to Switzerland, immediately to climb mountains regardless of the facts that their arteries are no longer so elastic as formerly and that their heart muscle is somewhat more easily tired than of yore. But if the change from work to play has its dangers so also has the return from holiday-making to the daily grind of professional or office work. The change in methods of life is not properly appreciated, and in the desire to extend the holiday to its utmost limit the return journey is apt to be made at the greatest possible speed, so much so that we know of certain instances where the repatriated travellers have been compelled to rest for a week to recover from fatigue. But allowing that the holiday has been a real holiday, a time of rational enjoyment and of healthful exercise duly adjusted to the physical condition of the holiday-maker, the return to work is often accompanied by attacks of ill-health. It is not at all uncommon in our experience for those who return to London (or to any large city) from a country holiday to complain of suffering from a form of sore-throat. The explanation of this is probably to be found in the presence of dust in the air; and this dust, in London at any rate, is mainly composed of horse-dung, particles of wood, and the various débris to which four or five millions of human beings constantly moving about naturally give rise. All this foreign matter sets up an irritation in the air-passages and pharynx. After a residence of some weeks in the midst of a more or less polluted atmosphere the tissues get acclimatised to the irritation and the cough and sore-throat subside, but they are one source of malaise which has to be looked for after a holiday. We do not suggest that, because continued residence in a large town begets a certain amount of tolerance, therefore it is of no avail to go away; for although a holiday may make the tissues more responsive to external irritation yet the same holiday increases the resisting powers of the body, so that it repels with greater ease the attacks of other poisons. Therefore too much importance must not be laid upon the fact that many persons who felt in robust health while away on their holidays, upon returning have the sensation of being worse in health than they were before they went away. Their natural disappointment at these sensations can as a rule be justly removed by a few optimistic words. Yet again, too little is made of the change from active exercise to sedentary life. From passing most of his time in the open air engaged in some form of exercise a man turns suddenly to working in an office or study—in the case of members of our own profession to going from one sick-bed to another. There is no section of the community so notoriously careless of its own health as is the medical profession, and while its members would impress upon the returned worker to avoid errors in diet we doubt whether it is their habit to be careful themselves in this respect. It cannot be too much insisted on that, although on a holiday a large breakfast, a large luncheon, and a large dinner may be partaken of with impunity, under the altered conditions of the working life no such heavy feeding can be right. To a man employed in fishing or shooting most of the day, or to one who spends his time in walking or bicycling, a dose of alcohol may give a feeling of contentment as well as wholesome slumber at night, which it will completely fail to do when the daily round of work is taken up again. Properly enjoyed and used a holiday is of illimitable use and if care be taken the return to work will be felt to be all the more easy for the rest enjoyed during the vacation. But it is impossible to combine, as so many think they can do, the brain expenditure of work-time with the physical digestiveness of play-time.

Annotations.

"Ne quid nimis."

MR. BRODRICK'S COMMITTEE ON THE ROYAL ARMY MEDICAL CORPS.

ALTHOUGH the report of Mr. Brodrick's Commission on the reconstitution of the Royal Army Medical Corps is not yet published there can be no indiscretion, we think, in saying that the document, when it appears, will give considerable pleasure to those interested in the branch of the service concerned. The report will recommend that the Royal Army Medical Corps should be in the hands of an advisory committee, not an unwieldy one, to be made up of the Director-General, certain officers of the Royal Army Medical Corps, certain civilian medical men, and certain War Office officials. The dignity of the position of the Director-General will, we hope, be preserved, while his responsibility will be lightened. Three changes will be suggested as making for the better scientific education of the officers of the corps. A candidate for the Royal Army Medical Corps, if on the verge of holding an appointment as house surgeon or physician, is to be allowed after passing his examination for the Royal Army Medical Corps to hold his appointment and to count the term of office as part of his military service. By this wise recommendation the Commissioners attempt to secure for the service what may be termed the flower of the medical students. Study leave, which has always been somewhat of a farce, is to be done away with, but in its place surgeons are to be gazetted to large provincial or metropolitan medical centres where they can attend hospital practice and perform their duties as military surgeons as well. Lastly, but not lastly in importance, the pay will be increased. The Commissioners have not taken into question the Indian Medical Service at all. This service is in no way touched by these recommendations, and no amalgamation of the Royal Army Medical Corps with the Indian Medical Service appears to have been contemplated.

THE NEW CRANIOMETRY.

IN his Presidential Address delivered to the Anthropological Section of the British Association Professor D. J. Cunningham, while reviewing the features which distinguish the brain of man from that of the higher apes, entered a powerful but, many will think, a premature plea for the careful consideration and, where possible, the revision, of the present system of craniometry. Broadly speaking, the cranium under normal circumstances was considered to exert but little influence in determining the head form, so that, he said, "in speaking of brachycephalic or short heads and dolichocephalic or long heads we are merely using terms to indicate conditions which result from individual or racial peculiarities of cerebral growth." Probably few anthropologists would deny this, yet if followed to its logical conclusion the cephalic or length-breadth index, for instance, should be derived from measurements taken from the interior of the skull. This is Professor Cunningham's view, which he supported by the argument that "the measurement of the long diameter of the cranium does not give the true length of the cranial cavity. It includes, in addition, the diameter of an air-chamber of very variable dimensions which is placed in front." A case in point was given. "Measured in the usual way the Neanderthal skull is placed in the dolichocephalic class, whereas Schwalbe had shown that if the brain-case alone be considered it is found to be on the verge of brachycephaly," while Huxley was quoted to the effect that no "safe basis for that ethnological craniology which aspires to give the anatomical characters of the crania of the different races of mankind" will be found "until it shall become an opprobrium to an ethnological collection to possess a single skull which is not bisected longitudinally." While regretting that our present knowledge of cerebral growth and the value to be attached to its various manifestations was still so far from complete, Professor Cunningham held that since "the areas of cerebral cortex to which man owes his intellectual superiority are now roughly mapped out, the time has come when the effect produced upon the cranial form by the marked extension of these areas in the human brain should be noted, and the skulls of different races contrasted from this point of view." He dwelt on the development of the occipital lobe and its predominance in apes, especially the lower forms, while he discussed the great size of the parietal lobe—"a leading human character"—in relation to the morphology of the insular district. The opercula appear early, the fronto-parietal and temporal opercula being together responsible for closing over more than three-fourths of the insula. At first the lower or temporal operculum grows more rapidly upwards than the fronto-parietal grows downwards, hence the former covers in a greater part of the insula, and the Sylvian fissure formed by the approximation of the margins of the opercula runs very obliquely upwards and backwards as in apes. At a later stage, when the frontal and parietal lobes assume their more distinctly human characteristics, correlated by Professor Cunningham with the increased complexity and differentiation of the functions and movements which they govern, the fronto-parietal operculum enters into a growth antagonism with the temporal operculum which results in the latter being pressed down and the Sylvian fissure assuming its almost horizontal human position. It is especially interesting that on the left side the Sylvian fissure is more depressed than that of the right hemisphere, the surface area of the left parietal lobe being greater than that of the right. Three ready-made explanations, as frankly teleological as any ever taught in a dissecting-room, were at Professor Cunningham's service to explain this condition, and it was with a feeling of relief that we read "not one of these theories when closely looked into is found to possess the smallest degree of value." Even the obvious explanation that the increase in size of the left parietal lobe is associated with right-handedness is regarded as doubtful since it occurs in apes, among whom Professor Cunningham has been unable to satisfy himself that there is any decided preference for the use of one arm more than another. Finally, the manner in which speech assumed shape in man's early ancestors was briefly discussed, Professor Cunningham laying stress on the value of the imitative theory and following Darwin in being "inclined to believe that articulate speech came at an early period in the history of the stem-form of man."

INEBRIATE REFORMATORY HOMES.

ONE consequence of the Inebriates Act of 1898 has been the establishment in various parts of the country of reformatory homes for persons whom repeated convictions for drunkenness have rendered eligible for admission. We learn from the latest report of the Reformatory Committee that 18 county divisions and 78 county and municipal boroughs—a relatively small proportion to the whole—have availed themselves of the facilities granted under the Act for this purpose. The reformatories established comprise the following: Ashford, Brentry and Horfield near Bristol, Duxhurst Farm Colony, Girgenti (Ayrshire), Farmfield (Surrey), Ennis, and Perth. These collectively afford accommodation at the present date for 357 females and 164 males. So far the details to hand of work accomplished in these homes are very scanty. Only those obtained from the institutions at Ashford and Brentry are approximately complete. The record of results at the former home shows that of 28 persons discharged on licence during the year ending on March 31st 14 are doing well and 14 have had their licences revoked. In the case of Brentry a brief note asserts that "far too many [of persons out on licence] are doing badly." So far, then, it cannot be said that home reformatories have achieved very great success. The work, it is true, is still young and is quite in the experimental stage. It is not to be expected that it will prove entirely successful, nor, on the other hand, can it fail under reasonable conditions to accomplish a certain amount of good. How much benefit may be fairly expected of it is quite an open question. The answer to it with which experience has provided us does not so far justify an optimistic view. Happily, there is no necessary finality in speculations of this kind and hope finds a place in every counsel of reform. Another question, and a very practical one, is whether the means employed are those most likely to attain the object in view. It will not do to look upon the drunkard as a pure and simple invalid or a lunatic. If he is such his place is not in a reformatory. He is essentially one who has acquired a bad habit and has indulged it until, as always happens with our pampered fancies, it has become his master. Reform in his case, therefore, implies a process of disentanglement, the removal of temptation, the stimulation of any energy remaining in the will and its employment for wholesome ends. Not nursing, not rustic beauty, ease, and recreation are required to carry out the common rule of this kind of reformation. As judged of by photographic views the arrangements at Brentry appear too luxuriously considerate to give promise of the best results. We would rather prescribe a condition of plain, quite plain, comfort, with abstinence from alcohol, and, above all, with regular and pretty continuous occupation in any suitable form. Homes arranged on this model have a further advantage in the fact that they might be made in great measure, if not entirely, self-supporting. Such, we believe, they ought to be. The thrifty and well-doing members of the community already bear the heavy burden of expenditure for national purposes, besides the maintenance of the aged, the sick, the destitute, and the insane. They may reasonably ask that the cost incurred by vicious habits should rest as far as possible on those immediately responsible. We are of opinion that they will agree with us in upholding the general principle that inebriate reform and reformatories should be conducted as far as possible on the lines of self-support.

DRY WASHING.

IT is a familiar boast of English people that we are above all others a washing nation. Soap-and-water is a standing dish in Great Britain, but so little were we disposed to credit the habitual cleanliness of foreigners that a piece of soap in the valise was till recently the habitual companion of an Englishman on his travels. Nowadays such an item is scarcely a necessary part of the traveller's impedimenta, though there are still fair-sized hotels on the continent where soap may be searched for in vain in the bedrooms, while the smallest inn in this country would blush to the roof at such a deficiency. All kinds of theories have been raised to account for this national tendency to ablution, and most diverse qualities have been attributed to its possession. The familiarity of islanders with water, and the use of it occasioned by the national custom that led the ancient Britons to paint their bodies, are solemnly urged as the foundation of the English proneness to washing; and the fresh complexions and smooth skins of young Englishmen are held to replace the more dusky and hirsute countenances of the Latin races because of their closer and more frequent acquaintance with the articles of the washstand. With fanciful theories we have naturally no concern, and we believe that clear ruddy cheeks are a national inheritance for the same, if equally indiscernible, reasons as a tendency to roam or a dull ear for music. If, however, we do not attempt to explain the presence of a widespread habit and leave it to idle imaginations to determine why Englishmen wash, it is nevertheless our concern that such habits should be for the general welfare and should not be carried to injurious excess. It is quite obvious that even in England there are people who wash too little. It is not so generally recognised that some people wash too much. The skin is not well adapted to frequent applications of water accompanied by even the least irritating of soaps.

A tendency arises to maceration of the superficial part of the epidermis, which is too frequently removed and occasions probably too rapid a proliferation of the cells of the Malpighian layer. There is no doubt that many cases of roughness of the skin of the face come from the frequent applications of water. It is a good thing to rub the face with a soft, clean, dry towel two or three times a day. If, in addition, water is used in the morning and at night the skin will be kept in a sounder, smoother, and healthier state than if, as is often the case, soap and water are used three or four times a day. Men are not often offenders in this respect, most men sparing little time for the refinements of the toilette. Women and children, whose skins are the most easily affected by superfluous ablution, are the very persons in whom such excess is too common. They should be taught that there are dry methods of cleanliness as well as wet ones.

IDIO-MUSCULAR CONTRACTION AS A DIAGNOSTIC SIGN IN MENTAL DISEASES.

Dr. S. Soukhanoff and Dr. P. Sannouchkine of Moscow contribute the results of a lengthy research on this subject to the *Revue Neurologique* of August 15th They refer to the statement of certain authors who claim idio-muscular contractility as an aid to the more exact diagnosis of disease—e.g., Bernstein[1] who has investigated this symptom in great detail. The investigation of Dr. Soukhanoff and Dr. Sannouchkine was carried out on 355 patients from the psychiatric clinic of the University of Moscow and the special muscle selected for the test was the biceps of the upper arm which was percussed with a small hammer. The following were the results obtained. 1. In a general way idio-muscular contraction was absent in 15·2 per cent. of the cases, it was slightly marked in 11 per cent, and well marked in 73 8 per cent. Thus, in the majority of cases of mental disease it showed itself in a marked manner 2. The forms of mental disease classified below gave the following results :—

Form of mental disease.	Idio-muscular contraction		
	Absent.	Feeble.	Marked.
Melancholia	2 cases.	2 cases	17 cases.
Amentia of Meynert	3 ,,	—	17 ,,
Idiocy and imbecility	1 case.	4 cases.	15 ,,
Paranoia	1 ,,	4 ,,	15 ,,
Dementia præcox	3 cases.	1 case.	13 ,,
General paralysis	8 ,,	2 cases	52 ,,
Acute alcoholic insanity, not including delirium tremens	1 case.	1 case.	9 ,,
Prolonged alcoholic delirium	—	—	10 ,,
Epilepsy	—	—	11 ,,

Its diagnostic value thus becomes considerable, and this is enhanced by the fact that the authors took care to exclude all phthisical cases from their research to obviate the well-known tendency to idio-muscular contraction which is developed in phthisical patients. 3. In the other forms of mental disease the frequency of occurrence of idio-muscular contraction was as follows: in secondary dementia it was 62 5 per cent., in chronic alcoholism and dipsomania it was 63·6 per cent., in the degenerative psychoses (insanity of obsessions, hypochondria, and the aboulic neurasthenias) it was 64 1 per cent., and in periodic insanity it was 68·3 per cent. 4. The authors point out that in pubescent and adolescent subjects there is normally a condition of irritability of muscle which renders the manifestation of idio-muscular contraction easy. The value of this symptom as a diagnostic measure thus increases when adolescence is past and the patients are persons of adult, middle, or old age 5. The singular feature of its occurrence in every case of epilepsy with insanity, and of prolonged alcoholic delirium, is emphasised by the authors, who also draw from their research the conclusion that when the nutrition of the patient is low idio-muscular contractility tends to appear. It is important in every case to examine the patient for phthisis, as the absence of the latter makes the value of idio-muscular contraction as a diagnostic sign greater in mental diseases.

THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope, received at the Colonial Office on Sept. 18th, states that for the week ending Sept. 14th the cases of plague in the Cape Peninsula numbered 0. At Port Elizabeth the cases were as follows: Europeans, 2; natives, 8. In all other places the cases numbered 0. The deaths were as follows: Cape Peninsula, 0; Port Elizabeth, 1, a native. In all other places the deaths numbered 0. The area of infection remains unchanged and the cases of plague among persons under naval and military control numbered 0 As regards the Mauritius a telegram from the Governor, received at the Colonial Office on Sept. 20th, states that for the week ending Sept. 19th there were 24 cases of plague and 17 deaths. At Hong-Kong a telegram from the Governor, received at the Colonial Office on Sept. 23rd, states that for the week ending Sept. 21st there were 2 cases of plague and 2 deaths As regards Egypt during the week ending Sept. 15th 11 cases of plague and 6 deaths from the disease have been reported throughout all Egypt Of these 1 admission, 1 death in hospital, and 1 death out of hospital were reported from Port Said; from Alexandria 4 admissions, 2 deaths in hospital, and 2 deaths out of hospital; from Mit Ghamr 2 admissions; and from Benha 2 admissions.

"PUBLIC BODIES AND TUBERCULOUS FOODS."

IN THE LANCET of Sept. 14th (p. 745) we commented upon the activity shown by various public bodies with regard to the possible dangers accruing from tuberculous meat and milk We instanced the memorandum issued by the medical officer of health of Finsbury, and we have now received a similar memorandum from the Public Health Department of the Borough of Stockport. The circular is as follows :—

COUNTY BOROUGH OF STOCKPORT.

PUBLIC HEALTH DEPARTMENT.

Great Egerton street, Stockport, Sept. 18th, 1901.

SIR,—I am directed by the Sanitary Committee to draw your attention to the fact that it has recently been denied by Professor Koch that tuberculosis can be transmitted from animals to man. The views expressed by Professor Koch have not by any means received the [illegible] ust been appointed to inquire [illegible] Professor Koch. Pending the [illegible] Commission the Local Govern[illegible] cal authorities that they should [illegible] as heretofore for dealing with [illegible] berculous meat. [illegible] esire you to understand that [illegible] degree the taking of all proper [illegible] the sale of tuberculous meat and milk.

In the case of meat they will, through their officers, carry out the [illegible] from tuberculous animals on the lines laid down by the [illegible] the case of milk from tuberculous [illegible] as heretofore in accordance with the [illegible] als, and Milkshops Orders, 1885 and 1899, and the Stockport Corporation Act, 1899

Notice of the provisions of these Acts has already been sent to you and information relating to them can always be obtained on application at this office.

The attention of butchers and meat-dealers is called to the fact that in cases where the existence or extent of any disease in an animal intended for human food is doubtful, or where there is any uncertainty as to the fitness or otherwise of any meat for human food, they should at once send word to the Sanitary Office and obtain the opinion of the medical officer of health or an inspector of the Sanitary Department.

When this is done nothing whatever should be removed from the carcase or meat in question until it has been seen by the Sanitary Department officials, since if anything be dressed or trimmed away or any parts be missing the officials of the department are instructed to regard such missing parts as having been in the worst condition possible and to form their opinion as to the remainder of the carcase accordingly. The Sanitary Committee will not take any action against butchers or meat-dealers who carry out the suggestion contained in this paragraph in good faith, but they reserve to themselves the right of taking legal proceedings (even though information be sent to them as suggested) should they have the slightest doubt about the perfect good faith of the responsible person. (Signed)

---

[1] Archives Russes de Pathologie, 1899, and Thèse de Moscow, 1900

MEREDITH YOUNG, M.D., D.P.H., Medical Officer of Health.

The last paragraph is, to our minds, particularly admirable. Objection to inspection, whether in the case of laundries or of school boards, is almost a proof in itself that there is something wrong, and we think that the Sanitary Committee of the Stockport Public Health Department has acted most wisely.

EYE DISEASE IN THE RUSSIAN ARMY.

THE *Voenno-Medicinski Journal* for April last contains an article by Dr. Reich on the prevalence of ophthalmic affections in the Russian army. According to a review of this contribution in the *Archives de Médecine et de Pharmacie Militaires* for the current month it would seem that although in many respects the sanitary condition of the Russian army has advanced of late years there is still considerable room for improvement with regard to eye diseases, especially among the troops quartered in the Eastern and South-eastern provinces. At first sight the proportion of 16·8 per 1000, which represents the official rate for eye affections in the Russian army, does not strike an observer as excessive, but on closer examination it will be found that this ratio refers merely to cases admitted into hospitals and takes no account of those which are treated in the infirmaries. The vital statistics of the latter class of establishment are, unfortunately, not available, but the writer of the article is satisfied that from 100 to 360 Russian soldiers out of each 1000 are treated in them for ophthalmic affections. He is also of opinion that in the year 1898 no fewer than 70,000 men were suffering from pathological changes consecutive to trachomatous conjunctivitis, this number representing 70 per 1000 of the total strength. Incidentally he mentions the fact that out of 1047 men who were invalided from four different military districts on account of affections of the organs of vision and their annexes 500 were victims to trachoma and its sequelæ.

A CLINICAL CLASSIFICATION OF INSANITY.

PROFESSOR F. X. DERCUM of Philadelphia contributes to the September number of the *Journal of Nervous and Mental Disease* a paper in which a practical attempt is made to give a clinical classification of mental disease which may be helpful to the student and general practitioner. He regards classification based upon psychology, etiology, or symptoms as unsatisfactory, and thinks that the insanities may be disentangled from one another and the various clinical forms arranged in five or six groups, the members of any one group being closely allied to one another. Thus, starting with delirium, which is manifested in the child by incoherent cries, mental confusion, and fleeting hallucinations, he divides it into febrile and non-febrile forms. The febrile form of delirium is associated with acute infectious fevers—e.g., pneumonia and scarlet fever; the non-febrile form with alcoholism, plumbism, trauma, and shock, or with the post-febrile (convalescent) stage of fevers. The special form of insanity known as "acute delirium," or typhomania, should be included also in this group. When a condition of debility or of mental exhaustion (asthenia) with stupidity is present, agencies which otherwise would give rise to delirium produce stupor. In this condition there is mental confusion attended with great obscuring of consciousness, so that conduct and expression are in abeyance. There may be all grades of stupor down to complete suspension of mental activity (anergic stupor). The three forms of mental disorder—delirium, mental confusion, and stupor—are members of one clinical family group. In mania, melancholia, and circular insanity we have another group. The identity of the etiology of mania and melancholia, the great rôle of heredity in their production (80 per cent. according to Kraepelin), and the fact that both affections occur in persons of emotional and excitable nature and in early adult life, emphasise the affinity of these disorders. Mania and melancholia both tend to recover, to recur, and to blend and alternate with one another in the circular form of insanity. Indeed, so closely are the two disorders related that Kraepelin has proposed to include both under the common designation "manisch-depressive Irresein." This group differs from the delirium-stupor group. Paranoia, or chronic delusional insanity of gradual evolution, starting from a hypochondriacal basis and passing on through hallucinations to delusions of persecution, forms a third group. Here the evolution of symptoms is slow and occupies many years, and when the delusions have fully developed a transformation of the *ego* takes place and the sense of personal identity is altered. Paranoia comes close to the mania-melancholia group in its symptoms and sequelæ. The neurasthenic insanities form a fourth group, in which are included simple cerebral neurasthenia, morbid fears and paralyses of the will (e.g., agoraphobia and dipsomania), *folie du doute*, and the other forms of insanity attended with mental obsessions. Many of these forms of mental disorder occur in "degenerates," whose mental development in childhood and youth have proceeded on abnormal lines. The fifth group includes dementia. To this belongs dementia præcox, a condition to which attention has already been drawn in these columns,[1] katatonic insanity, and general paralysis of the insane. Lastly, a diathetic group of mental disorders exists, associated with an abnormal metabolism of the body, such as the insanity of diabetes, gout, and rheumatism, and an intoxication group of mental disorders due to alcohol, lead, opium, and cocaine.

DISSATISFACTION IN THE MEDICAL DEPARTMENT OF THE UNITED STATES ARMY.

A FREQUENT correspondent writes to us from New York as follows:—"The provisions of the United States Army Reorganisation Bill affecting the Medical Department which was passed by Congress last session have given rise to much discontent among army surgeons in the United States. The grading of medical officers has been rendered lower than that of any other branch of the military services. The *New York Medical Record* of August 10th has a fair but pungent criticism of the altered conditions which has called forth a somewhat apologetic reply from the *Army and Navy Journal.* The *Army and Navy Journal*, however, undoubtedly hits the right nail on the head when it declares that the medical corps has suffered because medical men ignore their own interests, and because army surgeons have refrained from joint action. Until medical men as a body become convinced that they must exert themselves in the field of politics their interests will be regarded with more or less indifference. Organisation for medical men is essential both in army and civil life if they are to hope for fair dealing at the hands of Congress." The situation in the United States and in Great Britain as regards the army medical departments of both countries is in many respects identical, and in both countries the power of union is recognised even if its principles are somewhat ignored. Undoubtedly the pressure which our American correspondent thinks should be brought to bear on Congress might in this country well be employed in Parliament upon many questions of medical interest; but it is difficult with us to be a politician without being a party politician. And medical men feeling this do not enter an arena where they might often serve their generation well, while upholding the prestige of their order.

[1] THE LANCET, Feb. 3rd, 1900, p. 397.

SIR JAMES PAGET'S MEMOIRS.

A GLANCE at the "Memoirs and Letters of Sir James Paget," published this week by Messrs. Longmans, Green, and Co., has enabled us to see how fascinating a book Mr. Stephen Paget has compiled in his father's memory. Though dealing with a long life and one of more importance than some to which greater volumes are dedicated, the book is not a massive one. It contains some charming portraits and other illustrations, and is divided into two portions, the first containing the whole of the memoirs left by Sir James Paget and the second giving an account of his later life. The volume is one that many medical men will be eager to possess, the reasons for which opinion we shall give after further perusal.

FEES FOR THE CERTIFICATION OF LUNATICS.

AT a recent meeting of the Southwark Guardians, held at the offices, John-street West, Blackfriars-road, the Finance and General Purposes Committee reported that they had had under their consideration the question of the amount of the fees paid to their medical officers for the certification of lunatics. They recommended the board to approach the various justices of the peace who were in the habit of dealing with the lunatics of the union with a request that they should direct a fee of 10*s.* 6*d.* instead of 21*s.* to be paid to the medical officers of the union in future, as that sum seemed, in the opinion of the committee, to be a reasonable amount for the services rendered, having regard to the fact that the medical officers were paid officials of the union. Mr. T. Cooksey, the chairman, congratulated the committee upon endeavouring to cut down expenses in view of the great increase in the board's expenditure—and the recommendation was adopted. Guardians have looked upon the fees paid to their medical officers for the certification of lunatics with much disfavour. They have an objection to the system under which the payments are made, for they have no legal control over the amounts paid. By Section 285 of the Lunacy Act, 1890, the justice orders the payment by the guardians of what he considers to be a "reasonable remuneration" for the examination and certification of a lunatic. Many guardians have expressed their opinion that a guinea is a large fee for merely, as they think, writing a statement that A. B. is a lunatic. They have no idea of the mental and physical labour involved in the daily record of the patient's symptoms; in the accurate descriptions in the case-book of every little bruise, scar, and abrasion which the patient had on his body when admitted; and in the careful examination of the whole person and notification of every abnormal appearance which are required on the day the patient is removed to asylum. The guardians have little regard for the mental strain which is undergone by the medical officer when he is dealing with the numerous "border-line" cases sent into the wards. In these he writes his certificate with a sword of Damocles over his head. The least error or mis-statement may make his certificate quite invalid, may bring him into difficulty with the Commissioners in Lunacy, may make him guilty of a misdemeanour, or may render him liable to heavy pecuniary damages. If, on the other hand, he refuses to certify on the ground of insufficient evidence, and the patient is discharged, there is the not by any means uncommon result of a suicide or a homicide, with more trouble for the medical officer. These are some of the circumstances under which we think the fee of one guinea to be thoroughly well earned. There is, however, another aspect of the question before us. The guardians, knowing from past experience the average number of lunacy fees to be paid in the year, have in many instances fixed the salary of the medical officers at a mere nominal sum for the work to be done. They have stated that they considered the fees would bring the remuneration to an adequate amount. It would not be difficult to name a large metropolitan workhouse containing about 1600 people where the medical officer receives a salary of only £50 a year. The guardians are quite aware that the lunacy fees are the real salary and that without them no medical officer would hold the post for the sum they have fixed. Bearing the fact in mind that a similar method of utilising the lunacy fees obtains at many large workhouses, let us ask the question whether the action of the guardians in requesting the justices to award diminished fees is not a departure from fair and straightforward dealing? It is not likely, however, that the justices will be influenced. They will not readily surrender any of the power they hold under the provisions of the Lunacy Act.

THE DIAGNOSIS OF ADDISON'S DISEASE WHEN PIGMENTATION IS ABSENT.

IN exceptional cases of Addison's disease the characteristic pigmentation is absent. In ordinary cases the pigmentation can be locally intensified by irritation, such as the application of a blister. This fact might have suggested the possibility of producing pigmentation by irritation in cases in which it is entirely absent, but such an experiment does not appear to have occurred to anyone. At the meeting of the Société Médicale des Hôpitaux of Paris on July 19th M. L. Jacquet and M. Trémolières related two cases in which pigmentation was thus produced accidentally. In the first, a case of spinal caries, the application of poultices produced pigmentation of the abdomen and the necropsy revealed tuberculosis of the suprarenal capsules. In the second case the patient was a man, aged 31 years, who was admitted to the Saint Louis Hospital on Feb. 28th, 1901. He was very feeble and "wasted to a skeleton." He suffered from acute and incessant abdominal pains, especially in the right iliac fossa. They were increased by movements and by light pressure, relieved by deep pressure, and became recrudescent about two hours after meals. After paroxysms of pain vomiting supervened Slight pigmentation had recently appeared in the fronto-temporal regions and there were one pigmented spot on the upper lip and another on the lower lip. At the apex of the left lung was a cavity and at the base friction sounds were heard. Fulness was felt in the epigastrium. To relieve the pains linseed-meal poultices with a little mustard and compresses of camphorated alcohol were alternately applied to the abdomen About a fortnight afterwards marked brown pigmentation of the abdomen was noticed. The pigmentation extended beyond the limits of application of the poultices The hairs were not hyper-pigmented. On July 18th the pigmentation was still present and of the same intensity, though no applications had been made to the abdomen since April. The poultices and compresses were applied to the anterior surface of the right thigh A rosy and transitory discolouration was first produced. In some days it became red and permanent. In less than three weeks pigmentation similar to that of the abdomen was produced. Linseed-meal poultices (without mustard) were applied daily for two hours to the left shoulder, beginning on June 12th After the removal of the poultice a rosy tint remained which progressively became more and more intense and persisted longer and longer. On July 2nd it was red and permanent and pigmentation was commencing. On July 6th the latter was well marked. In a similar manner pigmentation was produced on the calves. The importance is obvious of this method of *extériorisation de la mélanodermie latente*, as the authors term the phenomenon. The diagnosis of Addison's disease in the absence of pigmentation can thus be made possible.

THE MEDICO-LEGAL ASPECT OF WOUNDS.

IN many cases of suspected murder we have to depend chiefly on circumstantial evidence, and the most important elements in determining whether certain wounds could have been self-inflicted are their position and their extent. In THE LANCET of Sept. 14th, p. 744, we published a case of suicide in which the wounds were inflicted on the back of the neck, and in the present issue is a letter from Dr. J. Little of Maryport in which he points out that we published two similar cases in 1889. In nearly all cases of self-inflicted wounds the injuries are on the anterior aspect of the body, and the reason is obvious, for the front of the body is necessarily much more accessible; if, therefore, in any case we find that the wounds are all or chiefly situated posteriorly the first idea is that they have been caused, not by the wounded man himself, but by someone else. Yet these three cases which we have mentioned demonstrate conclusively that the mere position of the wound is no true criterion of its source. The extent of the wounds inflicted has also frequently served to distinguish suicidal from homicidal injuries, but this diagnostic point also is very fallacious. The cases already referred to, and especially a case of auto-extirpation of the larynx upon which we commented in THE LANCET of Sept. 21st, p. 801, demonstrate clearly that very severe injuries may be self-inflicted. The medical "expert witness" must exercise great caution in saying that certain injuries could not have been self-inflicted. The life of an innocent prisoner may depend on his decision

REPORT ON LUNATIC ASYLUMS IN NEW ZEALAND.

IN the report recently issued by the Inspector-General of Asylums of New Zealand for the year 1900 it is stated that the total number of registered insane persons on Dec. 31st, 1900, was 2672, being an increase of 115 over the previous year. The public asylums number seven in all, the accommodation varying from 120 beds (Hokitika) to 625 beds (Dunedin), while there is but one private asylum which accommodates 45 patients. The proportion of the male insane to the male population of the colony is 1 to 270, and for the female insane the proportion is 1 to 351. The total insane are in the proportion of 1 to 303 of the general population, a ratio almost exactly identical with that of England and Wales. A number of interesting observations are scattered throughout the report. Dr. R. M. Beattie, the medical superintendent of Auckland Asylum (487 beds), states that about 16 per cent. of the deaths were due to phthisis, and that as long as Maori patients are admitted it will be impossible to reduce the mortality from this source. A considerable proportion of the Maoris are phthisical upon admission, while others acquire the disease with remarkable facility. At the Wellington Asylum (280 beds) Dr. W. Baxter Gow, the medical superintendent, urges the erection of a separate ward or block for the reception of acute and recent cases of insanity. Owing to want of such accommodation there is not only some degree of overcrowding, but the chances of recovery of recent cases are diminished from contact with chronic and refractory cases of insanity. At Seacliffe Asylum a suicidal patient escaped from the attendants into the bush and hanged himself before those who were pursuing him could find his exact whereabouts. Of the causes of deaths two are attributed to alcoholism, 10 to cerebral hæmorrhage, eight to Bright's disease, 10 to epilepsy, 12 to senile decay, 22 to general paralysis, 24 to phthisis and other forms of tuberculosis, 32 to cardiac disease, 40 to pneumonia, and the rest to other causes. The total number of deaths during the year amounted to 145, or 5·61 of the average number resident, a ratio which is about half that of England and Wales. The number of cases discharged as recovered during the year was 199, or 7·5 per cent., as calculated on the same basis, being about two-thirds of the recovery-rate in England and Wales. Seacliffe Asylum at Otago is the largest in the Colony; 16 years ago it was described by the then Inspector-General in his official report as "out-of-date and defective in construction." During the last 12 years extensive and thorough alterations in the building, including lighting, ventilation, and drainage, have been steadily carried out to remedy these defects, and it has now "been brought to such a condition that Otago may well be proud of it." The report is of interest as showing what enlightened medical opinion and steady perseverance can accomplish in the way of treatment of the insane in a colony as far removed from the mother country as New Zealand. "The medical superintendents [of the asylums] are," concludes the Inspector-General in his report, "without exception highly qualified and deserving of the highest confidence and esteem. No department could have better officers." The separate reports of the various asylums incorporated in the text fully bear out the view that steady progress is being achieved in the treatment of the insane in New Zealand.

SMALL-POX IN LONDON.

THERE is as yet no abatement in the outbreak of small-pox in London. We refer in a leading article to the vigorous circulars addressed to boards of guardians, sanitary authorities, and borough councils of the metropolis by the Local Government Board. During Wednesday, Sept. 25th, five cases of small-pox were notified, it appears from the returns issued by the Metropolitan Asylums Board. The deaths from small-pox, which had been seven, seven, and nine in the preceding three weeks, fell last week to three, all of which belonged to the borough of St. Pancras. The total number of cases in the isolation hospitals is now 165. At a meeting of the St. Pancras Borough Council held on Sept. 25th the report of the Public Health Committee was presented, with which was incorporated the report of the medical officer of health upon cases of infectious disease certified during the weeks ended August 31st, Sept. 7th, and Sept. 14th. There was also a further report upon the present outbreak of small-pox in the borough which was illustrated by spot maps. Dr. Sykes pointed out the difficulties of diagnosis, and with regard to the all-important question of dealing with contacts recommended either immediate vaccination or revaccination, or else a quarantine period of 14 days. It had been found effectual to quarantine all persons in an infected house for at least 14 days and only to release them upon being vaccinated. There was no legal power to do this, but in the face of the epidemic it was a serious matter for consideration. The committee had approved of the closing of certain schools, both board and national. The council by 42 votes to 13 carried the following recommendations of the committee:—

(*a*) That it be suggested to the guardians to instruct their officers dealing with vaccination, or their assistants, to pay particular attention to suspicious rashes and illnesses, and where no medical practitioner is in attendance to report such to a medical practitioner of experience in small-pox with a request that he shall forthwith visit and certify, if necessary.

(*b*) That in each ward a medical man be appointed as medical referee to be called in by the medical attendant in doubtful cases of small pox or suspicious eruption or symptoms, and to be paid a small fee per case.

(c) That as a matter of urgency on account of the prevalence of small-pox an Order be made under Section 55 of the Public Health (London) Act, 1891, with respect to the notification of infectious diseases to apply to the borough of Saint Pancras as to chicken-pox, the Order to continue in force for a period of six months, and that a [illegible] directed.

(d) That in future no candidate for an appointment or applicant [illegible]

The St. Pancras councillors as a body are evidently alive to the exigencies of the situation.

OPENING OF THE METROPOLITAN MEDICAL SCHOOLS.

WITH the exception of Charing Cross Hospital and St. Thomas's Hospital the metropolitan medical schools commence their winter session on Oct. 1st, the two exceptions mentioned starting their winter's work on the following day. Most of the schools begin their work with some sort of social function and all except St. Mary's Hospital, Westminster Hospital, and the London School of Medicine for Women end the day with a dinner, at which past and present students usually meet. St. Mary's Hospital, however, hold a dinner on Oct. 3rd, and Westminster Hospital on Oct. 4th At St. Bartholomew's Hospital the old students' dinner will be held in the great hall of the hospital on Oct. 1st at seven o'clock; Mr. W. J. Walsham will be in the chair. At Charing Cross Hospital Mr. J. W. Taylor, Professor of Gynæcology in the University of Birmingham, will deliver an introductory address at 4 P.M. The old students' dinner will be held at the Hotel Cecil in the evening, when Mr. Charles Gibbs, late surgeon to the Langman Hospital, will occupy the chair. The St. George's Hospital introductory address will be delivered at 4 P.M. by Dr. P. W. Latham, and the annual dinner will be held at the Hôtel Métropole at seven o'clock, when the chair will be taken by Mr. Warrington Haward. Guy's Hospital house dinner of the Students' Club will take place in the college dining-hall on the opening day, but the first meeting of the Physical Society will not be held till Oct. 5th, when Sir Samuel Wilks, Bart., F.R.S., will preside, and a paper will be read by Mr. S W MacIlwaine on Disease and its Causation King's College Hospital old students' dinner will be held at the Hotel Cecil, when Mr. Paul Swain will take the chair London Hospital old students' dinner will be held in the college library of the hospital, Mr. F. J. P. Daly presiding St. Mary's Hospital introductory lecture will be given by Dr G. William Hill, the aural surgeon, but the annual dinner of past and present students will take place on Thursday, Oct. 3rd, at the Whitehall Rooms, Hôtel Métropole, Colonel A. B. R. Myers in the chair. The Middlesex Hospital introductory address will be delivered by Dr. T H Kellock, after which the prizes gained during the previous year will be distributed by Lord Howard de Walden. The annual dinner of past and present students will take place at seven o'clock at the Trocadéro Restaurant, under the presidency of Mr. J. Bland-Sutton. St. Thomas's Hospital starts with a prize distribution by Major-General Sir Ian Hamilton, K.C.B, in the Governors' Hall, at 3 P M During the afternoon the various departments of the hospital and school will be open for the inspection of visitors. The annual dinner will take place at the Whitehall Rooms, Hôtel Métropole, at seven o'clock, Mr. H. H. Clutton in the chair. The University College Hospital introductory lecture will be given at 4 P.M. by Dr. J. Risien Russell, and the past and present students' dinner will take place at 6.30 at the Hotel Cecil, when Sir Richard Douglas Powell, Bart., will preside. Westminster Hospital annual dinner will not take place till Oct. 4th, when Mr. Charles Stonham will preside. At the London (Royal Free Hospital) School of Medicine for Women the introductory address will be given by Dr. F. W. Andrewes on Oct. 1st at 4 P.M.

A HARD CASE.

AN action unsuccessfully brought in the Grimsby County Court recently illustrated the difficult position in which a medical man may be placed where a patient is brought to him whom it would perhaps be inhuman to send away, but with regard to whom there is doubt as to who will be liable for the services rendered. A little girl was brought to the surgery of Mr. T. W. J. Allen, the plaintiff, with a broken arm, and the board school teacher who accompanied her stated that the school board would pay for attendance upon her. The cost of attendance which was accordingly given seems to have been increased by a subsequent injury to the broken arm, but, to put it briefly, the school board repudiated altogether the liability to which it seems clear that its teacher had no authority to pledge it, and which, in the opinion of the county court judge, it would have had no right to incur in any case. Evidence, however, was given by Mr. Allen that he had, in fact, been paid on previous occasions for attendance on accidents in another similar school. In consequence of this refusal the medical man sued the parents, only to be confronted with the undoubted fact that they were poor people who neither had, nor would have, retained his services, but who, had they known of the occurrence, would have had recourse to the hospital Cases such as these are hard upon the medical practitioner, but they show that where attendance is asked for and where there is any possible doubt as to who is to pay for it this should be made clear before the attendance is given. In cases of emergency, such as accidents, the same point should be elucidated on the first opportunity after that has been done which the circumstances demand or the benevolence of the practitioner may prompt him to do without definite expectation of reward.

"THE MEDICINE AND DOCTORS OF HORACE."

UNDER the above heading Dr. Eugene F. Cordell contributes a long and scholarly article to the August number of the *Bulletin of the Johns Hopkins Hospital.* Considering the small size of the volume formed by the extant works of Horace, his references to matters medical are fairly numerous He uses the word "medicus" nine times and mentions a considerable number of pathological conditions. As regards medical treatment, he refers only to "fomenta," baths, and six medicinal plants—namely, malva (mallow), lapathum (sorrel), elleborum (hellebore), abrotanum (southernwood), cicuta (hemlock), and papaver (poppy) The last line of the "Ars Poetica," the poem which is placed last in most if not all of the editions, is:

> Non missura cutem, nisi plena cruoris, hirudo.

Dr. Cordell states that the leech was first recommended by Themison, a contemporary of Horace, as an addition to the materia medica, but is not found in the extant writings of Celsus. Horace mentions by name two physicians, Antonius Musa and Craterus. After an outline of what has come down to us relative to these practitioners Dr Cordell goes on to what is, from an historical point of view, the most interesting portion of his article—namely, a discussion as to whether the Celsus of Epistle i., 8, Epistle i., 3, and the Celsus Albinovanus of Epistle i., 8, are not, in fact, identical with A. Cornelius Celsus, the medical writer This theory seems to have been first brought forward and championed by Giovanni Ludovico Bianconi in his "Lettere sopra A. Cornelio Celso scritte dal Conte Ludovico Bianconi al celebre Abate Girolamo Tiraboschi," published in 1779 These letters, which are 12 in number, have been reprinted in the second volume of the edition of Celsus brought out by Dr. Salvatore de Renzi of Naples (vol. i., Latin, in 1851; vol. ii., Italian, in 1852), where they fill 82 large pages. Bianconi's theory is discountenanced by Orelli, the commentator on Horace, but is upheld by Targa, the commentator on Celsus, and by Sprengel in his "History of Medicine." Bianconi's "Dissertatio de Celsi Aetate" is contained in the editions of Celsus by Targa published in Leyden in 1785 and in Cologne in 1806. In a German version of the Epistles of Horace by Carl Passow (Leipsic, 1833) Celsus Albinovanus is translated "Celsus of Albinova," a rendering which Dr. Cordell considers to be at least plausible, although Albinova is not known as a geographical name.

DANYZ'S VIRUS AS A DESTROYER OF RATS.

AN investigation has recently been undertaken under the direction of Dr. M. J. Rosenau, assistant surgeon U.S. Marine Hospital Service, at the Hygienic Laboratory, Washington, D.C., of which he is director, to test the efficacy of the cultures of bacillus typhi-murium which Danyz recommended for the destruction of rats. An article by Danyz descriptive of his method appeared in the *Annales de l'Institut Pasteur* for April, 1900. Dr. Rosenau found out that a large primary dose of the virus proves fatal but that a small dose is uncertain. The virus as a destructive agent, like a chemical poison, depends for its effect upon the amount ingested. A rapid deterioration in virulence occurs when it is exposed to the action of air and light or when it becomes dry, as is very apt to happen when laid out for rats in the wild state. Against this the virus has a very decided advantage over the usual chemical agents used to kill rats that in so far as is known it is harmless for man and domestic animals. On the whole, the investigations conducted by Dr. Rosenau do not appear to have shown that this virus is likely to prove of any special value as a rat destroyer on a wholesale scale.

THE DISPOSAL OF POULTICES AND OLD DRESSINGS AT THE LONDON HOSPITALS.

ON Sept. 10th a letter appeared in the *St. James's Gazette* from an anonymous correspondent on the subject of the use of pigs' flesh as food being the means of spreading disease, especially cancer. The writer stated: "I was recently told by a friend of mine, who personally inquired of some bargemen on the Thames what the substance was which filled the barges, that they told him it was composed of poultices from London hospitals, which went by barge down the Thames to the Medway to feed the pigs, which eventually became what is known as 'dairy-fed' pork!" This is a grave accusation to make against the London hospitals, and seems to be another phase of the scare started by an evening contemporary in August last, and commented on in the *City Press* of the 21st of that month. It was then stated that there was a great risk of typhoid fever being spread owing to the fact that St. Bartholomew's Hospital dressings were carted promiscuously through the streets of the City on the way to Letts' Wharf, where they are destroyed in the furnace. This charge has been refuted, and as a proof of the precautions taken it is stated that not one of the men engaged in the work has ever suffered from disease. We have made inquiries at the great London general hospitals, and have received what is practically the same reply from all. We are informed, as we knew that we should be, that the invariable practice is to collect the used poultices and dressings and to take them direct to a destructor, where they are completely consumed, being reduced to dust and clinker which are taken away eventually by the parish authorities. It seems to us a great pity that benevolent institutions should be libelled in the press by anonymous correspondents.

THE opening of the new Pathological Laboratory of the University of Oxford will take place on Saturday, Oct. 12th, at 3.30 P.M. Sir William Church, Bart., President of the Royal College of Physicians of London, Dr. G. Sims Woodhead, Professor of Pathology in the University of Cambridge, and others will take part in the proceedings.

THE annual meeting of the Continental Anglo-American Medical Society will be held at Paris on Tuesday, Oct. 8th, at 5 P.M., at the residence of Dr. Bull, 4, Rue de la Paix. The annual dinner of the society will be given at the Hôtel Ritz on the same evening at eight o'clock, when Sir James Crichton-Browne will preside.

A MEETING in support of Dr. J. G. Glover's candidature for election to the General Medical Council has been called for Friday, Oct. 4th, at 8.15 P.M. It will be held at the residence of Dr. E. A. White, 1, Highbury-place, N. Dr. Glover will make a statement and Sir Thomas Barlow, Dr. Danford Thomas, and others will take part in the proceedings.

AT the introductory lecture at the opening of the Winter Session at the Royal Veterinary College, which will be delivered by Dr. E. M. Crookshank on Tuesday, Oct. 1st, at 12 noon, Mr. Albert Brassey, M.P., will occupy the chair.

WE have received the report for the year ending Dec. 31st, 1900, of the Principal Medical Officer of the Uganda Protectorate. The report is of great interest.

THE ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS FOR THE YEAR 1900.

[FIRST NOTICE.]

THE annual report of Dr. Arthur Whitelegge, the Chief Inspector of Factories and Workshops, is published in the form of a Blue-book consisting of over 660 pages. It contains a large amount of interesting information, and shows very clearly the magnitude of the work which is entailed in carrying out the inspections necessitated by recent laws passed chiefly in the interests of the industrial classes.

The arrangement of the items of information given in the report is the same as that which was adopted last year. The body of the report is divided into three parts. There is in the first place a general summary of the work done. This is written by the chief inspector. It consists of about 20 pages, including tables, and is followed by 22 voluminous appendices (pp. 25–153). The second part consists of sectional reports made respectively by the superintending inspectors, the principal lady inspector, the examiner of particulars, the inspector under the Cotton Cloth Factories Acts, the engineering adviser, and the medical inspector (pp. 154–506). The third part consists of tables (pp. 507–664). There is a table of contents, consisting of one page only, but there is no index. This omission very much diminishes the value of the report as a work of reference and must necessarily cause great loss of time to anyone who may wish to investigate one particular subject dealt with in the report, for the information in many instances will be found scattered through the book, and it requires diligent search and the expenditure of much time to collect it. The staff of inspectors of factories and assistants consists of a chief inspector, a deputy chief inspector, five superintending inspectors, a medical inspector, an engineering adviser, over 70 inspectors, and a large number of assistant inspectors. The cost of the travelling expenses alone of these officers amounted to over £10,000 for the year 1900. In these circumstances it seems wasteful that the valuable results obtained by this large staff should not be published in a readily useful form, that is to say with a full index.

During the year 1900 the number of factories on the district registers amounted to 95,664, showing an increase of 4093 for the year. The number of workshops had also increased to the extent of 3463, and amounted to 137,648. It is interesting to note that there has been an increase in the number of laundries in which power is used to the extent of 237, whilst the number of those without power has been diminished by 536 But, still, at the end of the year 1900 it appears that the number of hand laundries was considerably more than double that of those of newer fashion, (the exact figures being 1804 and 4972).

The number of places at which inspections had to be made under special rules was 7529. There are altogether at the present time 23 branches of industry for which special rules have been drawn up for the protection of the workers. The works which are carried on under these rules are as follows: (1) white lead; (2) red and orange lead; (3) yellow lead; (4) lead smelting; (5) paints, colours, &c.; (6) enamelling iron plates; (7) turning and enamelling iron hollow ware; (8) turning and enamelling metal hollow ware; (9) lucifer matches; (10) earthenware and china; (11) making of transfers for earthenware and china; (12) explosives (where nitro-benzole is used); (13) chemicals; (14) bichromate; (15) electric accumulator; (16) yellow chromate of lead; (17) brass; (18) aerated water; (19) wool-sorting; (20) wool-combing; (21) vulcanising of indiarubber by means of bisulphide of carbon; (22) flax working; and (23) humidifying textile factories.

The public attention which was directed some time ago to the disastrous effects of phosphorus poisoning amongst the people engaged in the manufacture of lucifer matches appears to have been the indirect means of causing a falling off in the trade. Amended special rules were drawn up for the regulation of the works in which yellow phosphorus was used. These rules were established as the result of arbitration in the case of the London factories, and were afterwards adopted in the case of 18 other works. Of these factories eight have since been closed and two have discontinued the use of yellow phosphorus. During the year 1900 it appears that only three cases of phosphorus poisoning were reported and none of them proved fatal.

A very great benefit has of late years been conferred on the workers in textile fabrics by the enforcement of what is usually called the "particulars clause," a statutory provision made to secure for the workpeople full and correct particulars of the work which they were required to do and a statement of the amount to be paid for such work. Before this simple act of justice was made a legal obligation, it was a common practice in some places for the employers to defraud their workpeople to the extent of from 12 to 18 per cent. "Previous to the passing of this section," according to the report of Mr. T. Birtwistle, Her Majesty's Examiner of Particulars, "it was very common in certain parts of Lancashire for 36's and even 38's twist to be delivered to the winders and described as 32's and paid for as such; hence the winders (females) in such cases were performing more work than they were paid for. This," he adds, "to some extent applied to almost every branch of the textile trade, but not in the same degree as in the case of the winders, except it may be said that the weavers in a certain district of Yorkshire were almost as badly off." There are now 6227 textile factories in the United Kingdom and 1083 textile workshops in which piece-work rates are wholly or partially paid. During the year 1900 4787 visits were made to textile factories and 1619 to textile workshops, but the Examiner of Particulars found it necessary to lay no more than 20 informations against the employers for neglect in carrying out the regulations which it was his duty to supervise. A conviction was secured in every case in which proceedings were taken, but the average amount of the penalty inflicted amounted to no more than 7*s.* 9 6*d.*—a fact explained by Mr. Birtwistle as probably being due to the fact that the offences were chiefly those of omission and due to carelessness. The number of cases in which legal proceedings have been instituted for offences under the "particulars" section has gradually diminished; in 1898 it was 47, in 1899 it was 30 The examiner concludes his extremely lucid and satisfactory report by saying, "Now we rarely find the particulars of the work deliberately omitted or supplied incorrectly."

It is perhaps not generally known that the manufacture of aerated water is attended by considerable risk to those engaged in the process. During the year 1900 159 accidents were reported, and in one case death was caused. The danger arises from the bursting of the glass vessels into which carbonic acid gas is introduced at a high pressure, and serious accidents frequently occur from this cause. It has long been the practice in some factories to insist that the workers engaged should adopt some protection for their eyes, and "goggles" or masks have in some places been in general use. Some of the workers, however, strongly objected to the use of the instruments of protection which were provided for them. The objection to the use of the guards proceeded entirely from those for whose benefit they were ordered. They alleged that injurious effects on the sight were induced by their use A special inquiry was undertaken to investigate this question, and Mr. Simeon Snell, ophthalmic surgeon to the Sheffield Royal Infirmary, was engaged to make a report on the matter. In the course of his inquiry he visited 17 factories, at which something like 3500 men were in the aggregate employed. It seemed that in the factories in which discipline was generally good there was no difficulty in enforcing the wearing of protectors. In large factories a knowledge of the danger of their occupation was usually appreciated by the workers, for accidents were not of infrequent occurrence. At one large factory, however, although protectors had "in a way" been in use for from 20 to 30 years, it happened that when the Home Office issued special rules making their use compulsory the men declined to wear them. Dr. T. M. Legge and Mr. Snell made in this case a very complete inquiry into the reasons which led the workmen to object to the use of the protectors. They found, in the first place, that a fair trial had not been given to them, but that in many instances their use had been rejected after they had been worn for such short periods as one and a half hours, one hour, or even half an hour. Amongst the complaints were that "a heated sensation over the eyes" was produced and several men complained of headache. One found that when he took off the covering "things danced before his eyes." More than one complained of aching of the eyes and one that after removal of the mask he noticed "a mist before his eyes." No defects of vision were found and it became evident, as a result of the inquiry, that the symptoms complained of were subjective. Careful investigation also proved that in the present conditions of the trade both glass bottles and syphons are liable to burst. New bottles are more liable to burst than those which have been previously used. As a result of a careful enumeration specially made at a large factory Mr. Snell was informed that out of a total quantity of 222.520 bottles filled 1608 had burst The amount per cent. of bottles which burst is, it is true, a small one, but the inquiry showed that it amounts to something like 1 per cent. The only means by which a workman can be protected from the risk of injury is by wearing a mask or shield, and the following summary gives the results of Mr. Snell's investigations:—1. There is an absence of evidence of injury to eyesight from the use of protectors, on the contrary, there are numerous instances of operatives making no complaint after using protectors for 20, 30, or even 40 years. 2. At the factory at which most complaints had arisen as to the protectors it was found that no real use had been made of them in the way that was daily the practice in other similar factories. 3. The occupation, in consequence of the frequency of bottles bursting, is one very prone to accident, the danger not being confined to the fillers All the workers and visitors to the place where bottles are being filled, labeled, or stacked are liable to injury. Bottles placed in boxes, stacked, or being moved on trolleys should be covered with cloth or sacking. 4. Eye "goggles" do not afford sufficient protection. The masks at present in use admit of improvement; the meshes should be fine so as to prevent fragments of glass passing through, and in view of the possibility of injury to the vessels of the neck they should be connected with a leather collar or be continued downwards to afford protection to the neck and its vessels They should be as light as possible and fit without undue pressure. A recently devised shield which, resting on the shoulders, leaves the face free behind it is being brought into use and appears to be in some ways an improvement on those generally in use.

Miss Anderson, the chief lady inspector, very justly gives fully the report of Miss Squire on the accidents and application of special rules in aerated water works. Her observations were exhaustively and cleverly carried out and she has brought to light some things which appear to have escaped the vigilance of other observers. The total number of reported accidents does not, she avers, correctly represent the number of accidents which occur, and this for more than one reason. In the first place, according to the regulations an accident, to be "reportable" must cause an injury which prevents the sufferer from carrying on his work for five hours on any one of the three working days following the accident. "A comprehensive view of the meaning of 'ordinary work' is," Miss Squire believes, "frequently taken in aerated water works, where it is commonly said that the worker must do as the foreman tells her. Such a case," she continues, "I brought before the magistrates who said that inasmuch as the injured person's occupation was altered by her accident it was reportable." Again, many painful accidents happen which are not sufficiently serious to prevent the victim from shortly resuming work and the hands of bottlers and wirers usually show cuts and scars in all directions. Miss Squire thinks that a perfectly satisfactory gauntlet has not yet been invented. The face-guards supplied to girls have often been entirely unsuitable; when those provided are light in weight and clean she has found little opposition to their use by the workers. Some of the guards supplied have been either "heavy fencing masks, men's size," or have had no proper means for fixing them on the head. In one case Miss Squire found all the girls wearing them on the tops of their heads. The manager showed the special rule notice as to wearing the protectors but pointed out that there were no directions as to *where* they were to be worn. The protectors were old and dirty, they could not be worn on the face without flattening the nose, and "no self-respecting woman would put her face into one"; moreover, even a self-respecting woman would be unable to see if she did put her face into one, such was the faultiness of their construction. Fortunately, in the case of this factory matters were subsequently improved and every girl was found on a future visit to be wearing a protector in a proper manner. It cannot be too strongly insisted on that glass bottles charged with carbonic acid at a high pressure are a constant source of danger to all those who are brought near to them.

THE GLASGOW INTERNATIONAL EXHIBITION.

(FROM OUR SPECIAL COMMISSIONER.)

AFTER the great International Exposition held at Paris last year the small exhibition at Glasgow this year affords at least this advantage—namely, that it is possible to see the whole of the exhibits at the latter place, while in the former such a task was beyond the strength of any human being. Indeed, the growth in size of international exhibitions—and in this matter Glasgow follows the general rule—is a serious obstacle to the holding of such exhibitions of the world's produce. In 1889 the total admissions to the Paris Universal Exhibition amounted to 30,350,297 and in 1900 to 50,859,955. At the Glasgow International Exhibition of 1888 the total admissions were 3,975,904; this year the admissions up to Sept. 20th have been 7,815,675 and they may reach 9,000,000 before the exhibition closes. Thus the proportionate increase is even greater in Glasgow than it was in Paris. From both the moral and the health point of view the gathering together of so many people in the Exhibition grounds is an important factor. In the evening the admission is only 6*d.* and a large number of the poorer classes are drawn from the public-houses to the Exhibition. Here there is less drinking, for they are enjoying the bands, the illuminations, and the fireworks. There are also a great number of bungalows with sheltered terraces where tea, excellent French pastry, and other light refreshments are provided at moderate cost. Great crowds thus sit out in the open air, and being exposed to public view they are more inclined to behave themselves. This is much better from the moral and the health point of view than the comparative privacy of a public-house bar, while intellectually the exhibits themselves are object-lessons. The great increase in the number of visitors as compared with the last exhibition held in Glasgow demonstrates that these advantages have been widely appreciated. In the softening of the manners of the rougher sections of the population, in the reduction of the amount of whisky drunk, and in providing more elevating and refining means of relaxation and enjoyment, the Exhibition has been an unalloyed benefit to many hundreds of thousands of poor people.

In regard to the educational influence of the Exhibition, however, it is to be regretted that its international character has not been well supported. It does seem as if the Exhibition has suffered from a tacit boycott. Russia and France alone make a respectable show, Japan comes next with some very beautiful art objects, and there is a very small Austrian section; but German art, science, and industry, which were so very prominent at Paris last year, are unrepresented. There are a few isolated individual exhibits from various nationalities, such as the ever-present Van Houten's cocoa from Holland, a few rugs and curios from Persia and Morocco, and a little furniture and art pottery from Denmark, but practically speaking, there are only two foreign sections worthy of the name, those of France and Russia. Neither of these contains anything of special interest from the medical or sanitary point of view. There are perhaps half a dozen chemical exhibitors in the French section, but perfumery, such as that of the celebrated firm of J. Simon, is more prominent than pharmaceutical products. La Compagnie Générale d'Eaux Minérales, 13, rue Taitbout, Paris, exhibits some of the best known mineral medical waters of France, but the surgical instruments for which French manufacturers have acquired a reputation were missing. On the other hand, there are a good many French wines, alcohols, and preserved fruits, vegetables, that are of interest from a health point of view.

What attracts visitors most in the Russian section is the large and original pavilion containing the exhibits of the Russian department of woods and forests. The development of the wood industry in Scotland would be of great benefit. Close to Glasgow the barren hills that slope down to the numerous lochs and tributaries of the Clyde might well be planted with trees. These, in the course of time, could be cut and slid down to the water below, tied together into rafts, and towed to the great neighbouring centres of industry. This would supply very healthy winter outdoor work and help to reconstitute physically a race that is being seriously deteriorated by town life and work in factories.

On entering the Exhibition by the main entrance the Russian and French sections are immediately to the right. Passing the Russian furs, bronzes, and furniture, we come to the sanitary section. The exhibits here are not numerous, but they are good as far as they go. The first reached are those of Messrs. Twyford, Limited, who, among many other things, show a new hospital bed-pan and urinal bottle-sink. There are flushing-pipes on which the bottle and pan are placed upside down, and by pressing on a pedal below the sink they are scoured out. A third pedal flushes out the entire sink. This obviates any soiling of the hands. In regard to baths most of the manufacturers seem to have been impressed with the danger of scalding the patients. Such an accident did occur recently. The idea is that the protests or complaints of a patient, especially if of unsound mind, may be attributed to his unwillingness to take the bath, while in reality they are due to the over-heated condition of the water. Hence there are various attempts to provide a bath where the heat of the water shall be automatically regulated and the risk of accident through the carelessness of attendants obviated. Messrs. Twyford's patent asylum bath fitting has no handles. A key is employed to turn on the tap, but the aperture for inserting the key to turn on the hot water is covered over, and this cover can only be removed by turning on the cold water. The hot water must therefore be mixed with cold as it enters the bath. The Stockport surgical lavatory shown by this firm differs from other lavatories, inasmuch as it stands independently and free from support four inches away from the wall. It can thus be washed and kept clean behind as well as in front. The detachable metal screw cone employed by this firm to join closet-pans to soilpipes is a very useful contrivance. Being of gun-metal it cannot wear out and may be used over and over again. It joins pipes together in a moment and it may be as rapidly undone. No cement is employed and the joint is perfectly air tight by reason of its accurately fitting cone shape and the pressure of the screw fastening Messrs Twyford have also a revolving pathological table made of one single block of enamelled hardware, the surface of which is fluted for draining purposes The table stands and revolves on a large central pedestal, and round the base there is a circular open drain over which the pipe from under the table discharges the water coming from the surface. This is well adapted to post-mortem examinations Nor should it be omitted to note that all the hardware of this firm is said to be made of leadless glaze and thus its manufacture does not endanger the health of the workers

Next to these exhibits are the very large stands of Messrs Doulton and Co, Limited, comprising art pottery as well as sanitary hardware Most of the exhibits shown here were described last year in the columns of THE LANCET when speaking of the Paris Exhibition, where Messrs. Doulton were appointed members of the jury and attained the highest possible distinction This firm also puts on the market bath fittings with valves that can be so arranged that the water cannot exceed a given temperature. These can be fixed to give any desired degree of heat, but the regulators are then entirely cased up so that they cannot be tampered with in any way Even when the water is turned on very rapidly no concussion is produced, the valves close gradually and therefore there is no risk of breaking the joints Of course there are also specimens of the closets, the sinks, the lavatories, the urinals &c, for which Messrs Doulton have a world-wide reputation.

On the other side of the passage are the exhibits of Messrs Shanks and Co, and they also have a bath where the water is turned on by a handle that moves round a dial from "shut" to "cold," then to "tepid" and to "hot." Here it stops and must be moved back to "shut." The valves can be regulated to suit the pressure and the desired heat is thus obtained. There are likewise some syphonic silent closets in which the surface of the water is larger than the aperture of the seat and therefore the sides of the pan cannot be splashed Messrs Shanks also show an elegant model bath-room where all the fittings are of glass and nickel Next to them, Messrs. Buick and Son of Alloa near Stirling, have a variety of sanitary ware, but they are of well-known models which present no new features. Finally, there are working models of the Exeter septic tank with the alternating gear by which the sewage from the septic tank is discharged first into one filter and then into another Here the system can be studied in its practical application, while on shelves there are bottles containing samples of the filtrate I was informed that some 450 schemes for the disposal of sewage on this system have been prepared, and 120 carried out.

Close by the sanitary section are the exhibits of the colonies of Rhodesia and Queensland and of women's industries The latter are of interest to those who consider the employment of women not only as a social but also as a sanitary problem In this latter respect it is pleasing to note how numerous and varied are the light and artistic forms of work for which the physique of women is well suited Some Indian exhibits, Ceylon teas, and the French section fill up the remaining space of this side of the main building On the left side of the main entrance nearly all the exhibitors are British or colonial Here the principal things from the health point of view relate to food supply, such as Quaker oats, biscuits of all sorts, infant foods, and invalid foods Of course, Messrs Brand and Co are prominent in this section, distributing meat lozenges to hungry visitors; while the samples of protene and of plasmon with a little Mellin's food and a cup of bovril, which can be obtained for the asking would suffice as a substitute for lunch to any curious and bold investigator bent on testing the merits of these well known commodities The wines include Glendenning's port wine mixed with beef extract and malt The well known vintages from Australia hold a prominent place There are notably the Vifera brand and the Orion brand which have been analysed in THE LANCET Laboratory with good results The more these wines are exhibited and known the better, for they are wholesome and preferable to alcoholic liquors which are often not so pure or safe

From the main building a long gallery leads to the machinery hall This gallery contains the shipbuilding exhibit which constitutes one of the most remarkable and successful features of the Glasgow Exhibition, though it is out of the province of these criticisms By the side of these temporary structures a permanent red stone palatial building will remain as the Glasgow Palace of Arts There are here some fine sculptures and an extensive collection of English paintings It is unfortunate that there should be so few foreign paintings in these fine art galleries Close by the art section in the grounds, there are some field ambulances and a tortoise-shell tent capable of holding 10 beds, fully equipped. Here are folding water proof cloth hand basins and buckets and folding chairs tables, &c., all very light and transportable The stretchers are provided with rollers so that they can serve as beds in an emergency and can be pushed along while the patient is lying upon them The portable stove has a flue that divides and can therefore be readily packed Next to this there is an officers' tent and finally Messrs Humphreys's tin and wood base hospital The tables are of enamelled iron with glass slabs There are louvre windows on either side of the ward and also in the pointed roof

Crossing the river Kelvin, which winds through the Exhibition grounds, a square building is reached devoted to heating and lighting The first thing which is seen on entering is a long array of open fire grates, mostly on the Teale principle and by the door there is an historical arm chair These are exhibits of the Carron Co., who in 1801 built the *Charlotte Dundas*, the first steamship ever floated It was employed as a tug on the river Clyde, the armchair is made from the wood of this vessel This firm now own the Carron line of steamers, but their principal business relates to heating and lighting They have kept well up to the times both for coal grates and gas stoves. They have even a drawing room grate which revolves; on one side a coal fire can be lit and if the other side is brought forward then a gas fire can be ignited Their gas cooking stoves, large and small, are so contrived that all the fittings therein can be easily taken out and thoroughly cleaned One of their open grates is composed of tubes carrying air under the fire, then up behind, and out by the mantelpiece thus stimulating the circulation of the air in the room and warming it at the same time

The Richmond Gas Stove and Meter Co have also a very large display The burners of their gas stoves are readily lifted off, so that they can be dipped into hot water and cleaned Messrs Fletcher, Russell, and Co exhibit the Waverley inlet ventilator The air is not admitted in a direct line but is thrown upwards and deflected downwards on a copper gauze. By such means a direct draught is obviated They have also Bunsen burner irons, which are clean and economical and avoid the using of unwholesome coke stoves in workrooms. For baths they can heat two gallons of water to 50° F in one minute The cost in gas for heating a large bath would rarely exceed one penny Messrs R and A. Main and Co have Bunsen burner stands on which irons can be placed and heated in three minutes sufficiently for ironing during 10 minutes, these would consume one pennyworth of gas in eight hours Here, again is another method of improving the sanitation of the workshop. Messrs Smith and Wellstood, Limited, show the improved and convertible open and close fire range which they are supplying to the Glasgow Improvement Trust which manages the cheap tenements built by the corporation for the poor of that town. They are 36 inches in length and cost £3 16s, but they are not provided with boilers Such are the principal exhibits of interest to the sanitary reformer They are not numerous, but they present some interesting features

Apart from sanitation the Exhibition itself is well worth a visit. A visitor need not fear, as was the case in Paris last year that he will have to leave before seeing half of the exhibits he would have liked to examine The Exhibition is small enough for a visitor to see all that is likely to be of interest to him in the course of a few days particularly as there is an almost complete absence of side shows to lead him astray from his main purpose The great increase in the number of visitors as compared with the last Exhibition held in Glasgow shows how much the present show has been appreciated and the citizens are to be congratulated on their success

ASYLUM REPORTS

Warwick County Asylum (Annual Report for 1900).—The average number of patients resident during the year was 948 and comprised 384 males and 554 females The admissions during the year amounted to 224 of which 103 were males and 121 were females Of these 190—viz 82 males and 108 female—were first admissions Dr Alfred

Miller, the medical superintendent, states in his report that among the admissions were the following incurable cases—viz., 13 idiots, 17 epileptics, 11 general paralytics, and 28 cases of chronic insanity. "It will be seen from the above figures that one-third of the number of cases admitted had no chance whatever of recovery and naturally among the remainder a large number will turn out incurables." Dr. Miller adds that "idiots and epileptics should certainly never be received into county asylums to associate with curable cases. What can be more detrimental to recovery from mental disease in pregnancy than the constant and trying association with patients such as the above?" The number of patients discharged as recovered during the year amounted to 72—viz., 37 males and 35 females, or 7·5 per cent. of the average number resident. The deaths during the year amounted to the same number—viz., 72, composed also of 37 males and 35 females, or 7·5 per cent as calculated on the same basis. Of the deaths three were due to senile decay, eight to pneumonia, nine to cerebral hæmorrhage, nine to phthisis and other forms of tuberculosis, 12 to general paralysis, 16 to epilepsy, and the rest to other causes. A plan for two isolation blocks for male and female phthisical patients having been sanctioned by the Commissioners in Lunacy the buildings are in process of erection. The asylum has acquired recently an adjoining farm on a long lease and has been able to improve the dietary of the patients as regards vegetables and eggs. At the time of the report in the preceding year 11 male attendants of the asylum staff were out at the front in South Africa; since then seven have returned and good accounts have recently been received of the rest. "Entering on the twentieth year of my service in the asylum," says Dr. Miller, "I am naturally able to look back on many changes. Great sanitary improvements have been effected and important additions have been made to cope with the increasing number of cases coming under our care. But the most important question I feel bound to ask is: What advancement has been made in our curative methods and what have been their effect on the recovery-rate?" Thirty years ago, when asylum buildings were certainly not what they are at present and the amount of personal comfort supplied was far less, the average recovery-rate, as shown in the reports of the Commissioners in Lunacy, was 11 per cent. of the average number of patients resident. To-day it is barely as much, being but 9¼ per cent. "New drugs have certainly been tried by the score; ...... baths, massage, and electricity have all been successfully used in their turn, and yet our results are no better than at the commencement of the period. ...... Personally, I am led to think," concludes Dr. Miller, "that there will be no material increase in the number of recoveries until there is a more general provision for treating special forms of mental disease in separate buildings. Epileptics, idiots, imbeciles, senile and other incurable cases should be kept apart from the recent and curable cases. The latter class should certainly have buildings set apart for their reception and managed rather on the lines of a hospital where treatment could be carried out under the most favourable surroundings and where patients ...... would not be living in association with those incurables to whom I have alluded." The Asylums Committee state that the weekly charge for maintenance has been raised from 8*s.* 9*d.* per head to 9*s.* 0½*d.* since June 30th, 1900. The Commissioners in Lunacy state in their report that the wards were bright and cheerful, the dormitories were clean and in good order, and the medical case-books were perfectly kept.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6261 births and 3704 deaths were registered during the week ending Sept. 21st. The annual rate of mortality in these towns, which had been 21·0, 19·4, and 18·3 per 1000 in the three preceding weeks, further declined last week to 16·8 per 1000. In London the death-rate was 15·6 per 1000, while it averaged 17·7 in the 32 large provincial towns. The lowest death-rates in these towns were 11·2 in Bristol, 11·6 in Swansea, 11·8 in Derby, and 12·2 in Birkenhead; the highest rates were 20·7 in Bolton, 22·7 in Gateshead, 25·2 in Burnley, and 25·6 in Sunderland. The 3704 deaths in these towns last week included 733 which were referred to the principal zymotic diseases, against 1506, 1256, and 971 in the three preceding weeks; of these 733 deaths, 491 resulted from diarrhœal diseases, 70 from "fever" (principally enteric), 49 from diphtheria, 41 from whooping-cough, 40 from measles, 39 from scarlet fever, and three from small-pox. The lowest death-rates from these diseases last week were recorded in Bristol, Cardiff, Swansea, and Leicester; and the highest rates in West Ham, Salford, Burnley, Sunderland, and Gateshead. The greatest proportional mortality from scarlet fever occurred in Derby; from whooping-cough in Swansea; from "fever" in Plymouth, Nottingham, Salford, Huddersfield, Hull, and Sunderland; and from diarrhœal diseases in Burnley, Sheffield, Hull, Sunderland, Gateshead, and Newcastle. The mortality from measles showed no marked excess in any of the large towns. The 49 deaths from diphtheria included 27 in London, three in West Ham, two in Halifax, two in Sheffield, and two in Hull. Three fatal cases of small-pox were registered in London, but not one in any other of the 33 large towns. There were 153 cases of small-pox under treatment in the Metropolitan Asylums hospitals on Saturday, Sept. 21st, against 74, 92, and 137 on the three preceding Saturdays; 37 new cases were admitted during the week, against 52, 31, and 62 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 3008, 2994, and 3064 at the end of the three preceding weeks, had further risen to 3098 on Saturday last; 427 new cases were admitted during the week, against 303, 346, and 457 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 124 and 116 in the two preceding weeks, rose again last week to 124, but were 48 below the corrected average. The causes of 45, or 1·2 per cent., of the deaths in the 33 towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Leeds, and in 12 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Preston, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·8 and 17·5 per 1000 in the two preceding weeks, further declined to 16·2 per 1000 during the week ending Sept. 21st, and was 0·6 below the mean-rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 7·9 in Perth and 11·3 in Dundee to 20·9 in Aberdeen and 21·3 in Greenock. The 517 deaths in these towns included 53 which were referred to diarrhœa, 13 to whooping-cough, six to "fever," five to measles, four to diphtheria, and two to scarlet fever. In all, 83 deaths resulted from these principal zymotic diseases last week, against numbers decreasing from 174 to 74 in the seven preceding weeks. These 83 deaths were equal to an annual rate of 2·6 per 1000, which was 0·7 below the mean death-rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had declined from 129 to 38 in the six preceding weeks, rose again last week to 53, of which 24 occurred in Glasgow, 10 in Edinburgh, six in Dundee, five in Aberdeen, four in Leith, and three in Paisley. The deaths from whooping-cough, which had been 13 and 10 in the two preceding weeks, rose again to 13 last week, and included seven in Glasgow, three in Edinburgh, and two in Leith. The fatal cases of "fever," which had been six and 12 in the two preceding weeks, declined again last week to six, of which five were registered in Glasgow. The deaths from measles, which had been eight in each of the two preceding weeks, decreased to five last week, and included two in Glasgow and two in Edinburgh The four fatal cases of diphtheria, two of which were registered in Glasgow, showed a slight increase upon the numbers recorded in recent weeks. The deaths referred to diseases of the respiratory organs in these towns, which had been 60 and 79 in the two preceding weeks, further rose last week to 81, but were 20 below the number in the corresponding period of last year. The causes of 24, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·5, 20·6, and 22·2 per 1000 in the three preceding weeks, further rose to 23·4 per 1000 during the week ending Sept. 21st. During the past four weeks the death-rate has averaged 22·4 per 1000, the rate during the same period being 16·8 both in London and in Edinburgh. The 168 deaths of persons belonging to Dublin registered during the week under notice were 8 in excess of the number in the preceding week, and included 30 which were referred to the principal zymotic diseases, against 35, 35, and 25 in the three preceding weeks; of these, 20 resulted from diarrhœa, four from whooping-cough, three from "fever," two from diphtheria, and one from scarlet fever. These 30 deaths were equal to an annual rate of 4·2 per 1000, the zymotic death-rates during the same period being 2·6 per 1000 in London and also in Edinburgh. The fatal cases of diarrhœa, which had been 28, 29, and 22 in the three preceding weeks, further declined last week to 20. The deaths from whooping-cough, which had been one, two, and one in the three preceding weeks, increased to four last week. The mortality from "fever" exceeded that recorded in any recent week. The 168 deaths in Dublin last week included 47 of children under one year of age and 32 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight excess over the respective numbers in the preceding week. One death from violence and five inquest cases were registered during the week; and 59, or more than a third, of the deaths occurred in public institutions. The causes of six, or nearly 4 per cent., of the deaths in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are announced:—Fleet Surgeon H. S. R. Sparrow to Pembroke Dockyard. Staff Surgeons: W. G. K. Barnes to the *Formidable* and J. Donnell to the *Empress of India* and to the *Cæsar* on recommissioning. Surgeons: A. F. Fraser to the *Formidable*; W. R Center to the *Ramillies*; and R. Kirby to the Chatham Hospital. Civil Practitioner J. Owen to be Surgeon and Agent at Goodwick.

ROYAL ARMY MEDICAL CORPS.

Captain H. L. G. Chevers, retired list, is selected for service with the troops in South Africa. Lieutenant H. W Long has arrived in the Eastern District for duty. Lieutenant W. C. Stevenson and Lieutenant M. C. Beatty are posted to the 3rd Station and Cambridge Hospital at Aldershot. Lieutenant McAllum is attached to the Cambridge Hospital at Aldershot for duty. Lieutenant R. V. Cowey is under orders for India. Captain I. A. O. MacCarthy is transferred from the Poona District to the Aden District, and Lieutenant G. E. Leary from the Mhow District to the Aden District. Colonel M. O'Connell, Principal Medical Officer, Peshawur District, is transferred to the home establishment. Major L. Heywood takes over medical charge of troops, Station Hospital, &c., Portland. Captain H. D. Mason assumes medical charge of the Royal Artillery, Mounted Infantry, Royal Engineers, District Staff, and details, Marlborough Lines, Aldershot. Captain J. H. Power is appointed for duty with the Royal Horse Guards at Windsor.

N.B.—The date of the grant of the local rank of Colonel to Lieutenant-Colonel W. A. May whilst Principal Medical Officer of a division in South Africa is Jan. 19th, 1900, and not as stated in the *London Gazette* of Nov. 2nd, 1900.

The undermentioned officer of Lord Strathcona's Corps is, on the disbandment of the corps, granted honorary rank in the Army with permission to wear the uniform of the corps. Dated March 16th, 1901.

Temporary Captain C. B. Keenan, D.S.O., Medical Officer, to be Hon. Captain.

VOLUNTEER CORPS.

Artillery: 8th Lancashire: Surgeon-Lieutenant J. D. Wright resigns his commission.

Royal Engineers (Volunteers): 1st Middlesex: Surgeon-Lieutenant H. M. Macnaughton-Jones resigns his commission.

ARMY MEDICAL SCHOOL, NETLEY.

The eighty-third session of the Army Medical School will commence on Wednesday, October 2nd. The session will be attended by 25 surgeons-on-probation for the Indian Medical Service and two for the Royal Army Medical Corps. The following is a list of those entering the school:—

INDIAN MEDICAL SERVICE.

A. E. J. Lister.
T. F. B. Williams.
S. H. L. Abbott.
A. W. Greig.
R. E. Lloyd.
J. Woods.
H. B. Steen.
D. Munro.
E. Bisset.
J. E. Clements.
A. W. Overbeck Wright.
R. J. Bradley
E. A. Loch.
R. M. Carter.
R. L. Hagger.
D. G. R. S. Baker.
T. W. Harley.
J. W. McCoy.
R. A. Willcocks.
T. G. F. Paterson
D. G. Ral.
R. M. Barrow.
W. R. J. Scroggie.
J. R. J. Tyrrell.
L. P. Farrell

ROYAL ARMY MEDICAL CORPS.

B. A. Craig.
C. T. R. White.

SOUTH AFRICAN AFFAIRS.

There have been several untoward events recently in South Africa arising out of a recrudescence of highly enterprising activity on the part of the Boers. Whatever importance these may have from a military point of view, they possess little or no medical interest beyond the fact that besides entailing a lamentable loss of life they lead to an increased number of surgical cases in our hospitals and to the belief that every temporary success on the part of the Boers can only have the effect of prolonging the sufferings caused by the war. In the reverse at Blood River the losses sustained by Major Gough's force amounted to three officers and 17 men killed, three officers and 28 men wounded, and five officers and 272 men captured, a total of 328. In the case of the 17th Lancers the fighting was more severe and the losses among the troopers in killed and wounded, relatively to the number engaged, were much heavier.

According to the last weekly report received from Lord Kitchener the wearing-down process steadily goes on, the notable feature being the number of Boers captured and the losses on the part of the Boers in the way of ammunition, vehicles, horses, and cattle, as compared with the number of Boers returned as killed and wounded or surrendered There are no sick returns of their forces available, and we have not, nor have we ever had throughout the campaign, any means of knowing what their losses from disease have been There is still, considering the season, much enteric fever among the British forces, however, as may be seen from the published sick returns.

DEATHS IN THE SERVICES.

Lieutenant-Colonel James Moran, I.M.S., on Sept. 20th, in London. He entered the service in 1875 and served in Afghanistan in 1878–79 (medal). He was appointed Lieutenant-Colonel in February, 1900

Surgeon-General William Alister Catherwood recently. He was Principal Medical Officer of the Naini Tal District.

Correspondence.

"Audi alteram partem."

"WAS LUIGI CORNARO RIGHT?"

To the Editors of THE LANCET.

SIRS,—I should be gratified to think that Dr. Cameron Kidd is right in assuming that medical men are fully alive to the necessity of thoroughly exercising the infant's jaws and teeth by mastication. Be this as it may, it is certain that the young human does not adequately exercise his jaws; did he do so we should not see so many cases of defective development. Dr Kidd holds, and claims that medical men in general hold, that in order to secure adequate exercise of the teeth we should rely on "artificial exercise of the jaws" rather than on the mastication of food. This view is, I [illegible] I do not for one moment conte[illegible] cords, and the like, may not h[illegible] not a rodent; his teeth are essentially for the purpose of biting food, and not for gnawing hard non-nutrient substances, like a mouse or a rat. Dr. Kidd argues that the child only spends about an hour over his meals every day, and that this time is inadequate for the proper development of the jaws. Well, an hour's good exercise of the jaws every day would, I believe, go a long way towards securing their normal development; unfortunately, however, the child's food is generally so pappy that little mastication is required; if it contained more hard and dry ingredients, not only would he have to masticate more vigorously, but he would be obliged to spend a longer time over his meals. There is a further advantage of allowing the child to expend his abundant masticatory energy in chewing food rather than rings and corals which Dr. Kidd appears to overlook. I refer to the fact that the chewing of food prepares it for the stomach. One of the objections I have urged against feeding children too exclusively on paps is that food of this kind is swallowed without being properly insalivated, and, seeing how powerful is the diastasic action of human saliva, this is surely undesirable. Providing food is such that it compels abundant mastication it is astonishing how digestible it generally is, but if we feed our children almost wholly on soft food how can we secure this preliminary preparation by the mouth?

Dr. Kidd points out that one of the dangers of giving small children solid food is that they may choke, but this danger can be reduced to a minimum by taking simple precautions, and it is better to run this remote risk than to subject the child to the certain evils resulting from the employment of too pappy foods. Finally, Dr. Kidd argues (in favour of relying chiefly on artificial means for exercising the child's jaws) that even if he is fed on the food of adults such food does not, on account of its softness, afford proper exercise for them. This is perfectly true and, being true, how grave an indictment against our present system of feeding! The child needs, in fact, food requiring more abundant mastication than that consumed by most adults, and there is no difficulty in obtaining suitable foods of the kind.

To Mr. Sellors "it is not apparent that defective growth of the jaw is due to lack of mandibular exercise." If he will not grant me this I fear I cannot convince him, any more than he can convince me by his mere *ex cathedrâ* utterances—e.g., "Dr. Campbell mistakes the significance of the phenomena attending the commencement of dentition. ...... I regard (*sic*) the flow of saliva. ......" Anxious as I am for light, eager as I am to get at the truth, I cannot accept the mere *ipse dixit* even of Mr. Sellors.

I am gratified to find so competent an authority on dietetics as Dr. Willoughby Gardner joining the crusade against pap-feeding and supporting the view that the present system may have much to do with the production of adenoids. I agree with all he says. The suggestion that the constant use of the rubber teat may be a cause of this affection is worthy of consideration. Dr. Gardner brings out two important points on which we shall do well to dwell: 1. That adenoid disease is more common among us than it was among our ancestors. This is no mere surmise; it can be proved in a very simple way. A large proportion of those afflicted with this disease show defective development of the upper jaw; if, therefore, in a given community such defective development is rare we may be sure that adenoid disease also is rare in it. Now, if we examine the skulls of our ancestors of even a few generations back, we find a low percentage of such defects, just as we do in the skulls of primitive communities—e.g., those in the museum of the Royal College of Surgeons of England. 2. That the disease is met with under the most favourable sanitary conditions in respect of fresh air, warm clothing, abundant food, muscular exercise, "in the houses of the rich and even of medical men," and that it continues to abound in spite of improved sanitation.

I would ask your readers to keep these two cardinal facts clearly before them. What *factor*, we have to ask, is in operation now which was not in operation—or, if so, in a minor degree only—among our ancestors? In seeking an answer to this question one naturally turns to the food, and I myself have little doubt that it is to be found in this direction. Do we adequately realise how greatly our food has changed during the past few generations? While it is more abundant and nutritious than it used to be it is at the same time much softer and more pappy. In my first letter I complained that the food of the young human is too much limited to pap, and that in consequence of this the jaws and their accessory cavities do not properly develop. Defective development of the nasal cavities, the naso-pharynx, and the pharynx must surely predispose them to disease. Consider, further, the influence of mastication on the flow of blood and lymph in the tissues of the mouth and accessory cavities. No lymph flows from the cut lymphatic trunk of a limb when at rest; it is only during rhythmic muscle contractions that the lymph circulates. Hence it follows that vigorous mastication implies a vigorous flow of the lymph in the tissues of the mouth and its accessory cavities, and defective mastication a defective flow. Now, Sirs, I would ask your readers which is the more liable to get adenoids—a child with well-developed buccal, nasal, and pharyngeal cavities, the tissues of which are periodically flushed by a vigorous flow of blood and lymph, or one in whom these cavities are ill-developed and the flow of blood and lymph thereof not stimulated in the normal fashion? Am I chimerical in suggesting that the former is? Am I rushing to extremes in urging our profession resolutely to put its foot down on the uncommon-sense practice of feeding children almost exclusively on squash?

I do not, of course, contend that this is the only factor in the causation of adenoids. The fact that the disease may occur in young infants and even (so it is said) at birth proves otherwise; the causation of even the simplest thing is complex, and no result is produced by a single cause. Mr. Sellors asserts that adenoids are "frequently met with in the first few months of life." Such is not my experience. I am desirous in this connexion of knowing, and I shall be grateful if any of your readers can help me to ascertain, whether the disease is more common in bottle-fed children than in those who are brought up at the breast. I should expect it to be, inasmuch as the former exercise the oral apparatus far less in obtaining their milk than do breast-fed children. I am, Sirs, yours faithfully,

Wimpole-street, W., Sept. 22nd, 1901. HARRY CAMPBELL.

"WORKHOUSE NURSING."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Sept. 21st, p. 813, Dr. F. S. Toogood writes: "My opinion is that with adequate salaries and proper government there would be no lack of good nurses even in our smaller infirmaries." No doubt Dr. Toogood speaks from his own experience, but his opinion is not in agreement with that of some of those whose special work is the inspection of Poor-law infirmaries. One of the general inspectors of the Local Government Board thus reports: "The nursing staffs, at any rate in the larger workhouses, are being slowly strengthened, but the same difficulty still exists in getting nurses who have had thorough training, and I do not think that in this part of England (Durham, Northumberland, North Riding of Yorkshire, and parts of Cumberland) the blame can be wholly laid on the salaries offered or the quarters provided" (Twenty-ninth Annual Report, 1899-1900, Local Government Board, p. 149). Another inspector reports: "The chief obstacles in the way of better nursing continue to be inadequate accommodation for nurses and the rather limited supply of experienced nurses" (idem, p. 126). Another inspector remarks: "The difficulty in obtaining and retaining the services of nurses for workhouses continues to increase" (idem, p. 93). The reports teem with similar observations.

Then, again, there is the question of "proper government." Presumably your correspondent means the interference of masters and matrons with the nursing arrangements. But so long as the sick wards are contained within the workhouse walls so long must these officials have some responsibilities towards nurses, patients, and nursing. The nurses will necessarily be under the master as regards general discipline, and the patients likewise; the nursing will be subject to the matron in respect to the supply of necessaries; and the wards will come under the care of the master as regards repairs and such like. There must, therefore, be relations between workhouse nurses and the higher workhouse officials. The past as well as the present show the practical impossibility of these two sections of the staff working together in harmony. Thus, one of the general inspectors reports: "I regret to have to report friction between masters and matrons on the one part and nurses of the infirmaries on the other. ...... I do look forward to the day when, in workhouses of any size, the infirmaries will be detached." The mere fact that the wards are actually within the workhouses exercises a very bad influence upon the recruiting of nurses and probationers. The subordination of the nurses to their social inferiors is fatal. Yet these things cannot fail to be present in the smaller infirmaries.

Dr. Toogood questions the necessity of having highly-trained nurses in country workhouses. Here he is in conflict with the opinion of Dr A H Downes Medical Inspector of the Local Government Board, who in a memorandum dated April, 1892, makes the following observation ' Humanity and economy alike dictate that the sick poor in workhouse sick wards should receive nursing treatment not less efficient than that which is now afforded in general hospitals and in well administered cottage hospitals.' Later in the same memorandum he remarks " It should always be remembered that although the sick are mostly chronic a large number are of such a kind as to require constant care and attention" It is impossible, therefore to accept Dr Toogood's method of solving the nursing difficulty in country workhouses by supplying the infirmaries with untrained nurses The guardians' efforts to secure trained nurses for their sick wards, *too*, indicate *their* opinion as to the necessity for trained nurses Then as to the difficulty of getting or training nurses A large number of boards of guardians passed important resolutions on this subject in 1900 *With one exception all the general inspectors refer forcibly* to it in their last reports How are trained nurses to be obtained in sufficient quantity from outside? The Poor law service compares unfavourably in attractions with the general hospitals, the nursing *institutions* the district nursing associations and such like It requires a certain amount of special training before outside nurses can be put into responsible positions in workhouses The nurses who have come from general hospitals find their ideals in the way rather than otherwise, and the life is extremely monotonous Except in the higher posts they do not care sufficiently for the service to remain any longer in it than they can help I do not think that it will ever be sufficiently attractive to nurses trained outside to induce many of them to fill the lesser posts Under the present conditions they are strongly repelled from workhouse service

To turn from the nurses to the sick the country workhouses are mostly out of date "It is undoubtedly the case that since workhouses were established under the Poor law Amendment Act 1834 the circumstances connected with the administration of relief and the character of those for whom accommodation in workhouses has to be provided have so materially changed that arrangements originally adequate and in accordance with the spirit of the times have ceased to be so" (Circular letter of the Local Government Board to boards of guardians, Jan 29th 1895) One of the general inspectors in his last report refers to the workhouses in the west of England as being "at least half a century old He says ' There are a good many workhouses in the west where improved accommodation for the sick is much needed and where, I believe, that even if existing rooms were vacated their conversion into sick wards would at best be only a makeshift arrangement and nothing but the erection of a new infirmary on modern lines would give really satisfactory results' (p 111) It is the same all over the country, and *boards of guardians are spending* very large sums annually in trying to improve these ancient structures or in building small infirmaries attached to them, the latter are in nearly every such case too small to train probationers *properly and must be dependent upon* nurses trained elsewhere Dr Toogood says that it is impossible to train probationers in country infirmaries because of the want of suitable training material But lower down *he contradicts this, for he says "The larger infirmaries* can and do train their nurses as thoroughly and as fully as any of the hospitals My scheme is so to combine the patients of the small infirmaries as to form institutions large *enough to be capable of training* probationers Your correspondent says that my scheme would mean the expenditure of millions The *fact* is, however, as I have already shown that boards of guardians are wasting immense sums of money annually *on "improvements'* of the existing buildings or in badly considered new buildings About £100,000 were expended on improving existing workhouse infirmary buildings in 1899 90 Other large sums were spent in *improving some of the separate infirmaries It is time* that parochial politics gave place to the general interests of the Poor law service and that these sums should be spent on institutions calculated to benefit the whole service and in furtherance of *some general scheme of organisation*

There is one more difficulty which Dr Toogood seems to consider as final in the matter of the scheme I have drafted This is the distance which patients would have to be carried to the central *institutions* *But the extreme distance of any* of the unions from the central institution to which they are affiliated would only be 15 miles by road or 30 by train Surely Dr Toogood would not think this too far' The removal of a patient would of course, be subject to the certificate of the medical officer of the district workhouse (My scheme provides for the nursing of acute cases at their own unions) Country people think nothing of such distances and patients in a critical condition often travel up to general hospitals from far longer distances

Finally, I would say that one leading feature in my scheme is the establishment of one standard for the nursing of every case which enters the sick wards of a workhouse small or large in town or in country The pioneer work of the Workhouse Infirmary Nursing Association was directed to this end, and it only ceased to train nurses when while feeling that the system should be self supporting it decided that the supply of nurses had become too large a question to be dealt with by a voluntary association So far from "making spies and rebels of' its nurses it was almost invariably the rule that when it *support and encouragement were withdrawn (for any reason)* from its nurses that they found it impossible to stay any longer in the workhouse infirmary The desire which is constantly expressed that the Association would restart its *work of training nurses at once disproves any such uncalled* for charge as that which Dr Toogood makes and which he should withdraw —I am Sirs yours faithfully

Fellows road N W Sept 22nd 1901 J R HUMPHREYS

NORTH INDIA SCHOOL OF MEDICINE FOR CHRISTIAN WOMEN

To the Editors of THE LANCET

SIRS —Seven years ago inquiries were made by the women medical missionaries of the Punjab as to the possibility of obtaining the assistance of native Christian girls of good family as fully qualified house surgeons anæsthetists and nurses The result of these inquiries showed that if a school was provided which gave full and thorough medical training for women only it would meet with every possible encouragement, therefore in the following year, the above hospital and school were opened in Ludhiana

This hospital is unique in that it is the only medical school for women in India where the students are taught by women where they can study apart from the Hindu and Mahomedan male students and where they can receive their clinical teaching in a hospital for women and children That it has proved a success is evident from the following facts —(1 [illegible] Government as a medical school, (2 [illegible] sent students for training [illegible] five compounders eight nurses and six midwives have already successfully completed their course of study at the school and are now engaged in medical mission work in connexion with seven different societies (4) that 16 medical students, 16 nurses and two compounders are still in training, and (5) that many applications are received for trained workers and the reports received about most of the trained students are very encouraging both as to the success of their medical work and the interest which they show in the spiritual welfare of their patients Besides alleviating bodily suffering it may reasonably be hoped that the influence of the Christian medical students will aid the progress of Christianity in India

As the medical school is not yet affiliated to any university the students are at present only eligible for the Government examination for hospital assistants and not for any university [illegible] degree [illegible] would [illegible] ing their [illegible] and who would be allowed by their parents to go to it they could study at a women's college The University of Lahore is willing to affiliate the school as soon as three more members are added to the teaching staff and when good laboratories for anatomy chemistry, physiology, and bacteriology &c. have been provided The 100 hospital beds required to ensure sufficient clinical teaching are already established In order to build and furnish these laboratories and an operating theatre and to supply the outfit and the passages of the extra members of the staff, a sum of £5000 is needed If this money can be raised and the improvements carried out the students will then be eligible for any university degree and will become on passing the necessary examinations, members of the recognised Indian medical profession. To attain this object the committee (consisting of the Lady Kinnaird, the Lady Macnaghten, Miss Maynard, Mrs. Percy Flemming, M.D. Lond., Miss E. Brown, M.D. Brux., the Bishop of Calcutta, Sir Charles Bernard, Dr. W. J. Smyly, Dr. E. Sargood Fry, and Mr. A. Pearce Gould) make an urgent appeal for funds. Subscriptions will be gratefully received by the Lady Macnaghten, 198, Queen's-gate, London, S.W., and Miss E. Brown, M.D. Brux., 120, St. James's-road, West Croydon, Surrey, or may be sent to the "North India School of Medicine Fund," Union Bank (Tottenham Court-road Branch).

We are, Sirs, yours faithfully,
F. A MACNAGHTEN, } Honorary
E. BROWN, } Secretaries.

"THE CHEAP PISTOL."

To the Editors of THE LANCET.

SIRS,—Your sound common-sense annotation upon the indiscriminate manner in which cheap firearms are sold everywhere and the announced determination of the American Government to deal with the class of people from whom these assassins emerge urge me humbly to suggest that our Government should join with the Americans (and I hope all the European and peace-loving Governments) in passing a universal law that every person of every nation should not be allowed to carry any description of arm or weapon that could be used to endanger the life of any other person or animal without a permit or licence; and, further, that no person or persons should be allowed to supply or furnish to anyone else such arms or weapons unless the intended buyer was duly licensed or officially authorised. In addition, manufacturers and salespeople should be licensed to follow their avocation, all licences to be renewed annually and every change of address duly given to the proper authorities directly the change is made.

I am, Sirs, yours faithfully,
Ebury-street, S.W., Sept. 23rd, 1901. D. T. BOSTEL, sen.

"STOCKS AND CROSSMAN *v.* WATSON."

To the Editors of THE LANCET.

SIRS,—THE LANCET of July 13th, containing your leading article on the above case, has just reached me. I think that from a medico-legal point of view, as well as from a purely surgical one, it is of great interest. Mr. H. H. Clutton and Mr. Victor Horsley were of opinion "that the injury to the shoulder might have predisposed it to dislocation and that an injury subsequent to the bicycle accident ...... might have produced it." Is it not possible that this is more common than is generally supposed? When the ligaments of a joint are badly torn it should not be a very difficult matter to produce luxation subsequently, especially in the shoulder-joint, with the shallow glenoid cavity and the large head of the humerus. It has happened to me to have had under my care two cases which illustrate what I mean, though they were not in the shoulder-joint.

1. About 20 years ago I was called to see a woman, aged 30 years or thereabouts, who had fallen and injured her wrist. There was certainly no dislocation—one could scarcely be mistaken in such a case—but the joint appeared to have been severely strained. I applied a light splint and ordered a cooling lotion. A day or two afterwards I called and found that the patient had removed the splint and had been sweeping. I declined to continue in charge of the case, as my instructions were disregarded, but meeting her some time afterwards I found that there was a partial dislocation; it was easily replaced, but readily slipped out again. I wish I could remember the details more accurately, but I have no notes of it, and 20 years is a long time.

2. In November, 1899, the Sikh sergeant in command of the detachment of military police stationed at our mines was knocked down by a tramcar loaded with firewood. He had his little son, aged about two years, in his arms at the time, and in endeavouring to save him from injury, in which he was fortunately successful, paid less regard to himself. The only injury of consequence was to the knee-joint. I saw him within half an hour of the accident and there was certainly then (or while he was under my care) no dislocation. Severe inflammation followed, with a good deal of pain. He got very frightened about himself (he is a very nervous man) and ordered a boat to take him to the station at the mouth of the river, the district headquarters. He walked to the boat, a distance of about 100 yards, though I had ordered him to be carried. When at Kuantan his nervousness only increased, and a steamer being at the dock bound for Singapore he went (ran, I was told) to it and tried to get on board. He had to be brought back by force. About two months ago I examined him with the Residency surgeon of the State. There was an undoubted lateral displacement of the bones of the leg. The articular surface of the external condyle of the femur could be distinctly felt and there was a marked curvature of the whole limb.

I do not suppose my experience is at all peculiar; doubtless many others could supply histories of similar cases.

I am, Sirs, yours faithfully,
J. W. ROLPH,
Medical officer, Pahang Corporation, Limited.
The Mines, Sungei Lembing, Kuantan, Pahang, Malay Peninsula, August 20th, 1901.

"A PECULIAR METHOD OF SUICIDE."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Sept. 14th, p. 744, a description is given by Mr. C. A. J. Wright of Leytonstone of a method of committing suicide, and you remark that you should think it unprecedented. If, however, you will turn to THE LANCET of June 22nd, 1889, p. 1242, you will find a description of a suicide on somewhat similar lines under the care of Mr. Hulke at the Middlesex Hospital, and another by myself in THE LANCET of Oct. 19th, 1889, p. 791.

I am, Sirs, yours faithfully,
Maryport, Sept. 23rd, 1901. JAMES LITTLE.

"THE ELECTROLYTIC TRANSMISSION OF SULPHUR."

To the Editors of THE LANCET.

SIRS,—My letter of August 24th seems to have given Dr. F. W. Smith the impression that I wished to belittle his valuable observations on the electrolytic deposit of sulphur from the Harrogate waters. Far be it from me to detract in any way from this new application of an old principle. Dr. Smith is in the van of progressive medicine, and I perfectly recognise the value of the investigations which he has made. But at the same time I must demur to his use of the word "discovery" in connexion with this subject. Doubtless Dr. Smith has been the first to apply the principle of cataphoresis in hydrotherapy, and I hasten to congratulate him upon the impetus which his investigations will certainly give to hydrotherapy all over the world. The principle of cataphoresis, however, which is the whole soul of the matter, has long been known. In 1858 Theodore Clemens, as a result of clinical experiments, claimed beneficial results from the electrolytic transmission of iodin through the skin. In 1859 B. W. Richardson made exhaustive experiments in the production of local anæsthesia by the cataphoretic introduction of a mixture of aconite and chloroform, by means of which he was able to perform many operations painlessly. But the profession at large was chary of adopting a method which was theoretically sound but which to the hyper-sensitive palate of prejudice might smack somewhat of charlatanism. The industrial arts, however, as Jacoby remarks, quickly recognised the value of the method. For instance, the tanning of hides by electricity became quite general when it was learned that by means of the usual tanning solution and an electric current a hide could be tanned in four days, while by ordinary methods it would require from 10 to 12 months to complete the process.

There are certainly factors which militate against the adoption of this method as a means of general medication, not the least of which is the fact that comparatively small quantities of a medicinal agent can be transmitted and these become rapidly eliminated by the emunctories. But as a method of local medication the method is more promising, especially if Morton's plan of rendering the part to which the application is to be made as far as possible anæmic beforehand be employed.

I am, Sirs, yours faithfully,
CHARLES J. NEPEAN LONGRIDGE.
St. George's Hospital, S.W., Sept. 25th, 1901.

"THE HABITUAL INEBRIATES ACTS"

To the Editors of THE LANCET

SIRS,—As one who has worked for many years among the class from which the habitual inebriate is largely drawn I was pleased to read the very pertinent remarks of Dr L A Parry on this subject in THE LANCET of Sept 21st, p 786

It seems to me that either the scheme of private or local reformatories must altogether fail and the entire class of inebriates become the special care of the State or else the managers of the former institutions must make up their minds to a radical alteration of their present "rose water" rules and procedure Lady Henry Somerset refers to "dangerous" cases being sent to her Now, with the greatest respect for this lady's opinions, I prefer to take the view which I believe is unanimously held by prison officials—i e, that inebriates are far more undisciplined than felons In other words the inebriate (continuing like Dr Parry, to speak mainly of the female variety) usually *is* "dangerous" in the sense of being a brutalised half unsexed virago, who on the slightest thwarting of her individual desires will indifferently assault, as likely as not with the nearest lethal weapon whosoever may have incurred her displeasure What does she care for the flowers and the [illegible] "sweetness and [illegible]ly barter all for [illegible] she sighs for the fighting the squalor, the obscenity of her filthy lodging-house or slum What if she did find herself at short intervals in gaol? The sentence was not as many weeks as she is now serving years, and at the worst it served to recruit her powers for fresh debauchery or the propagation of a race of degenerates I have been told on what I believe to be good authority that many of the women whom Lady Henry Somerset doubtless classifies as "dangerous" have shammed insanity or have committed assaults or damage with the single idea of escaping from the reformatory Could anything be more farcical? The climax of absurdity is reached by one institution, which I forbear to specify which insists on the *sexual purity* of its candidates for admission as if an inebriate were not the one woman of all others whose loss of self respect has long robbed her of such an attribute

I am, Sirs, yours faithfully,

A. W P

Sept. 23rd 1901

SOME MEDICAL ASPECTS OF THE PAN-AMERICAN EXPOSITION AT BUFFALO

(FROM OUR SPECIAL CORRESPONDENT)

IN former communications to THE LANCET[1] respecting the model brigade field hospital exhibited at the Pan American Exposition the most important features were described With an account of the United States army ambulance a description of this exhibit will be complete

The United States army ambulance of the latest pattern is intended to be drawn when in the field, by four mules and has a total weight unloaded of slightly less than 1400 pounds The inside width of the wagon box is 82 inches its length over all is 106 inches and the length of the litter space is 91 inches There are hinged seats capable of accommodating 12 patients when seated these seats swinging back out of the way against the sides of the ambulance when the latter is used for recumbent patients A stout post permanently fastened in position rises from the centre of the litter space in front to the roof of the ambulance This post is provided with leather covered metallic hooks about half way up which receive the inner handles of the two litters forming the upper tier A similar post at the rear of the ambulance provides support for the rear of the same litter shafts the post swinging up out of the way and being strapped to the roof when not in use The two litters of the upper tier are supported on their external aspect by having the litter handles of the outer poles inserted in loops of leather straps suspended from the ambulance roof The lower tier of litters is loaded directly on the ambulance floor between the supporting posts and the packed seats of the ambulance The latter thus has accommodation for four recumbent patients or for two recumbent patients and six seated The fact that both recumbent and seated patients can be carried at the same time is of great practical importance The ambulance is furnished with small hammocks hung along the sides similar to those used in sleeping cars, for the carriage of the patients effects The roof is of light wood, covered with "pantasote" a new material which is waterproof fireproof durable as leather and not readily torn by brush or overhanging branches The wagon wheels have broad tyres and iron axles There are accessory springs so that the vehicle rides as easily with three or four occupants as when loaded with eight or ten Water is carried in metallic receptacles underneath the floor of the ambulance and behind the rear axle It is readily accessible yet when the tail gate of the wagon is dropped as in loading patients, the containers are perfectly protected from injury The box underneath the driver's seat is intended to contain three boxes of the same size so as to be interchangeable one containing dressings another stimulants, and the third condensed foods The front wheels of the ambulance "cut under" so that the vehicle can turn in its own length This ambulance is a result of a careful study of the transportation of wounded by a board of medical officers from experience gained during the recent Spanish American war As showing its superiority over other patterns it is only necessary to say that it has lately been adopted in the Canadian militia and that samples have already been ordered for trial by the Governments of Great Britain, France Spain and Chili

That the equipment of army field hospitals of the United States is in a high degree excellent is freely admitted by army surgeons of other nations The commendations passed upon these hospitals in China were very high and when the fact is taken into consideration that the ones in use there were not nearly so well equipped as they are at present it will be easily understood that the arrangements of the United States Army Medical Department are worthy of close attention by similar departments of other armies

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT)

The New General Hospital Calcutta —Bombay City and the Recent Census —Dr Nield Cook's Deputy —The Indian Medical Service —Vaccination and Smallpox in Bengal —The Standard of a Well filtered Water —Regimental Cooks

AFTER considerable delay the new block of the Presidency General Hospital was formally opened by the Lieutenant Governor on August 31st It is a plain building outside but replete with every convenience within Great care has evidently been bestowed upon its construction which is up to date in every particular There are three storeys identical in their construction and arrangement and each storey has two large open wards with service rooms and offices adjacent while between the wards in the centre of the building are groups of rooms for private patients, sisters, resident officers &c Altogether it will provide accommodation for about 160 patients There is an excellent verandah for each storey and the roof has been arranged to form a magnificent promenade The operation room over the portico facing the north is particularly good and has been fitted up on the latest scientific principles Electric fans lights lift and water pumps constitute the excellent electrical installation The kitchen and the [illegible] quarters are in separate detached buildings One oversight has certainly been made but there is still time to remedy it A large dirty [illegible] is situated close to the front of the building and within [illegible] the ground Surely this should be filled up as it is of no use but may be a positive danger to the [illegible]

The returns of plague mortality from various places continue to show large [illegible] Mysore [illegible] Bombay city and Karachi the disease is active At Bombay the Government [illegible] published [illegible] the census He calculates [illegible] population [illegible] the census [illegible] 115 000 The mortality of Bombay in the recent [illegible] census being taken during the height of the [illegible] estimated that 30 000 resident [illegible] that perhaps as many [illegible] of the city [illegible] afield The most densely peopled part of the city [illegible] 598 persons to the [illegible] Calcutta It has been discovered in the census that there are no less than 53 dialects spoken in the city, and that only about a fourth of its total population were born in it. Two houses were found to contain 691 and 663 inmates respectively and the most crowded room had 54 occupants!

---

[1] THE LANCET Sept 14th (p 749) and 21st (p 809) 1901

During the absence on privilege leave of Mr. J. Nield Cook the Corporation of Calcutta have asked for the services of Dr. T. F. Pearse, one of the plague officers. There being little plague in Calcutta at the present time work in this department must be reduced to a minimum. Dr. Pearse should be well qualified for the post as he holds high diplomas in medicine, surgery, and public health.

It is understood that the Secretary of State for India has sanctioned the strengthening of the Indian Medical Service by the addition of 26 officers and that the Government of India will shortly announce their intentions as to recruitment.

A resolution of the Government on vaccination in Bengal has just been issued. Small-pox was very rife during the past year and in some of the districts only a small proportion of the population has been protected by vaccination. The Lieutenant-Governor refers particularly to the insufficient protection afforded by the arrangements in Calcutta, but finds evidence of real progress in other towns where vaccination is compulsory. The difficulty in Calcutta is the large immigrant population. In the outlying districts the proportion of protected persons is very small. The total number of deaths from small-pox in Bengal was 25,302, against 14,514 in the preceding year. Out of 476 persons admitted into the Campbell Hospital in Calcutta only 124 had been vaccinated. It must be admitted that the obstacles to extensive vaccination are enormous.

Mr. Hankin in his report to the Government of the North-West Provinces lays it down that a public water-supply may be considered "well filtered" if it contains less than 100 microbes per cubic centimetre. This is a somewhat lower standard than that of some authorities, but according to it the municipal water-supplies in the North-West Provinces are shown to have been "well filtered."

The experimental scheme under which British troops in India are to do their own cooking is a matter of the highest importance. When soldiers are in the plains during the hot weather there may be difficulties, but during the cool season and when in the hills there is no reason why the cook-boy should not be abolished. The experiment was tried a few years ago with the Gordon Highlanders and for months together not a single case of enteric fever occurred. I understand that men trained in England are to be eventually attached to regiments in India. It is not sufficiently recognised that though the native can cook he is a very dangerous cook. He will keep dirty pots and pans, foul water, and fouler dishcloths, and he has not the remotest idea of sanitary precautions. The cooking must, of course, be well done or there will be other troubles. It behoves the authorities, therefore, to supply the trained men without delay or the substitution of the soldier-cook for the native one may in the meantime prove disastrous to the proposed change.

Sept. 7th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Houses and Health.

IN the present day we are met with many schemes for the development of ideal modes of dealing with the various influences which retard our physical and moral progress. One or two enthusiasts full of abstract notions of virtue and philanthropy combine with some followers to form an association, an attractive title is assumed, and the propaganda go forth. In many instances the objects set out are laudable and praiseworthy; in the majority there is an unbiased desire to benefit the human race; but there is generally a vast difference exhibited between what is theoretically advanced and what is practically possible. An instance of this kind is displayed in the Garden City Association which has recently held its conference in Birmingham. The present conditions of life in cities were pointed out as likely to reach a point in which the race would become degenerate, when we should be no longer able to hold our own. The advantages of a garden city were explained to be increased light and space, cheapness of land, readiness of market, facilities in getting to and from work, and all the attractions of a country life. We are all aware that the unfavourable conditions of life in crowded cities must be detrimental to health, and we view the slums of such localities with abhorrence and dismay. But the plan of reformation is not so easy as the promoters of the Garden City Association would wish. The minor industries of agriculture and gardening may possibly be fostered by such benevolent advocates; but the greater manufactories of towns must be located for the present, we fear, in confined areas. Though in some instances the managers of large industries have taken their works outside the city and have thus brought comfort to their operatives, it is somewhat utopian to expect that this course can be pursued on a scale sufficient to meet the demands of the ever-increasing growth of the population. The sacrifice of commercial interests entailed is too heavy.

Epidemic of Scarlet Fever.

The Health Committee have to face an increase in the cases of scarlet fever. At this season the type of cases is mild and the mortality in proportion to the number has been low. Still, the increase in the numbers admitted into the infectious hospitals is great enough to give apprehensions as to the accommodation at the disposal of the committee. Thus last week there were 471 patients in the scarlet fever hospital, as compared with 324 in the corresponding week of last year, and the record shows an earlier time of the increase for the season. Arrangements are being made to provide extra room for any additions, and there is every reason to believe that due preparations will meet any emergency. Cases of typhoid fever form a large item in the work of the Health Committee. 28 cases were reported last week, with 60 cases already in the hospital. A large number of these cases are also treated at the General Hospital and the Queen's Hospital, where it is considered by some unwise to admit such patients. Certainly disasters at times occur among those who attend to them, in spite of all precautions and care.

Poisons in Medicine Bottles.

A lamentable instance of death lately occurred from the want of some distinctive mark between bottles containing poison and those containing medicine. A man, aged 39 years, complained of having a cold and remained in bed. The medical attendant prescribed two draughts in small bottles, one to be taken at night and one in the morning; a small bottle of carbolic acid was also bought at a dispensing chemist's for inhaling. It was supplied in a bottle almost identical with the others, but labeled "Poison" in red. The bottles were placed on a tray by the servant and were carried upstairs. The night draught was given as directed. In the morning the wife of the patient administered, as she thought, the second draught, but immediately it was swallowed the patient became aware that the wrong bottle had been emptied and he died in 20 minutes. Many plans have been proposed for avoiding such mistakes. The most feasible would be, it seems to me, that all poisons should be sold in screw-stoppered bottles, which would thereby attract attention to the contents, though this would not be infallible unless other medicine bottles were universally precluded from having this form of stopper. Nothing, as a matter of fact, can supply the want of thought and care which should be associated with the function of nursing the sick.

Vaccination Exemption Certificates.

At a meeting of the West Bromwich Board of Guardians attention was recently drawn to the excessive fees which were charged for vaccination exemption certificates. It was stated that in many instances not only did the fathers lose a day's work in attending before the justices but were charged 3*s.* or 5*s.* for the certificates. The chairman pointed out that the guardians had no jurisdiction in the matter and ruled any discussion on the subject out of order. A notice to move a resolution another time was carried.

Sept. 24th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Blind of Manchester and Salford.

HENSHAW'S Blind Asylum has long been known beyond the limits of Manchester and Salford as an institution that has deserved well of the community, but for some time it has had its critics, which, perhaps, is not to be wondered at, for the old ways of an institution tend to become stereotyped while those outside it look for progress Moreover, it cannot cover the whole ground There are in the two towns which, *pace* Salford, may for the nonce be called Manchester, some 500 poor blind people who, with a few exceptions, receive no help from the charity The first article of its regulations is as follows "To afford an asylum for the impotent and aged blind, and to maintain and afford such instruction to the indigent blind of both sexes capable of employment as will enable them to provide, either wholly or in part, for their own subsistence, and to promote the employment of, or to employ, blind persons." This comprehensive scheme, however, is not carried out, partly, perhaps, because it is so large and partly from lack of funds, and the central institution has become the chief care of the managers The asylum itself gives a good elementary education and boards 90 blind children, it trains some 50 men to trades, and it houses and feeds 50 old men and women To make it possible for much more than this to be done there must be more and larger subscriptions It is said that "the public gives its support spasmodically," and that the strictest economy has to be exercised, so that "with the present income it would be hazardous to undertake additional responsibilities" Even now, however, something is done for the blind outside the walls of the asylum There are workshops in Deansgate with a shop for the sale of work at which 50 blind persons earn small wages They were built at a cost of £11,000 which was provided by a comparatively small number of persons, and they are carried on unfortunately at an annual loss to the asylum of £700 Pensions also are given "to 112 persons at a cost of £800 a year, they have occasionally made loans or gifts of money to start the blind in business and they have paid the fees of old pupils at the asylum who have proceeded to colleges" but the institution has failed in the 'after care" of those whom it has trained and sent out into the world, and without this the majority are apt to drift into beggary and street organ playing There is room, therefore, for a society to do the work which the asylum cannot do, to help the outsider, and one indeed, has been at work for about 18 months mainly through the initiative of a lady, Miss Isabel M Heywood who for some years has been accustomed to read to the blind workers in the Deansgate workshops during the dinner hour She wrote, with the help of a few friends, to the clergy and ministers and other workers among the poor, and by their aid obtained a pretty correct register of the poor blind The Manchester and Salford Blind Aid Society was formed, with Sir William Houldsworth, M P, as president. One of the first steps taken was to appoint two blind visitors to the blind, who will talk to them more freely of their circumstances and needs than to 'sighted" people The society has also a sick and benefit branch, a home of rest at St Anne's on the Sea a home for blind women in Salford, a visiting branch with about 50 visitors in all parts of the district, and a Braille library They have also two or three rooms in the old Eye Hospital where the blind go to read their Braille or Moon books, and where they have occasionally tea and music and once a week a religious service Sometimes there are 60 or 70 at the "socials,' and there was a blind picnic recently at which the Bishop of Manchester spoke, which was attended by 350 persons. The object of the society is as far as possible to help the blind to help themselves and to be self-supporting There are among them organists, pianoforte players and tuners, wood choppers knitters, Braille writers tea agents, &c., and as far as possible help is given in the way of finding work and situations Both the old asylum at Old Trafford and the Blind Aid Society are worthy of help, though the former has not escaped censure Archdeacon Wilson seems to consider it a long way from being in the front line of the "centres of blind instruction" and that no real advance will be made without "a strong and entirely independent commission, including some experts in the training and care of the adult blind, with power to report on the whole scope and results of their work and its cost and to make recommendations" If such a commission will bring new life to this old charity it should be appointed without delay The critics who only criticise and give no help in setting things right are of no great value

Prison v Workhouse

Much discussion is going on as to the treatment of pauper children, and there seems to be a strong feeling in favour of their being saved from the contamination of the workhouse *Apropos* of the Youthful Offenders Act, relating to children whom the magistrates remanded to the workhouse pending their trial, Mr Scott, master of the Carlisle Workhouse, said that it would be much better for them to be remanded to the prison than to the workhouse The clerk to the guardians said that a slur was cast on them by being in prison, even though they might be proved to be innocent, but the master repeated that they had better be sent to gaol as in the workhouse "they were bound to associate with some inmates regular old criminals," and would be less likely to receive contamination in gaol. This is a strong argument in favour of cottage homes or of boarding out

More Males than Females

The census returns for the Northwich Urban District have brought out the fact that the number of the male population was 9015, while that of the females was 8596 This is accounted for "by lack of opportunities for female labour" The same preponderance of males exists also at Crewe and for similar reasons—a state of things quite opposed to that of the country generally, where as a rule the female population is in excess

Parks and Recreation Grounds

Though the Manchester parks do not force themselves on the attention of the casual visitor, who may come and go without being aware of their existence, a good deal has been done, especially of late years, towards providing breathing spaces, or lungs, as they are called, for the ever increasing population Indeed, it is only in comparatively recent days that the corporation have risen to the idea that they had any duties or responsibilities in the matter and many valuable opportunities of acquiring open spaces have been lost However, since 1846 the capital sum spent on this object has been £445 127 The area of the various sites acquired, some large some small, some by purchase and others by private beneficence is over 411 acres and with the cemeteries it amounts to 632 acres This is exclusive of Heaton Park which the City Council recently decided to purchase Its area together with that of some adjacent land to be included in the purchase, will not be far short of 700 acres

Sept 24th

WALES AND WESTERN COUNTIES

(FROM OUR OWN CORRESPONDENTS)

The Gothenburg System at Barry

THE progressive town of Barry, the population of which has increased from 165 in 1881 to 27,028 in 1901 is quite keeping up its reputation by providing the first licensed house in South Wales to be conducted on the lines of the Gothenburg system On Sept 19th the Barry licensing justices granted a licence to the representative of a limited liability company who are the owners of a recently erected hotel The articles of association of the company provide that the shareholders shall not receive a dividend of more than 6 per cent The remaining profits are to be divided among certain objects in the county of Glamorgan to be elected by the Lord Lieutenant In the event of the sale of the licence the whole of the profits resulting from such sale are to be divided as the Lord Lieutenant may direct. Contributions may be made to the Cardiff Infirmary and to the Barry or other nursing associations and there may also be provided by the company or contributions may be made towards the provision of a reading room an institute, a public library a gymnasium, a public hall, or swimming baths in any part of Glamorgan If this venture is successful there is no doubt that it will be followed by others in the colliery districts where the licensing justices grant fresh licences every year

Poor law Conferences

Two conferences of Welsh Poor law unions representatives were held on Sept 18th Delegates from the unions of North Wales met at Rhyl and from the unions of South Wales at Langland Bay The Rhyl meeting was addressed by Dr J Lloyd Roberts upon the Housing of the Poor as it affected Pauperism Dr Roberts urged that county councils should be asked to include classes relating to domestic matters in their technical instruction schemes At Langland Bay the question of out-door relief was discussed when it was suggested that a series of questions should be sent to applicants for relief as to their past careers and opportunities for thrift, and that the industrious and unfortunate should be relieved in preference to the idle and thriftless. Sir John Llewellyn stated that in Swansea a man who had been a member of a friendly society was always looked upon as a worthy applicant Miss C. M. Williams read a paper upon Some Aspects of Hospital Management, in which she spoke strongly of the necessity for employing paid labour and of the unsatisfactory results attending the employment of patients as nurses, especially upon the male side. She considered that the difficulty which many of the smaller unions found in obtaining and keeping nurses was due to the absence of any organised system of promotion and to the objection which many nurses had to being regarded as Poor-law officers.

Conference on Tuberculosis at Cardiff.

The Mayor of Cardiff has issued invitations to a public conference to be held at Cardiff on Oct. 3rd to consider the propriety of establishing a South Wales and Monmouthshire Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis. The response to the invitation by sanitary authorities and others has been very large and it is anticipated that the conference will be a successful one. At a meeting of the Swansea Corporation held on Sept. 18th a report from the Sanitary Committee was accepted in which the opinion was expressed that it was very desirable that a sanatorium for the treatment of patients suffering from phthisis should be established in South Wales.

Accident Hospital for Ebbw Vale.

A small accident hospital for the workmen employed at the Ebbw Vale collieries was formally opened on Sept. 21st by Mrs. Gordon-Canning, one of the ground landowners of the colliery. There is accommodation in the hospital for 10 patients in three wards. The kitchens and wards are on the first floor, and on the ground floor are the matron's rooms, a convalescent room, a receiving room, and an operating theatre, this last having smooth cement walls and a floor of terrazzo. The building and furnishing cost £3050. The greater portion of this sum was contributed from the workmen's medical fund which has about 7000 members. The workmen have consented to the deduction of a halfpenny in the pound from their wages in support of the institution.

Isolation Hospital at Ogmore.

The Ogmore and Garw Urban District Council have decided to erect an isolation hospital with accommodation for 12 patients upon half an acre of land situated near Brynmenyn at an estimated cost of £6000. The district is growing rapidly owing to the extensive mining operations. The population, which in 1881 was 6893 and in 1891 was 13,800, had increased at the last census to 19,912.

Hospital Saturday at Swindon.

As a result of the recent Hospital Saturday collections the sum of £130 has been handed over to the Swindon Victoria Hospital. Since 1885 sums amounting to £1373 have been forwarded to the hospital authorities, the average for the past five years being £111.

Vaccination Grant.

Mr. J. Dibble Staple, M.R.C.S. Eng., L.S.A., public vaccinator for the Ashley district of the Bristol union, has for the second consecutive time been awarded a Local Government Board grant for successful vaccination.

Sept. 23rd.

SCOTLAND.

(From our own Correspondents.)

New Parish Hospital, Glasgow.

The memorial stone of the new general hospital which is being erected at Stobhill by the Glasgow Parish Council was laid on Sept. 16th by the Right Honourable Lord Balfour of Burleigh, K.T., Secretary for Scotland. The hospital covers 53 acres, will provide accommodation for 1500 patients and 150 nurses and other members of the staff, and its estimated cost is £200,000 It stands on an admirable site, 350 feet above the sea-level, and commands a fine view of the open country. The buildings are to be constructed according to the most modern plans and the equipment is to be in every sense complete. The institution is intended as a general hospital and infirmary for aged and infirm persons, and also for phthisical cases. On a separate part of the ground provision is being made for the reception of 400 children, the greater number of whom are ultimately to be boarded out—that is, as soon as opportunities for doing this can be secured. The parish council has, in addition, undertaken to erect two other hospitals, one at the west end and the other at the east end of the city; these are to be fitted up entirely for acute curable cases. In this way it is intended, by separate classification, to surmount some of the difficulties and objections which at present exist in the treatment of those who become chargeable to the public rates. The new hospitals will allow the old buildings to be used solely for those among the applicants for indoor relief who are fitted to perform a greater or less amount of manual labour. Lord Balfour spoke in appreciative terms of the policy of the Glasgow Parish Council and stated that it had the most cordial approval of the Local Government Board for Scotland. He considered that the administration of the Poor-law, though not absolutely beyond reproach, was such as to secure for the majority of those who deserved it the greatest possible consideration. Speeches were also delivered by the Lord Provost of Glasgow and by Mr. Brand, the chairman of the council. The latter argued that power should be given to the parish councils to deal with incorrigible drunkards. Numbers of these were continually entering and leaving the poorhouse, and if they could only be detained a serious, and he believed a successful, attempt at their reform could be made.

British Association at Glasgow.

The sectional meetings of the British Association were brought to a close on Sept. 19th. Several of the papers read during the week were of unusual interest. Major Ronald Ross, in dealing with the subject of malaria, described the part played by the mosquito in the dissemination of the disease and expressed the opinion that by the extinction of the mosquito every town in the tropics in the course of a few years would be freed from the malarial poison. All that was necessary was to clear away every drop of stagnant water through the town by a means of a gang of men maintained for the purpose by the local municipality. Major Ross described the experiments now being carried on in Sierra Leone by the Liverpool School of Tropical Medicine assisted with a sum of £2000 subscribed by a west of Scotland gentleman. The experiments have been in progress for two or three months and have already produced an obvious reduction in the number of mosquitoes. In the Zoological Section also Dr. Rankin of Glasgow University announced that arrangements had been made at the Millport Marine Biological Station for the erection of a research laboratory and also of a private boarding-house. The site for the new buildings has been promised by the Marquis of Bute, and a gentleman who prefers to remain anonymous has given £3000 towards their erection. In the same section an exhibit which attracted much interest was that of three hybrid zebras which were shown by Professor Cossar Ewart. The animals, which were very graceful and were much admired, were seen quietly grazing in the University quadrangle. One of them was described as reproducing "fairly accurately the colouration of the primeval common ancestor of the horse and the zebra." One use to which it is suggested these animals may be put is in connexion with mountain batteries. A discussion in the Economical Section on the Housing Problem excited much interest. It was introduced by Professor Smart, LL.D., and in the course of it the Lord Provost offered an eloquent defence of the policy of the City Improvement Trust. The Association next year is to meet at Belfast.

Bequests to Glasgow Hospitals.

The trustees under the will of the late Mrs. James Rodger, Glasgow, have intimated the following legacies: to the Glasgow Royal Infirmary, £3000; to the Western Infirmary, £1500; to the Victoria Infirmary, £1000; and to Quarrier's Orphan Homes, £1500. A further sum of £1000 is distributed among the special hospitals and other charitable associations. It should be mentioned that Mrs. Rodger in 1891 divided £10,000 among the Glasgow hospitals and benevolent societies and that in 1893 she made a similar distribution of £3000.—The late Mr. James McWilliam, Glasgow, has left a sum of £500 each to the Royal Infirmary, the Western Infirmary, and the Victoria Infirmary.

Glasgow University.

Mr. Alex. Galt, D.Sc., who was for several years official assistant to Lord Kelvin in the University, has been selected by Lord Balfour of Burleigh for appointment to the technological department in the Edinburgh Museum of Science and Art. This is a new appointment having for its object the development of science and art in their relations to technical education.

Sept. 24th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Typhoid Fever at the Richmond Asylum.

AT the meeting of the Committee of Management of the Richmond District Lunatic Asylum held on Sept. 19th the medical officer (Mr. Conolly Norman) submitted a special report on the occurrence of typhoid fever in the asylum last autumn and its recurrence recently. Last year the infection broke out in the month of August and attacked only the female department, the nurses being the first to suffer and subsequently the patients. There were 54 cases altogether and seven deaths. The observations of the medical staff led them to the conclusion that the method of inoculation with anti-typhoid vaccine, which was energetically carried out, prevented a much larger spread of the disease. In the month of August of the present year typhoid fever again appeared in the female asylum. One nurse and four patients were attacked. Last year Sir Charles Cameron reported on the matter and drew attention to some defects in the sanitary arrangements which were at once set right. The medical superintendent states his own opinion that the occurrence of typhoid fever was due to the condition of the underground drain which runs partly under the main female house and which has long ago been looked upon as a source of danger to the institution. The committee unanimously resolved to refer the matter to the city engineer.

The Royal Commission on University Education.

The Royal Commission on University Education had their first sitting in the Royal University Buildings, Earlsfort-terrace, Dublin, on Sept. 19th, the Right Hon. Lord Robertson, the chairman presiding. To the surprise of everyone when the press representatives appeared they were informed that the Commissioners had decided to conduct the proceedings in private and that they would not be admitted at any time, but that the secretary would see that official reports were published. This decision, though it may follow the precedents of other Royal Commissions has given the greatest offence and is really an error in tactics. When a Commission about the mode of appointment and *personnel* of which there has already been so much discussion decides that its proceedings shall be held *in camerâ* it is not to be wondered at that from all the Irish newspaper press, representing every shade of thought and political opinion on this most difficult subject, there is for once a unanimous protest. The evidence of the secretaries of the University, Bishop O'Dwyer of Limerick, the President of Queen's College, Belfast, and the President of University College, Dublin, has been taken.

Hospital Saturday in Carrickfergus.

The Saturday collection for the Royal Victoria Hospital, Belfast, was taken up in Carrickfergus (the old county town of Antrim) on Sept. 21st, when upwards of £28 was the result, an increase of £6 over the total of the previous year.

The Forster Green Hospital, Belfast.

At a meeting of the General Committee and friends of the Forster Green Hospital for Consumption and Diseases of the Chest, held at that institution on Sept. 21st, the secretary reported that on Jan. 1st 23 patients were in hospital. 105 have since been admitted, making a total of 128 cases treated during the current year. The average number of patients in hospital at one time has risen from 24 in 1900 to 29 this year. A total of 34 beds will by certain rearrangements be soon available, a supply very inadequate to cope with the enormous number of persons affected in this district with tuberculous disease. The public are specially appealed to for help, as between the present time and the end of the year £1162 are needed without going into debt. The open-air treatment is being thoroughly carried out at this hospital and ample confirmation (medical and lay) was given at the meeting as to the success of this modern treatment.

The Outbreak of Typhoid Fever in Belfast.

There is practically no change yet in the outbreak of typhoid fever, and at present, in addition to a very large number of cases of that disease there are 23 cases of diphtheria, an altogether unprecedented epidemic of that zymotic. The weather at present is very wet and the temperature keeps high, a sort of English "monsoon," and with just the conditions suitable for bacterial growth. At the last meeting of the Public Health Committee attention was drawn to the practice which some medical men, it is reported, have of holding over notifications of cases of infectious disease till they have several to notify at once. It is probable that the medical men would reply that until they are quite sure it is wiser to wait. At a previous meeting of the Public Health Committee fault was found with medical men for reporting cases that were not typhoid fever as that disease, but the statistics of the union fever hospital show that cases of mistaken diagnosis (that is, cases sent in as typhoid fever which turn out not to be so) are fewer than those recorded in the metropolitan fever hospitals. This sort of criticism does not meet the real facts which are that in a comparatively new city like Belfast typhoid fever—a preventable disease—is never absent and at times, as at present, assumes a serious epidemic form. The duty of the Public Health Committee is to find out first what is the cause of this most discreditable state of affairs and secondly, to put an end to it. A number of years ago the corporation, seeing that the fire brigade was in an inefficient condition, reorganised it, so that now people from all parts come to see it. At present they are making most advanced and elaborate arrangements for technical education. Why do they not reorganise their Public Health Department and bring it up to modern requirements? Until this is done there is little hope for improvement in city hygiene and sanitation in Belfast.

The Local Government Board of Ireland.

The constant quarrelling between the Local Government Board and the various local authorities in Ireland is deplorable. Quite recently the Board issued a sealed order directing the Downpatrick Board of Guardians to appoint a midwife in the Strangford District, but on Sept. 21st it was resolved by 17 votes to 2 to test the validity of this order in the law courts, and the solicitor of the guardians was ordered to employ counsel to apply for a writ of certiorari in the King's Bench. Then there is a standing dispute between the Belfast Board of Guardians and the Local Government Board as to the expenditure of a sum of money in the building of a new board room. The Local Government Board refuse so far to sanction this—and they are quite right, as there are lots of more pressing needs such as the building of a new nurses' home; but still the question arises, as the chairman put it, Are the affairs of the Belfast Union to be managed by the representatives of the people or by the Local Government Board? Constant wrangling is taking place all over Ireland in reference to the nursing regulations issued by the Local Government Board. Either there is great difficulty in interpreting the Irish Local Government Act or the Central Board in Dublin is not well advised and is weak.

Sept. 24th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

being attended to than if they were only ordinary travellers. Among the passengers were Dr. de Valcourt, Dr. Charles Leroux, Dr. Bucquoy, a member of the Academy of Medicine, Dr. Masbrenier, Dr. Lacambre, Dr. de Zvan, Dr. Hirschfeld, Dr. Fayard, Dr. Olivier, and M. Raymond Poincarré, formerly a Minister, and others.

The Paris Hospital Attendants.

The Paris hospital attendants, both male and female, have recently held an important meeting. They demand immediate permission to form a union, a permission which is refused by the Prefect of Police on the ground that no class of municipal servants is allowed to form a union. They also demand that instead of being boarded and lodged as they are they shall be allowed to keep their present salary and be free to board and lodge themselves how and where they please at their own expense. One result of this reform will be that their retiring allowance, which as matters stand at present is calculated upon the amount of their salary, due deduction being made for the cost of their board and lodging, would in future be calculated upon the whole of their salary without deduction. Finally, they ask for the formation of a nursing school and also that they shall be paid during their eight days' annual holiday as well as during their two periods of military service which last for 28 and 13 days respectively. The president of the meeting was M. Artreux, a *surveillant*, assisted by M. Malbos and M. Iger, *infirmiers*. These gentlemen, together with M. L'Héritier, spoke and laid the claims of their class before the meeting. The following resolution was carried unanimously:—

> The hospital attendants, both female and male, in this meeting, held on Sept. 7th, 1901, in the great hall of the Labour Exchange, beg to thank the Trades Committee for the efforts made on their behalf. The members invite all absent friends to join together with themselves in endeavouring to bring about as soon as possible the realisation of their just claims.

September Congresses.

Two important congresses have been held this month. That of the French Association for the Advancement of Science was held last week at Ajaccio, under the presidency of Dr. Hamy, a member of the Institute. The members had a great reception and the Mayor, M. Bodoy, in his speech expressed the hope that the important discussions upon climatology which formed part of the proceedings of the congress would result in great advantages for the town of Ajaccio and of Corsica in general, a country which had many sites eminently adapted for sanatoria, but one also where drainage of the marshlands was necessary for making the land really healthy. At Nantes on Sept. 23rd the Congress of Gynæcology, Obstetrics, and Pediatrics was opened. An interesting excursion had been organised for the members to the seamen's hospital of Croisic at Pen Bron. During the congress a monument was unveiled to the memory of two famous surgeons, Chassaignac and Maisonneuve, Professor Guyon being president of the proceedings.

Sept. 24th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Operative Results in Panophthalmia.

DR. C. BAUER, late assistant at the Zürich Ophthalmological Clinique under Professor Haab, has just published a report on the results of enucleation in cases of panophthalmia. As Professor Pflüger does not consider this operation justified, but wishes it replaced by the "exenteratio bulbi" (Paris Congress, 1900), it is desirable that all ophthalmological cliniques should report their results. Dr. Bauer writes on 53 cases which were operated on in the Zürich Ophthalmological Hospital from 1886 to 1900—viz., 45 men and eight women—the ages varying from 16 to 75 years. The origin of the panophthalmia was generally traumatic. The operations took place from three to 20 days after the injury (the average being seven days) and all the patients could be dismissed in from four to 14 days after the successful operation, the average date of dismissal being eight days after the operation. The report includes only very distinct cases of panophthalmia, an acute, purulent uveitis combined with severe inflammation of the surrounding tissues with swelling of the eyelids, protrusion and impeded motility of the bulbus oculi.[1] Bonnet's operation was always performed. The original chloroform narcosis has been supplanted by ether narcosis following an injection of morphine, this proving especially suitable in alcoholic patients. These 53 cases form 16 per cent., or about the usual average, of all the 320 cases of removal of the bulbus oculi which have been performed at the hospital during the past 15 years.

Gangrene of the Lower Extremity after Parturition.

Dr. E. Wormser reports one more of these very rare cases which he has observed at the Basle Lying-in Hospital; there are only about 20 such cases on record. A woman, aged 36 years, was suffering from purulent bursitis near the knee-joint when her sixth confinement came on. Notwithstanding every precaution—the abscess having been opened previously—the patient was feverish and on the twelfth day after the confinement she developed gangrene of the left foot and died three days later. The infection proved to be due to streptococci, and three injections of anti-streptococcic serum proved of no avail. As in some other similar cases, the relatives made legal claims against the medical attendant for mismanagement of the case, but the claims were not allowed.

Obituary.

I regret to report the death of two Zürich medical men. Dr. Hans von Wyss, who has many connexions in England, succumbed to apoplexy at the early age of 55 years; he was Professor of Legal Medicine and the author of a book on the subject. He had been a member of the sanitary council (*Sanitätsrath*) for many years. Dr. Max Freudweiler also died suddenly, a very promising young man, aged 30 years, and lecturer (*privat-docent*) on Hydrotherapy at the Zürich University.

Zurich, Sept. 23rd.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Canadian Medical Association.

THE thirty-fourth annual meeting of this association was held at Winnipeg, in the province of Manitoba, on August 28th, 29th, and 31st. Although Winnipeg is situated some 1300 miles from the leading centres of medical thought in Canada the attendance, which reached over 175 members from all parts of the Dominion, was greater, with one exception, than that of any meeting and was pronounced the best in every respect since the Association was organised in 1867. Every province in the Dominion was represented, with the single exception of Prince Edward Island, one delegate travelling 3000 miles to attend the meeting; and there were several visiting physicians from the United States. The social functions have never been surpassed; the special excursion through the great wheat belt of Manitoba offered to the members of the Association by the Canadian Pacific Railway was a trip thoroughly enjoyed by all and not soon to be forgotten. Dr. H. H. Chown of Winnipeg was the president, while Dr. F. N. G. Starr of Toronto discharged the duties of secretary. One of the oldest practitioners in the West, Dr. J. H. O'Donnell of Winnipeg, delivered the address of welcome and gave the history of the growth of the medical profession in that section of the Dominion from 1869 onwards—a time when Winnipeg was only an outpost of civilisation. The question of the formation of a Medical Defence Union was presented by Dr. Russell Thomas of Lennoxville, Quebec, who was delegated by the St. Francis District Association of that province to hand over to the Canadian Medical Association a scheme of medical defence which was already in operation in the eastern townships. The Canadian Medical Association unanimously adopted this scheme and forthwith organised a Medical Protective Union or Physicians' Protective Union, with its headquarters at the capital, Ottawa, and with Dr. R. W. Powell as president, Dr. McKinnon as secretary, and Dr. James Grant, jun., as treasurer, all being well-known practitioners.

A very able Presidential Address was delivered by Dr. Chown who made some interesting references to the future of the city of Winnipeg and the Province of Manitoba. Although less than 10 per cent. of the arable land of the province was under cultivation, the farmers of Manitoba would this year have a crop estimated at 85,000,000 bushels of grain. He referred to the water-supply and the sewerage system of Winnipeg, which with a population of 45,000 got its water from an artesian well 17 feet in diameter and 48 feet deep, and although they had been pumping for months a supply of from 2,000,000 to 3,000,000 gallons per day there was not the slightest evidence of any diminution of the amount flowing in The well was supposed to tap an underground passage which ran from Lake Manitoba and as this lake was 130 miles long the supply was inexhaustible Speaking of the question of tuberculosis he instanced cases of young farmers free from tuberculous taint l [illegible] bacilli, and separat [illegible] in whom tubercul [illegible] heredity, house [illegible] eliminated how w [illegible] these outbreaks?

---

[1] Haab's Atlas, Tab. 27 and Tab. 356.

The Address in Medicine was delivered by Dr J R. Jones of Winnipeg who is associated with the Manitoba Medical College. He took for his subject ' The Question of Medical Education " He thought that medical students generally entered upon the study of medicine poorly equipped in English and advocated a higher standard of medical matriculation He was in favour of a Dominion Medical Board, so that anyone with the proper qualifications could be registered in every province of the Dominion They should not only be Canadian, but Imperial, capable of registration in Great and Greater Britain He would not eliminate Latin, but would go a step further and advocate a more general knowledge of Greek The didactic lecture was adversely criticised and clinical methods of teaching, particularly the case method of teaching were upheld Dominion registration was a question thoroughly debated and discussed and delegates from all the provinces assured Dr Roddick of provincial support in this matter —Dr W S Muir of Truro Nova Scotia, read a very interesting paper on Infectious Pneumonia, reporting four cases seen in one family at a time when there was no influenza in the district

Epidemic Cerebro spinal Meningitis was the subject of a paper delivered by Dr James McKenty of Gretna Manitoba, who gave the history of an epidemic occurring in North Dakota, U S , during the winter and spring of 1893 It occurred within an area of 50 miles by 20 miles and about 70 persons were seriously ill 25 cases ending fatally Dr McKenty gave notes of 22 out of 30 cases occurring in his practice, the average age was 17 years , the youngest was 15 months and the oldest was 38 years The duration of the disease extended from 12 hours to 15 weeks —Dr A J Macdonnell of Winnipeg contributed a paper on Splenic Anæmia and reported a case —Dr J N Hutchison of Winnipeg read a paper on Physical Development in which he advocated periodical lectures, by duly qualified physicians, in the schools to separate classes of boys and girls on the subject of sex —Dr W H. Pepler of Toronto reported several cases of rheumatism, eczema, and varicose ulcer of the legs treated by superheated dry air, recording excellent results

Orthopædic Treatment of Deformities and Disabilities resulting from Diseases of the Nervous System with special reference to Tendon Transposition was the title of a paper contributed by Dr B E McKenzie of Toronto —Dr G A. Kennedy of McLeod, Alberta presented a paper on Mild Small pox which dealt with the recent outbreak of the disease in the North west Territories There had been 1500 cases and a noteworthy fact was that the greatest number of cases occurred among the French half breeds who had never been vaccinated , and further, Indians on reserves had not suffered to any great extent, as annual vaccination was the rule Not one case was seen or heard of among the Galicians Doukhobors, or Roumanians who had lately settled in the Canadian North west, and this was due to the fact that compulsory vaccination was the rule in youth with these people, and then they had been revaccinated on their recent passage across the Atlantic and at Halifax. 13 deaths had occurred from the disease.—Dr Montizambert the Director General of Public Health for the Dominion, in discussing this paper considered that it would be unfortunate if the impression went abroad that any doubt existed in the minds of the members of the Canadian Medical Association as to the true nature of the disease which had now been epidemic on the North American Continent for some years He considered that the facts presented in Dr Kennedy's paper relating to the Doukhobors and Galicians were the most valuable portion.—At the close of this discussion the following motion was unanimously adopted .—

> That in view of the general prevalence of small pox throughout this continent this Association desires to urge upon the profession and the public generally the necessity of vaccination and of revaccination

A very interesting case was that recorded by Dr J F W Ross of Toronto of Chronic Ulceration of the Stomach simulating Cancerous Disease in which the Operation of Gastro-enterostomy with the Murphy Button was Performed This occurred in a young woman aged 20 years who had been reduced to 75 pounds in weight At the operation a large growth was found at the pyloric end of the stomach It was looked upon as a hopeless case and temporary relief was secured by gastro enterostomy The patient fully recovered from all her symptoms and 11 months after the operation she weighed 140 pounds and on examination of the abdomen no mass could be felt and the patient was not suffering from any gastric symptoms at all.—Some Forms of Hyperacidity and their Treatment was dealt with by Dr C F Martin of Montreal in an interesting paper —On the evening of the second day Dr Thomas S Cullen of Baltimore, U S A , read a very interesting and valuable communication on Cancer of the Uterus with lantern demonstrations and following this was another demonstration on Skin Diseases conducted by Dr Francis J Shepherd of Montreal which was equally appreciated Both these demonstrations will take rank as features of the Winnipeg meeting of the Canadian Medical Association.—The Varieties and Distribution of the Bacillus Diphtheriæ and their Clinical Significance was a subject handled by Dr F F Westbrook of the University of Minnesota U S A , and was primarily from a laboratory point of view —Dr H A Bruce of Toronto showed a Hairy Tumour which had been extracted from the stomach of a young married woman aged 26 years. On opening the stomach the mass was found to be free in that organ, a portion extending through the pyloric end into the duodenum It was about 24 inches in length being about two inches in diameter at one end and gradually tapering to a point at the other The colour of the tumour was uniform throughout and of the same colour as the hair on the patient's head. There were no evidences of hysteria in the patient and the surgeon did not offer any solution of the problem as to how the hair got there —A case of Transplantation of the Ureter for the cure of Uretero vaginal Fistula was reported by Dr A Lapthorn Smith of Montreal. The operation performed for the relief of the patient was one which Dr Smith had seen Sänger perform at Leipsic three years ago This was the first time that this operation had been done in Canada Dr Smith stated that not a drop of urine had passed through the fistula since The patient had made an excellent recovery —Dr F Buller of Montreal read an able paper on Syphilis as Seen by [illegible] The largest share of the ophthal [illegible] was with the tertiary period [illegible] t which the syphilitic lesion [illegible] very important element in [illegible] did not believe in the [illegible] rdinarily administered [illegible] and appeared to favour the inunction method of treatment with grey powder —Dr H M Bracken the medical officer of health of Minnesota U S A , contributed a paper on the Recent Outbreak of Small pox in America He traced the origin of the disease as regarded the State of Minnesota where there had been a total of 9429 cases the disease still existing and having many centres of infection in that State He was of the opinion that small pox was probably imported into the United States by Cuban refugees before war broke out between that country and Spain Referring to the subject of vaccine, he said that it was frequently spoilt by not being kept in proper temperature, as it was frequently being shipped in cans which were too hot and then subsequently kept in warm offices He said that the health commissioner of Minneapolis kept all his vaccine in an ice box but of course, not frozen, and he always obtained good results Replying to a question in regard to isolation Dr Bracken favoured 18 days quarantine —The Necessity of a Recognition and Isolation of Trachomatous patients in Canada was the title of a paper prepared by Mr W Gordon M Byers of Montreal and read in his absence by Dr C F Martin of the same city The writer believed that there were many unrecognised and untreated cases scattered here and there throughout the Dominion of Canada especially in certain centres of the eastern counties of Ontario, some in Quebec and others in Manitoba Mr Byers thought that the attention of the Dominion Government should be directed to the exclusion of immigrants afflicted with trachoma.—Dr Montizambert stated that this question had been under consideration by the Government of Canada for some time —The Treatment of Typhoid Fever was dealt with by Dr. J. L. Bray of Chatham, Ontario, who now gave very little milk in feeding, but that little always peptonised. He believed in making the patient drink two or three quarts of pure water in the 24 hours. He sponged frequently with tepid water and thought that they got just as good results from tepid water as from sponging with very cold water or using the cold bath, and then it was not so distasteful to most patients. In hospital practice Dr. Bray used the electric fan after using the tepid water and he had found this plan very satisfactory, especially in young and sensitive children.

The Address in Surgery was delivered by Mr. O. M. Jones of Victoria, British Columbia, who was formerly an assistant of Mr. Treves. His address dealt mainly with Surgery of the Stomach, relating the deductions he had arrived at from his own experience of 26 cases. Gastro-enterostomy Mr. Jones considered the most important and most interesting part of the whole subject of surgery of the stomach. He said that nothing could be simpler than this operation performed with the Murphy button. He had used it in 14 cases and in only one case was there any trouble.—Dr. Henry Howitt of Guelph, Ontario, described a Surgical Procedure for the relief of Ovarian Pain which consisted in a number of cross-sections quickly made through the tense capsule of the ovary. Hæmorrhage and adhesions never gave any trouble.—Dr. Lapthorn Smith stated that he had never heard of this operation before and thought that it was original with Dr. Howitt.

On the last evening of the meeting a symposium on Tuberculosis was held which was opened by Professor Russell of the University of Wisconsin, U.S.A., who contributed a carefully prepared and exhaustive paper on Human and Bovine Tuberculosis and their Inter-relation. He considered his subject from the standpoint of animal industry and from that of public health.—Dr. A. J. Richer of Montreal dealt with the Sanatorium Treatment of Tuberculosis, a treatment made up of rest, outdoor life, over-feeding, and medical supervision, the latter being described as the keynote to success in phthisical treatment.—The Etiology and Early Diagnosis of Pulmonary Tuberculosis was the last paper read at the meeting and was contributed by Dr. Gilbert Gordon of Toronto. A very important discussion then ensued on this topic and a motion was unanimously adopted calling upon the Government of the Dominion of Canada to grant aid in the erection of sanatoria and also in the prevention and treatment of tuberculosis.

The city of Montreal was selected as the place of meeting in 1902 and a suggestion was left with the members of the Association that the meeting of 1903 should be held in the far-off province of British Columbia. The following were the officers elected for the ensuing year: President, Dr. Francis J. Shepherd of Montreal; treasurer, Dr. H. B. Small of Ottawa; and general secretary, Dr. George Elliott of Toronto.

Sept 17th.

Obituary.

WILLIAM LAKE ROBERTS, M.R.C.S. ENG., L.S.A.

MR. W. L. ROBERTS, senior honorary surgeon of the Bradford Royal Infirmary, died on Sept. 8th at his residence in Peel-square, Bradford. Mr Roberts, who was in his fifty-sixth year, was a native of Alford, Lincolnshire, and went to Bradford almost 30 years ago. He received his medical education at King's College, London, and became qualified as M.R.C.S. Eng. and L.S.A. in 1868. Before going to Bradford he was for a short time assistant house surgeon at Stockport. He was house surgeon at the Bradford Infirmary for 10 years, and upon resigning the position in 1880 his portrait was painted by order of the House Committee and hung in the board-room. At that period he entered into partnership with the late Mr. Herbert Spencer, to whose practice he succeeded. He was not only a man of whom everybody spoke well, but one of whom everybody thought well. Handsome in person, his upright, well-knit figure and clear, honest blue eye were only the index of a loveable, honest, frank, and modest character. As a surgeon and practitioner he was cautious, conscientious, and able; as a friend he was always the same—cheerful, quiet, and true. He has left a widow and one daughter.

Such is the life that was cut short on the Sunday night of Sept. 8th, after a long and painful illness, borne with the greatest fortitude and during which he to the last showed the same consideration for others and the same gratitude for all services rendered to him that had characterised him through life.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In September the following candidates passed in the subjects indicated:—

Surgery—H. Richardson (Sections I. and II.), Leeds; and C. W. Rowntree (Sections I. and II.), Middlesex Hospital.
Medicine.—C. J. E. Edmonds (Sections I. and II.), St. Thomas's Hospital; R. L. Jones (Sections I. and II.), Middlesex Hospital; G. J. W. Keigwin (Section II.), London Hospital; C. A. Lower (Section I.), Guy's Hospital and Bristol; and C. W. Rowntree (Sections I. and II.), Middlesex Hospital.
Forensic Medicine.—C. J. E. Edmonds, St. Thomas's Hospital; R. L. Jones, Middlesex Hospital; O. Millauro, Westminster Hospital; C. W. Rowntree [illegible] H. Smith, Birmingham.
Midwifery.—C. H [illegible] E. O. Libbey, Leeds; C. W. Rowntree [illegible] Taylor, Sheffield and Bristol; and J. [illegible] al.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—

C. J. E. Edmonds, R. L. Jones, G. J. W. Keigwin, C. W. Rowntree, and H. Smith.

UNIVERSITY OF DURHAM.—In the Faculty of Medicine the following candidates have been successful in the following examinations for the degree of Bachelor in Medicine:—

FIRST EXAMINATION.

Old Regulations.

1. *Chemistry, with Chemical Physics.*—Babaji Sarvottam Mankar, L.S.A., London Hospital.

New Regulations.

1. *Elementary Anatomy and Biology, Chemistry and Physics.*—Second-class Honours: Reginald Inglis Douglas, St. Bartholomew's Hospital. Pass list: James Henry Cooke, B.Litt., William Cowden, Arthur Beresford Jones, William Ernest Craven Lunn, and Richard Geoffrey Shaw Simpson, College of Medicine, Newcastle-upon-Tyne.
2. *Chemistry and Physics.*—Reginal Bigg, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; John Bowman Cooke, College of Medicine, Newcastle-upon-Tyne; Saville James Fielding, St. Thomas's Hospital; Archibald Finlay, London Hospital; James Glenny Gibb, St. Bartholomew's Hospit[illegible] Grant College, Bombay; Cyril [illegible] Markham, and Francis Henry [illegible] Newcastle-upon Tyne; Roland W[illegible] Owens College, Manchester; [illegible] London Hospital; and Edward Tate and Tys Visser, College of Medicine, Newcastle-upon-Tyne.
3. *Elementary Anatomy and Biology.*—Hugh Boyd Cunningham, Samuel Leslie McBean, and John Charles Norman, College of Medicine, Newcastle-upon-Tyne.
4. *Elementary Anatomy.*—Thomas Henry Bishop, Edinburgh University.

SECOND EXAMINATION.

Old and New Regulations.

Anatomy, Physiology, and Materia Medica.—First-class Honours: John George Ogilby Hugh Lane, M.R.C.S., L.R.C.P., Guy's Hospital, and Thomas William Maddison, College of Medicine, Newcastle-upon-Tyne. Second-class Honours: George Errington Lloyd, College of Medicine, Newcastle-upon-Tyne. Pass List: John Arthur Bell, St. Bartholomew's Hospital; Llewelyn Alfred Henry Bulkeley, Arthur Budd, Henry Mounsey Braithwaite, and Herbert Christal, College of Medicine, Newcastle-upon-Tyne; Edgar Fletcher Edmunds, University College, Sheffield; Harold Edgar Featherstone, Arthur Henry Hogg, and Norman Haliburton Hume, College of Medicine, Newcastle-upon-Tyne. William Watkiss Jones, Birmingham University; Sophia Bangham Jackson, University College, Cardiff; Frederick William Kemp, College of Medicine, Newcastle-upon-Tyne; Aurelius Victor Maybury, Guy's Hospital; Colin Francis Frederick McDowall and Constance Charlotte Robertson, College of Medicine, Newcastle-upon-Tyne; Leslie Martin Rosten, St. Bartholomew's Hospital; Stanley Robson, William Edward Stevenson, and William Seymour, College of Medicine, Newcastle-upon-Tyne; Francis Rupert Snell, St. Thomas's Hospital; Arthur Lewin Sheppard, William Tait Sewell, Frederick James Strachan, and William Lister Tindle, College of Medicine, Newcastle-upon-Tyne; and Samuel George Webb, Birmingham University.

NEW OPEN SPACE FOR FULHAM.—The borough of Fulham is to be congratulated upon having secured another recreation-ground for the use of the inhabitants. The Southfield estate, close to Hurlingham Park, consisting of 22 acres, has been purchased at a cost of £1500 per acre. The total cost, including the laying-out of the grounds, &c., is estimated at £45,000, towards which the London County Council will contribute £30,000.

THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON.—At the Bank of England £100 have been received from Sir Henry Irving and £50 from the Duke of Westminster for the Prince of Wales's Hospital Fund for London.—Among the latest contributions to the same Fund are the following:—Annual subscriptions—Mr. George Livesey, £25; Messrs. James Clarke and Co., proprietors of the *Christian World*, £21.

WELSH SEASIDE RESORTS.—At a recent meeting of the Merioneth County Council Dr. R. Jones, medical officer of health, reported that in the seaside towns of Carnarvonshire and Merionethshire the infant mortality was above the average and he thought that some of this might be due to the artificial feeding of infants whose mothers were engaged in the work of lodging-houses patronised by visitors. Dr. Jones also stated that the sleeping accommodation provided for domestic servants during the holiday season at Welsh seaside resorts was often very unsatisfactory. The council decided to send copies of the report to the educational and sanitary authorities of the county.

[illegible] TIFICATION ACT.—[illegible] 14th, Mr. T. Finney, a [illegible] charged with aiding [illegible] ear Haverfordwest, in exposing himself while suffering from scarlet fever on July 10th, 1901. The prosecution was conducted on behalf of the Haverfordwest Rural District Council. The evidence showed that on July 1st Mr. Finney saw the patient, who was suffering from a [illegible], and thinking it might be a cas[illegible] accordingly; he visited him a[illegible] and finding no symptoms came to the conclusion that he had made an error in diagnosis and that the man was not suffering from scarlet fever. He accordingly gave permission to the patient, who was away from home, to return to his own residence. Medical evidence showed that Mr. Finney had taken great trouble in the case and emphasised the difficulty of diagnosing scarlet fever in its early stages, and the magistrates rightly dismissed the case.

LITERARY INTELLIGENCE.—Dr. John Brown's "Horæ Subsecivæ" in the small handy edition, met with o much success last Christmas that Messrs. Adam and harles Black are getting ready for the coming Christmas a niform edition of "Dr. John Brown and His Sisters," by T. M'Laren. It will contain an introduction by Dr. John rown's brother, Professor Crum Brown, and will be illustrated with seven page family portraits and a photogravure ontispiece of Dr. John Brown.—Mr. Douglas Hall and Lord lbert Osborne have collaborated in a volume to be entitled "Sunshine and Surf" which will be published immediately y Messrs. Adam and Charles Black. It will contain their imressions of a year's wanderings in the South Sea Islands, nd will be profusely illustrated.—Messrs. Rebman, imited, announce the publication of the first three lumes of a "System of Physiologic Therapeutics," practical exposition of the methods, other than drugving, useful in the treatment of the sick and in the preention of disease, by English, American, French, and erman authors and edited by Solomon Solis Cohen, A.M., D., Professor of Medicine and Therapeutics in the Philalphia Polyclinic. The complete "System" will consist 11 medium octavo volumes, the first three of which are w ready—viz., Vols. I. and II. devoted to "Electroerapy" and Vol. III. comprising Book I of a treatise "Climatology, Health Resorts, and Mineral Springs." e remaining eight volumes of the series will be published short intervals.—The same firm have also ready or are out to issue the following:—Vol. I. of a new work on e "Practice of Medicine," by Dr. Henry Walter Syers, of e Great Northern Central Hospital; a new edition of Dr O. Thresh's "Water and Water Supplies"; a translation Professor Dr. R. Greef's "Guide to the Microscopic amination of the Eye," by Dr. Hugh Walker of Glasgow; E. Stanmore Bishop's new work on "Uterine Fibroomata, their Pathology, Diagnosis, and Treatment"; the rd edition of "The Pocket Formulary for the Treatment of sease in Children," by Dr. L. Freyberger; a work by Dr. nry Leffman and Dr. W. Beam on "Select Methods in Food alysis"; Mr Macleod Yearsley's translation of Professor Broca's monograph on the "Surgical Anatomy and rative Surgery of the Middle Ear"; the first volume of Professor Hemmeter's new work on "Diseases of the Intestines"; an entirely new edition, rewritten and much enlarged, of Dr. Louis Starr's "Diseases of the Digestive Organs in Children"; and "A Manual of Bacteriology," by Dr. H. M. Williams of Buffalo.

HOME FOR INEBRIATES.—On Sept. 19th the Bishop of Ipswich opened a home for inebriate women at Hamond Lodge, Terrington, near King's Lynn. This home has been established by the Church of England Temperance Society and can receive 33 inmates.

THE Council of the South Wales and Monmouthshire University College, Cardiff, held a meeting on Sept. 18th, when it was resolved to advertise for a successor to the late Principal Viriamu Jones at a salary of £1000 per annum.

LONGEVITY.—John MacDone, who died recently in Ennislainin, Connemara, is said to have been born in 1776 He was twice married, and his second wife, who is now 78 years of age, survives him. Like many of the inhabitants of Connemara, the deceased spoke only Irish. There does not seem to be any proper evidence that he had attained the age alleged

BRITISH MEDICAL BENEVOLENT FUND.—This fund, which has for its objects the affording of immediate pecuniary relief to distressed qualified members of the medical profession, their widows and orphans, and the granting of annuities to such after 60 years of age, has just issued its report for 1900. In the annuity department steady and satisfactory progress has been made. The capital has been increased by the purchase of £1600 Paisley Corporation 3 per cent. stock. The income from investments amounted to £2355 13s 3d, of which £2213 6s. 8d. have been paid away in annuities. During the year 16 vacancies were caused by death The increase of income has enabled one new annuitant to be elected, so that the total number is now 111 as against 110 on last year's list. In the grant department the committee report that the subscriptions show an increase upon 1899, though the amount is still below that of 1898. The donations include two special gifts of 200 guineas and 100 guineas respectively. For the donation of 200 guineas the fund is indebted to the liberality of an old friend and previous benefactor, Mr. G. E Rundle, F.R.C.S. Edin., of Looe, New South Wales. The donation of 100 guineas was a contribution from the president, Sir William Broadbent, who generously came to the rescue of the fund at a time when the balance available for grants had been reduced to less than £1. To both these donors the committee, in the report, tender grateful thanks. The grants actually paid in 1900 amounted to £1549. This sum was distributed among 165 cases, in amounts varying from £5 to £20.

NATIONAL REGISTRATION OF PLUMBERS.—The Lord Mayor of Birmingham, at a meeting of Master and Operative Plumbers held in the Council House on Sept. 17th, referred to the evils of bad plumbing which, he said, were great and far-reaching. In presenting a number of certificates granted in connexion with the National Registration of Plumbers he emphasised the importance of only duly qualified men being engaged in trades which were so closely identified with the health of the community. He said that it was gratifying to find that the reforms which were taking place in the trade were not forced upon them by outside pressure but arose from an almost spontaneous desire of the masters and men to uplift the trade and secure for it public confidence. A motion was proposed by Mr Bellamy, master plumber, seconded by Mr. Clarke, operative plumber, affirming that in the opinion of the meeting, representing the master and operative plumbers of Birmingham and the district, it would be a great public advantage if a measure be passed through Parliament securing an efficient system of registration, and urging that it is the duty of the Government to carry through such a measure in the public interest. Dr A Hill, medical officer of health of Birmingham, referred to the action taken in Parliament with that object The Lord Mayor observed that it was disappointing that Parliament was so tardy in giving attention to legislation that had common sense written over it—At Eastbourne the Mayor recently presented certificates of registration to 21 master and operative plumbers who had qualified under the conditions applying to the National Registration of Plumbers.

ROYAL COMMISSION ON ARSENICAL POISONING.—The Royal Commission on Arsenical Poisoning due to beer containing glucose made with arsenical sulphuric acid will probably resume its sittings at Westminster in the middle of October.

PRESENTATION TO A MEDICAL PRACTITIONER.—Mr. E. Rice Morgan, M.R.C.S. Eng., L.S.A., has been presented with an illuminated testimonial and a diamond ring by the inhabitants of Morriston, Swansea, and his friends on his return from a voyage round the world to recruit his health.

BEQUESTS AND DONATIONS TO HOSPITALS.—A bequest of £1000 has been made to the Royal Hants County Hospital by the late Marquis of Winchester who was killed in South Africa. About £5000 have been subscribed in response to a special appeal made by the hospital.—An anonymous donor has sent £1000 to the Friedenheim Hospital, Swiss Cottage, N.W., to endow a bed "in memory of John Thomas Emmett."

THE QUEEN'S JUBILEE INSTITUTE FOR NURSES.—On Sept. 21st a drawing-room meeting was held at East Cowes Castle to decide as to the best means of promoting the women's memorial to Queen Victoria, which is to take the form of endowing the late Queen's Jubilee Institute for Nurses. The meeting was held under the presidency of Lady Gort. Lady Adela Cochrane stated that the object of their gathering was to enlist the practical sympathy of the women of the Isle of Wight in the work, which was that of nursing the poorest of His Majesty's subjects in their own homes. The secretary stated that the Queen's nurses now numbered over 900, and reminded the meeting that the movement was founded by the late Queen in 1887, on which occasion Her Majesty contributed £70,000 from the women's Jubilee offering. It was decided to start a women's fund in the Isle of Wight.

A PROMISING CAREER has been cut short by the death at an early age of Mr. R. U. West who during his student days and also during a short period of actual practice had gained the warm esteem of both teachers and fellow students. Mr. West seemed well fitted to carry on the traditions of a family that had done much honourable service in the medical profession, his father, the late Mr. J. G. U. West, having been a highly respected practitioner in Stoke-upon-Trent and a member of the honorary staff of the North Staffordshire Infirmary, and his grandfather a well-known practitioner in Lincolnshire. Mr. West's death, which occurred on Sept. 3rd from enteric fever, contracted whilst acting as house surgeon to the Seamen's Hospital, Greenwich, was a cause of sincere grief to the members of the visiting staff who had much respect for him as an able, considerate, and loyal colleague.

son.—On Sept. 17th, at Beachlands, Deal, the wife of Lieutenant-Colonel P. H. Benson, I.M.S. (Mysore), of a son.

[illegible]

MARRIAGES.

tt—Baker.—On Sept. 12th, at St. Stephen's Church, Paddington, by the Rev. L. Titley, Sydney Richard Scott, M.B. Lond., M.R.C.S., L.R.C.P. Lond., to Ethel, daughter of the late George Baker of Shrewsbury.

lcox—Griffin.—On August 29th [illegible]

DEATHS.

her.—On Sept. 20th, at Upper Woburn-place, Francis Bonfield Archer, M.D., C.M., in his 64th year.

glas.—On Sept. 13th, at Bellingdon-road, Chesham, James Richard Alexander Douglas, M.R.C.S., L.S.A., in his 83rd year.

ran.—On Sept. 20th, at Marylebone, W., Lieutenant Colonel James Moran, M.D., I.M.S.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

QUERIES IN POOR-LAW ADMINISTRATION.

A correspondent asks us the following questions:—Is a medical officer obliged to resign his appointment and accept his superannuation when 65 years of age? Has the chairman of guardians (being a J.P. residing in another parish six miles away) a right to direct the relieving officer of this parish to take all pauper lunatics into the workhouse (out of this parish) after receiving notice from the district medical officer? In answer to (1) the Superannuation Act states that an officer "*may* be superannuated when he reaches the age of 65 years." The guardians, therefore, *may* call upon their medical officer to take his superannuation the moment he reaches the age of 65 years, or they may retain his services for a further period if they think that he is still "capable of performing the duties with efficiency." The answer to (2) depends upon the chairman as a J.P. having jurisdiction or not in the parish where the lunatic resides. If he has he can, by Section 14 (3) of the Lunacy Act, require the relieving officer to bring the lunatic before him at such time and place as shall be appointed in his order, and the place may be the workhouse. The chairman and J.P. has no authority to give a general order to the relieving officer. He can only give the order upon receiving notice that a person is deemed to be a lunatic. See Section 14 (3). The relieving officer can remove without an order under Section 20 The extract from Section 14 (2)—"in the place where the pauper resides"—refers to the jurisdiction of the justice, not to the place where the pauper is to be taken.

THE CAPACITY OF THE URINARY BLADDER.

To the Editors of The Lancet.

Sirs,—On July 24th last a primipara, aged 24 years, was delivered of a male child, stillborn. The child weighed 11 pounds, and the woman, who was very stout, carried it well forward. Nineteen hours after delivery over 50 ounces of urine were withdrawn with the catheter. On the following day the catheter was used twice, but subsequently the urine was passed in the natural manner, though with increased frequency. The patient was up before the tenth day and continued well, and remains so at the present date, the amount of urine retained being excessive with no impairment of function. This note is made by permission of Mr. F. Dymoke of Bristol.

I am, Sirs, yours faithfully,

University College, London, Sept. 11th, 1901. A. P. Walters.

⁂ The interest in Mr. Walters's note lies in the fact that there was no impairment of function, as the amount of urine drawn off is not very remarkable and has often been exceeded. The rapid recovery of the bladder in this instance is chiefly attributable to the patient's age. In older people atony is much more likely to follow over-distension.—Ed. L.

THE BATTLE OF THE CLUBS.

We learn that the post of surgeon to the Wanstead Foresters is at present vacant. The local practitioners have agreed among themselves to ask for a remuneration of 5s. per member per annum instead of 4s. A local medical man has been elected and the appointment offered to him at the old rate, which offer has been refused. The Foresters argue that all their courts in the eastern division of London pay but 4s. and they have therefore decided to look elsewhere for a surgeon. We need not reiterate all the reasons for medical men asking an increase in their salary. Suffice it to say that if working men's expenses have gone up so have those of medical men. But working men's wages have risen and it is only fair that the payments made to medical men should go up too. We are very glad that the practitioners of Wanstead are united, and can only urge any practitioners in the neighbourhood who may be approached to back up their professional brethren in their demands.

A "CONSCIENTIOUS OBJECTION."

On Sept. 16th a labourer appeared before the magistrates at Thorpe, Essex, applying for a vaccination exemption certificate for his child, the reason given being that the child's grandmother had died after vaccination. It appeared that the grandmother had been vaccinated when a child. The certificate was granted by a majority of the magistrates, two of whom were opposed to it.

LOCUM-TENENTS' FEES.

To the Editors of The Lancet.

Sirs,—Will you or any of your readers let me know how much a doubly qualified man is entitled to if called away to work as a locum-tenent for less than a week without settling any terms? A medical student friend of mine asked me if I would work for a medical friend of his who wanted to go out for a change I asked him the terms, to which he said that the medical man did not say anything about the terms in his letter or wire, and as there was hardly any time to lose asked me to leave town, assuring me that I would not be taken advantage of in any way. Consequently I left town at a very short notice on Thursday and stayed till the following Wednesday morning. For this period I was paid 30*s.* including 7*s.* travelling expenses. I put the money in my pocket without looking at it, but when I found that it was 30*s.* I was very much surprised but thought it better not to say a word until I had seen this medical student. He still told me that the medical man did not say anything about the terms when engaging me and asked me to write to that gentleman. So I wrote and asked five guineas and travelling expenses, minus 30*s.* already received. In reply the medical man said that he had offered 30*s.* and thought that was quite enough. Under the circumstances, when he had no direct correspondence with me and the terms were not told to me by the medical student, how much am I entitled to and how should I proceed to realise it? Thanking you for the trouble in anticipation,

I am, Sirs, yours faithfully,

Sept. 23rd, 1901. LOCUM.

⁂ The remuneration is altogether inadequate. We do not know what our correspondent's legal remedy may be, as he accepted the post without arranging for his fee, but he will be ill-advised to act without consulting a solicitor.—ED. L.

"INSUFFICIENT LAVATORY ACCOMMODATION IN GIRLS' SCHOOLS."

To the Editors of THE LANCET.

SIRS,—The insufficiency of lavatory accommodation in girls' schools to which Mr. Hughes Davies has very properly drawn attention in THE LANCET (Sept. 21st, p. 825) is certainly a condition which ought not to be allowed to continue, but I fear it would not be practicable to effect a remedy in the manner he suggests, through the local sanitary authority and the medical officer of health. I think, however, that this is a question which might very well be dealt with by the Medical Officers of Schools' Association. If the association would issue a memorandum addressed to the principals of schools I am quite sure the coöperation of medical officers of health could be obtained to secure its distribution. The conditions described by Mr. Davies are not to be found in at least one school with which I am acquainted, where the girls breakfast at 7.30 A.M. and have no definite school duties until 9.30.

I am, Sirs, yours faithfully,

Hereford, Sept. 21st, 1901. HERBERT JONES, D.P.H. Camb.

"MEMBRANOUS COLITIS?"

To the Editors of THE LANCET.

SIRS,—In answer to your correspondent "Worried" in THE LANCET of Sept. 21st, p. 826, I can tell him that I have obtained refreshingly good results in some cases of membranous colitis by throwing to the winds commonly accepted theories—salol, &c.—indeed, disregarding the local conditions as compared with treating the individual as a whole—generally a neurotic. Rest, food, and warmth are, I venture to say, the common-sense weapons we have wherewith to combat suchlike complaints—they are simple-sounding but much more powerful than any drug. Mr. Bunsby once said: "The bearing of this observation lays in the application on it." One of the chief arts of the physician lies in arranging, adjusting, and dovetailing simple remedies, thereby giving the chance which the *vis medicatrix naturæ* is longing for.

I am, Sirs, yours faithfully,

Crouch End, N., Sept. 23rd, 1901. F. ORTON, M.D. Dub.

To the Editors of THE LANCET.

SIRS,—"Worried" will find an account of mucous and membranous colitis, &c., in the Encyclopædia Medica, vol. ii., under "Colon"; also further reference in the *Medical Chronicle* for August, 1901, under "Mucous Colitis." If Bright's disease and amyloid disease can be excluded I would suggest, after attention to the teeth, a diet including green vegetables—e.g., spinach, meat, and fat—but limited as to carbohydrates, and these well cooked. Warmth also is necessary in clothing, &c., a regular mode of life, and as much change to a bracing and socially congenial atmosphere as is attainable. In any case much patience and avoidance of over-drugging are necessary.

I am, Sirs, yours faithfully,

Sept. 23rd, 1901. T. C. B.

To the Editors of THE LANCET.

SIRS,—As a patient of mine has suffered since her return from India, where she had hill diarrhœa and peritonitis 25 years ago, from membranous colitis with symptoms similar to those of the patient cited by "Worried," I may be able to give some hints, and shall be very thankful if they prove of use. She has been better for the last 10 years than previously, though a very experienced Indian practitioner who saw her at her worst, which was about 1882, thought the thickening of the cæcum would probably increase gradually and produce a fatal result. At that time, even between the attacks, there was usually pain after food, especially if vegetables were taken, so that she had to live mainly on meat. Later on the vegetable that suited her best was beetroot, plain boiled. More recently she has been able to take vegetables, but *not meat*, which produces headache and scanty urine. (When she was a child she could not take meat.) Before an attack there is often a feeling of terror or impending disaster; this, however is not uncommon in abdominal maladies. The attacks seem to have reference to damp and to vegetation, being most frequent in spring and when the leaves fall. Indeed, I have always tried to get her away to the sea, especially to Brighton, at those times. The sea acts both as preventive and cure and is better than any drugs. I should say that the heart is affected. It is dilated and when she is ill there is sometimes a systolic apex bruit, but not always. Now, as to treatment. Bael, bismuth, arsenic, sulphate of copper, and iodine applications do little or no good. I manage the case somewhat as follows:—In a very acute attack of right iliac pain she keeps to bed or sofa with constant large, hot linseed poultices, taking as little food as possible—only Brand's jelly, &c. I order Dover's powder if there is blood in the slime and glycerine suppositories if necessary (enemata increasing the pain). When improving the yelk of an egg mixed with a teaspoonful of flour relieves diarrhœa. Resorcin, one or two grains in water, is very soothing, also useful in minor attacks, but tends to constipate if continued long and affects the heart. After an attack is over I find pernitrate of iron useful in strengthening the bowel. The pain, I think, is worst when the membrane has been shed, leaving a raw surface. By the time the membrane is passed the pain is often better. I am very doubtful about the desirability of giving aperients. I believe an attack has frequently been averted by a timely visit to Brighton, and after an acute attack I generally find that as soon as she is sufficiently recovered to be carried downstairs and put into a cab and from that into the train a fortnight there sets her up again in a marvellous manner. Brighton appears to be specially suitable from the absence of decaying vegetation. I shall be very happy to g "Worried" any further information privately.

I am, Sirs, yours truly,

Woolwich Common, Sept. 21st, 1901. THEODORE MAXWEL

ORGANO-THERAPY 170 YEARS AGO.

IN our issue of July 13th, p. 94, we gave some examples of prescriptic by thirteenth-century practitioners of the school of Salerno, a more recently we noted that mandrakes still have a sale; but t following prescriptions which were published in 1731 show a deg of credulity hardly to be expected from "the father of mod chemistry and brother of the Earl of Cork." The book is said to written by "The Honourable R. Boyle, Esq., late Fellow of the Ro Society," for the benefit of "those poor Upholders of Families v cannot find or fee a Surgeon or a Doctor." Here are a specimens:—

FOR THE DYSENTERY.

Take *Pigs-Dung*, dry it, and burn it to grey (not white) Ash of these give about half a Dram for a Dose, drinking after th about three spoonfuls of Wine Vinegar.

FOR CONVULSIONS, ESPECIALLY IN CHILDREN.

Take *Earth-Worms*, wash them well in White-wine to clea them, but so as that they may not die in the Wine: Then u hollow Tiles, or between them, dry the Worms with a moder Heat, and no further than that they may be conveniently redu to Powder; to one Ounce of which add a pretty Number of Gra of *Ambergrise*, both to perfume the Powder, (whose Scent of it is rank) and to make the medicine the more efficacious.

TO PREVENT THE TOOTH-ACH, AND KEEP THE TEETH SOUND.

Let the Patient frequently rub his Teeth moderately with Ashes that remain in *Tobacco-Pipes*, after the rest of the Body h been consumed in Smoak; some time after, washing (if need his Mouth with fair Water not too cold.

FOR OBSTRUCTIONS, AND DIVERS DISEASES PROCEEDING THENCE.

Let the Patient drink, every Morning fasting, a moder Draught of his own *Urine* newly made, and (if it can convenien be) whilst 'tis yet warm, forbearing Food for an Hour or t after it.

AN UNCOMMON BUT EXPERIENC'D REMEDY FOR DYSENTERICA FLUXES.

Take the Bone of the Thigh of a hang'd Man (perhaps anot may serve), calcine it to Whiteness, and having purg'd the Pati with an Antimonial Medicine, give him 1 Dram of this wh Powder for one Dose, in some good Cordial, whether Conserve Liquor.

A CHOICE EXTERNAL REMEDY FOR A SORE THROAT.

Take *Millepedes*, Sows or Hogs Lice alive, and sew them between the Foldings of a piece of Linnen, and apply them to Throat in the form of a Stay, which is to be kept on all Night.

FOR AN AGUE.

Take of the Bone called *Platella*, of the Knee of a dead Man, a having reduced it to fine Powder, give of it as much as will upon a groat or a six-pence for one Dose, in any proper Conser or fit Vehicle.

κ. τ. λ.

"PRESERVING THE ELASTICITY OF INDIARUBBER."

To the Editors of THE LANCET.

SIRS,—The following hints may be useful to your correspondent Richards (THE LANCET, Sept. 21st, p. 826). I am indebted to t manager of a rubber factory for them. Rubber goods should be kept i temperature that does not fall below 60° F. (I keep mine in a cupboa at the back of which the kitchen chimney ascends). Tubes and tubu goods should be hung up or laid on a shelf carefully coiled, free fr bends, kinks, or pressure. Rubber sheeting should be rolled on a sti not folded. Water-bottles, air-beds, pillows, &c., should be sligh inflated with air and be thoroughly dry before being put away. T or three days' exposure in a temperature of 70° F. will soften rub articles that have become hard.

I am, Sirs, yours faithfully,

Sept. 23rd, 1901. EXPERIENCE.

H. [illegible] the information. We cannot, [illegible] may really mean. We [illegible] societies the manage- [illegible] er, but sometimes an advertisement of this character will get into our columns because on the face of it it is innocent.

F. W. A.—The advertisement is presumably inserted by the house agent and not by the medical man in question. If his attention were called to it we are sure that he would be the first to insist upon its withdrawal.

During the week marked copies of the following newspapers have been received:—*Yorkshire Post, Kent and Sussex Courier, Mining Journal, Rochester and Chatham Journal, South African News, Leeds Mercury, Coventry Standard, Windsor and Eton Express, Reading Mercury, Liverpool Daily Post, Local Government Journal, Lancaster Observer, Bristol Mercury, The Times, Southwark and Bermondsey Recorder and South London Gazette, South London Chronicle, Epsom Herald, Surrey Advertiser, Dorking Advertiser and County Post, Essex Telegraph, Essex County Standard, Hertfordshire Mercury, &c.*

[illegible] GRADUATES' COLLEGE AND POLYCLINIC [illegible] —4 P.M. Mr. H. Tilley: Clinique. (Throat.)

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1901 are on sale. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also on sale Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Office, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
